"The Lord Provost rose and said, that the Council had now arrived at that stage of the proceedings when it became their duty to take into consideration the filling up of the vacant chair of Surgery in the University of Edinburgh—one of the most important duties, he believed, that had fallen to their lot to perform, since they (the Reformed Council) had the honour of being appointed to the management of the city's affairs, and he might safely say, that the eyes of Europe were fixed upon the Council in anxiety respecting the result of their deliberations on the subject. It therefore became the Council most seriously to consider well the step they were about to take. He confessed, that for his own part, he had at first, when the vacancy took place, entertained the idea that there was none between that chair and Mr. Liston; but, *upon further consideration, and hearing the opinions of others, he had seen reason to abandon that idea. He had all along endeavoured to avoid proposing any thing at that board but what was agreeable not only to the Council but to the public; and he had accordingly kept his ears open to public opinion. He had hence discovered that the eyes of the greater part of the public were concentrated on another individual than the one he had anticipated.* He should not hurt the feelings of any one, by drawing comparisons between one candidate and another; it was not called for, and would, therefore, be highly improper. The minds of the Council being made up as to their choice, it was desirable that the matter should not be allowed any longer to be hung up, creating hopes and desires, as it would unnecessarily do, in the minds of other candidates; but that they should proceed at once to nominate the person whom they conceived best fitted for the situation. He should therefore propose, that an offer of the vacant chair should be made to Sir Charles Bell. (Cheers.) In making this proposition it would not be expected that he should dilate upon that gentleman's professional merits, a task for which he was utterly unable; he should do more justice to the merits of so distinguished a physiologist by merely mentioning his name. (Renewed cheers.)"

* From the "Scotsman."

LECTURES ON THE DISEASES OF THE NERVOUS SYSTEM.

BY M. ANDRAL.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

INFLAMMATION OF THE BRAIN.

Anatomical characters of Encephalitis—Causes—Symptoms—Affections of Motion (Convulsions, Cramps, Paralysis)—Affections of Sensation—Special Senses—Affections of the Natural Functions (Digestion, Circulation, Respiration)—Treatment.

INFLAMMATION of the nervous centres does not manifest itself by symptoms so well

marked as those which indicate the inflammation of other organs—as of the lungs, for instance; that of the brain, in particular, derives a part of its obscurity from the circumstance of its often being difficult to distinguish what belongs to it and what to inflammation of the meninges. Besides, the disease is not so common as some would have us to suppose; unless, indeed, we call every disorder of these organs, with anatomical change, by the name of inflammation, as appears sometimes to have been done. To characterize inflammation of the nervous centres, an assemblage of phenomena is required, into such details concerning which I shall enter by and by, as will, I trust, render the subject complete.

We must not, for example, mistake for inflammation of the brain the nervous symptoms which accompany follicular ulceration of the bowels. There are few children who sink under an acute disease without exhibiting nervous symptoms, where, nevertheless, there has been no encephalitis; the disturbance having been entirely the effect of sympathetic reaction. Towards the close of many chronic diseases, we observe a variety of symptoms referable to the brain, without, however, our having any right to assume that there is encephalitis: for instance, we see this in phthisical patients, in whom the brain is rather in a state of anemia; nor is this fact of light importance in practice. In typhus fever, too, the nervous system acts an engrossing part; there is disturbance in the brain as well as in the alimentary canal, but inflammation is no more necessary for the one than the other.

The brain may be disturbed in its functions without inflammation; thus nervous delirium—delirium tremens—is not the result of inflammation, for it resists the abstraction of blood, and yields, as if by magic, to large doses of opium; a medicine which, as we know, is very injurious in inflammation of the brain.

Encephalitis is divided into inflammation—first, of the brain—secondly, of the cerebellum—thirdly, of the central white substance. Acute inflammation of the brain may be general, which is very rare, or partial, which is much more common. One hemisphere may be attacked while the other remains free, or a portion only of a hemisphere may be inflamed; in short, I have here to repeat what I have already said with regard to congestions. Inflammation may have its seat on the external surface, in the internal white substance, or in the cerebellum.

Anatomical characters.—These are invariable, whatever may be their seat. They consist of injection, more or less deep, of the grey or white medullary matter, just as in simple congestion. Are there any characters by which it may be determined with certainty whether the injection result from inflammation, or only from hyperemia? There are not; and, indeed, simple congestion often passes insensibly into inflammation; a circumstance which is not peculiar to the brain, for it is not always possible to distinguish positively between mere engorgement of the lungs and recent pneumonia. But we do not find injection alone in all such cases. Thus sometimes the cerebral tissue shows manifest tumefaction, resulting from an increased determination of blood, so considerable as to augment the bulk of the hemispheres. The brain being rendered more voluminous, and being contained in a cavity which admits not of distention, is compressed; and various symptoms are developed, corresponding to the degree of this compression. When the skull-cap is removed, we frequently see the diseased hemisphere project above that which is sound; the convolutions, pressed and indented into each other, no longer exhibit their enfractuosities. The inflamed hemisphere, being more bulky, tends to encroach upon the other, and disturbs it by its mechanical pressure.

Inflamed nervous texture also changes in its consistence; and we have here a general law of pathological anatomy in regard to inflamed organs: thus softening of the brain may be a consequence of inflammation; and with inflammatory softening, when acute, there is always injection. This does not hold good, however, in chronic inflammation. One of the terminations of inflammation, in all organs, is ulceration: this is, indeed, rare in parenchymatous structures, and also in the brain; but it has been observed in this organ.—(Scoutteten and Abercrombie.)

Every inflamed tissue tends to the formation of pus; the brain does not escape the general law, and the presence of purulent matter is a satisfactory proof that there has been inflammation, except in those cases where this is the result of abscess formed by metastasis. The pus may exist at first in the state of diffusion, but by degrees, and in proportion as the disease advances, if the patients are not carried off too soon, the molecules of pus are collected into masses, and abscesses are formed: this is a kind of abscess, however, which is much more common as a consequence of chronic than of acute inflammation. Sometimes there is but one such deposition, sometimes there are several.

It is doubtful whether inflammation of the brain ever terminates in gangrene, although some examples of this kind are re-

corded in the Memoirs of the Old Academy of Surgery, and M. Lallemand has related another in his excellent work.

But these lesions are not the only ones that may be met with; thus the meninges become inflamed here as the pleura does in pneumonia, and it is the affection of the meninges which gives origin to the effusions found between the membranes, or in the ventricles, and which occasion great modifications in the symptoms.

Causes.—These are often the same as what we have seen to produce congestion; but there are some also which act more especially in causing encephalitis. In the external world, insolation plays an important part, and the same holds good with spirituous liquors taken to excess. External violence, which has little part in the production of congestion, is all-powerful in exciting inflammation; among these are blows, falls, &c. with or without solution of continuity. The blow, indeed, may not have been upon the head itself, but have communicated a shock to the whole body, and produced a commotion which only becomes completely dissipated to give place, sooner or later, to genuine inflammation. If there has been solution of continuity, it may either have affected the bone or only the soft parts which cover it; and it is by no means very rare to see inflammation of the brain resulting from a simple wound of the hairy scalp. Again, there are cases wherein the bone externally is sound, but the inner table being fractured, its periosteum becomes the seat of inflammation, which thence extends to the adjacent parts.

Sometimes the causes of encephalitis are foreign bodies, which wound the nervous pulp. A projectile may cause inflammation, with or without remaining in the part. But the action of all these causes is far from being instantaneous, and it is not uncommon for it not to become manifest until after the lapse of a very long period. Thus in certain cases a bullet has been known to remain several months in the midst of the brain, without producing any accident; shortly after, violent symptoms have suddenly become developed, death has taken place, and, on post-mortem examination, the projectile has been found to be surrounded by a layer of inflammation.

We may also discover causes of encephalitis in certain chronic affections of the brain; thus apoplectic cysts, acting as foreign bodies, excite genuine inflammation around them. Numerous accidental productions do the same, such as malignant tumors or tubercles, particularly in children, who have them at the same time developed in various other organs. It is around these that inflammations form, generally chronic, but sometimes acute. Now it is not the tubercles which prove fatal in such cases, for they may have existed long without producing serious mischief; but it is the inflammation excited around those productions which is the cause of death.

Among the causes we ought also to mention diseases, whether acute or chronic, of the meninges; and also caries, exostosis, &c. of the bones of the head, particularly the pars petrosa of the temporal.

The organs of sense give us the following causes:—In the eye, internal ophthalmia, such as violent iritis; in the ear, inflammation affecting the deep-seated parts; in the nose, inflammation of the olfactory surface, particularly if it extend into the frontal sinuses. It is not uncommon to see intense, and even fatal, inflammation of the brain, result from the extraction of simple or malignant polypi from the nose.

With regard to the skin, inflammation of this on the face or scalp, in the different forms of erysipelas, may cause encephalitis; we must not, however, suppose that the delirium of a patient labouring under erysipelas always depends on inflammation of the brain, for it may be the result of a mere sympathetic re-action, or nervous disturbance; but it is requisite, when there is any doubt, to act as if we were certain that inflammation was present.

Nerves which communicate with the brain may be the points whence encephalitis originates. M. Bouillaud has seen an example of this kind, in which, after the application of ligatures on the nerves of the arm, violent pains were excited, which, spreading progressively along their course, soon arrived at the brain.

There is no organ the inflammation of which may not prove the occasional cause of encephalitis; but it is necessary to keep in mind that every disorder which accompanies such inflammation does not prove that this condition has also extended to the brain. Teething may also be enumerated among the causes, although it is congestion rather than inflammation which is produced.

Again, the brain may become irritated and inflamed simply by its own increased action, such as results from long-continued intellectual exertion, violent emotions, &c.

Symptoms.—These, as with regard to congestion, vary in proportion to the intensity, the extent, the nature, and the seat, of the lesion. Sometimes they become blended with the symptoms of acute meningitis. They may be divided into two series, according as they depend upon—1st, disorder of the functions of the brain; 2d, disorder of the functions of nutritive life.

Cerebral functions.— In the first series

are ranged the disturbances of intellect, motion, and sensation. The disturbance of intellect may be the predominant symptom, as in the phrensy of the ancients, and delirium in all its forms, furious or tranquil, taciturn or loquacious. The study of these numerous varieties contributes nothing to our knowledge of encephalitis; and, indeed, they are often idiosynchronous. Delirium may show itself alone without appreciable lesion of sensation or motion, or be attended by disturbance of both these; and what is remarkable, — in the most unequivocal inflammation of the brain, the intellect may regain its clearness from time to time. The same remission may also be observed in the derangements of other organs.

The delirium is increased by noise, and sometimes by the slightest degree of light. It continues during a period which varies, and is followed by coma more or less profound. There may be alternations of delirium and coma; and if the disease tends to a fatal termination, the coma shews a disposition to become permanent; nevertheless, death may take place during the delirium. The delirium becoming permanent, or succeeded by coma, or alternating with this, is very frequent in encephalitis. Sometimes, however, the intellect may remain entirely undisturbed during the whole continuance of this disease, particularly when it affects those parts only which are at a distance from the convolutions. Sometimes the intellect is disturbed only at the commencement; sometimes, entire at first, it becomes affected afterwards, its derangement being then added to those of sensation and motion. The intellect may regain its integrity after the recovery of the patient, or it may remain weakened for a longer or shorter time. Alienation, or mental debility, so as to prevent the individual from any continued exertion, may also take place. In some the memory is permanently impaired.

Affections of motion.—In some patients we observe as an unique phenomenon great agitation of the limbs, which are affected as with a kind of chorea. To this is often added starting of the tendons, similar to what occurs in follicular enteritis, even when there is no inflammation of the brain; but in encephalitis much more certain indications are afforded by convulsions, spasms, and paralysis, which are rarely found in any marked degree in merely sympathetic disturbances.

Convulsions.—The convulsions may implicate a great number of muscles at the same time, and produce singular distortions of the eye, grimaces of the face, or inability to speak. Sometimes we have preternatural movements of the limbs, which must be carefully distinguished from simple agitation. However, these convulsions alone do not suffice for the diagnosis of encephalitis, for we may also have them, though less violent, in typhus fever, where, indeed, they differ only in degree from the convulsions which attend inflammation of the brain.

The convulsions may be either general or partial, and may affect one or both sides of the body: if they be general, there may be some doubt in the case, but if they be limited to one side of the body, we may infer that there is something amiss in the brain.

Cramps.—This symptom consists, as is known, in permanent contraction of the limbs, with inability to produce extension by the most violent efforts; it is characteristic of the disease before us. These cramps, but slightly marked, and not constant in the first degree of inflammation, are strong and constant when there is softening. They are not met with in the enteritis of typhus fever; but in inflammation they may be seen at times in all the limbs.

Paralysis.—This may have a variety of seats: thus, it may attack the face, the limbs, tongue, pharynx, the muscles of respiration, &c. The paralysis may come on suddenly, and at the very commencement of the disease, but this is rare. In the great majority of cases the paralysis does not show itself till a more advanced period; it is usually preceded by convulsions, and more particularly by cramps; and then it is a symptom of the greatest importance; whilst, if it declare itself at the onset, it is just as likely to depend upon apoplexy. If, however, it be accompanied by delirium at the same time, we have more reason to suspect the presence of inflammation. In certain cases there is paralysis of one side and cramps of the other; or the same limb may be the seat of paralysis, convulsion, and cramp, alternately.

Affections of sensation.—We often observe pain of the head to manifest itself at the very commencement, and before the appearance of any other symptom. These pains are not an absolute sign of encephalitis, as they may also occur in meningitis. The pain is more severe in inflammation about the brain, than that which accompanies the onset of certain other diseases, such as typhus fever. The patients experience sensations which are quite peculiar; some think they hear a constant whistling, others are alarmed by loud and repeated detonations, and yet others are tormented by noises resembling the constant rushing of a torrent. When, in the course of any disease, the symptoms just enumerated come on, it behoves us to direct our attention to the brain.

Sometimes the general sensibility is exalted in an extraordinary degree; in other instances a paralysis of sensation accompanies the loss of motion.

Special senses.—In the first period, which is that of excitement or exaltation, we may observe in the eye that the pupils are contracted, and that there is intolerance of light; in the ear that there is extreme sensibility to sound, ringing, buzzing, &c. In the second period the senses are blunted, weakened, and sometimes even abolished. The sight is lost, the pupils are dilated and immoveable; the patients are affected with deafness, but the lesions of the sense of hearing are not always dependent on encephalitis alone; for it occurs also in typhus fever; but it is very rare to see it so completely abolished in this as it is in inflammation. It is the same with regard to vision. When we meet with complete blindness, it is a reason for suspecting that there is mischief in the brain. And further, the conjunctiva is never completely insensible to the touch when the fingers are applied to it in typhus; but this frequently happens in inflammation of the brain.

The disturbances of the nutritive functions come next.

Digestion.—This is often considerably affected; thus vomiting frequently marks the onset of the disease. In many persons, too, who are attacked with acute encephalitis, very obstinate constipation is often observed. With these positive signs there are others of a nature purely negative.—Thus, the tongue is natural, the abdomen soft and without distention; signs which are of importance when we have to establish a diagnosis between this disease and the enteritis of fever.

Circulation.—At the access of inflammation of the brain, if it be violent and general, the pulse is accelerated; but often, also, particularly when there is effusion, the circulation becomes slower; and lastly, if the inflammation, though acute, be partial, the pulse is, in a majority of cases, quite natural.

Respiration.—If the disease be intense, the breathing is embarrassed, becomes stertorous, and shows the same derangements as in those cases in which there is hæmorrhage into the brain.

In other respects the symptoms of acute encephalitis differ much, according to various circumstances: 1st, according to the nature of the lesion. If there be simple irritation of the brain, it is manifested by an exaltation of function and by delirium; if, on the contrary, there be compression of the cerebral substance, there is weakness, and tendency to collapse. 2nd, According to the seat of the lesion. Thus, inflammation of the cerebral lobes of the central parts of the ventricles, of the white or grey substances of the cerebellum, have each their special signs. I should here have but to repeat the observations which I dwelt upon so long in speaking of congestion.

To recapitulate, I may say, that in acute inflammation of the brain, the symptoms supervene and succeed each other in a manner which forms two distinct periods. The former is characterized by excitement: it is then that we have delirium in all its varieties, and that we often have, besides, violent agitation, convulsions, cramps, and similar phenomena. The latter period belongs to the state of coma, and the different forms of paralysis, with various symptoms characteristic of a diminution of the organic functions. But it is to be constantly kept in mind, that the phenomena which characterize these periods may be mixed up with one another, and are not always successive: they may alternate in their manifestation; and the disease, in certain cases, as it were begins with the second period, without there having been any thing preceding it which could be regarded as constituting the first stage; thus we may have paralysis without any antecedent convulsions. In others, the disease is limited to the phenomena of the first period, delirium, convulsions, and spasms; in the midst of which scene of excitement death takes place, before any of the signs of prostration indicative of the second period have arrived; so that the disease presents three different aspects, according as, 1st, it goes through all its stages; or 2nd, the first period be wanting; or 3rd, it be limited to the first period.

If now we turn our attention to the mode of attack, we shall find it marked by important phenomena, but which are not always the same. Thus, in certain individuals, before the development of the assemblage of symptoms which mark acute inflammation of the brain, we observe an intense degree of fever, with indications of cerebral congestion; in a word, we have the inflammatory fever of the ancients, and gradually only do the characteristic symptoms of encephalitis display themselves. In others, whilst they are in the midst of health, and without any warning, delirium, with all its accompaniments, comes on, without any lesion whatever of motion. Are we, then, to conclude from this, that we have to deal with acute inflammation of the brain every time we observe fever with delirium? Certainly not; for I have seen more than one case in which typhus fever has begun with nervous symptoms of this kind: the circumstance is rare, indeed, but it is sufficiently established. Other persons, at the onset of acute encephalitis experience some sudden disturbance of motion, as convulsions, cramp, or paralysis, more or less general; and this mode of onset enables us to form

our diagnosis much more surely and more easily than in the two other forms previously described.

The cases to which we have alluded are of daily occurrence; but there are others which, being uncommon, ought, when they present themselves, to be noted with the greatest care. It is thus that sometimes the disease does not make itself manifest by any of the capital symptoms already pointed out; but the observer is struck exclusively by the presence of complete inability to articulate; this symptom alone being present for a longer or shorter time, to be followed, however, by the other phenomena. Abercrombie relates the case of a young man, fifteen years of age, who, after having bathed, fell asleep exposed to the rays of a burning sun. On waking, he had lost the power of speech, but there was no other lesion of the motive powers, and the intellect remained entire. After three or four days his mind became disturbed, all the phenomena of encephalitis came on, and he died. The post-mortem examination proved the brain to be inflamed in the most acute degree, with numerous points of suppuration in both hemispheres. It is worthy of remark, however, that there was nothing observed in the anterior lobes. This is, without doubt, a remarkable case, in which the loss of speech continued, for more than three days, to be the only symptom; and certainly, from this solitary fact it was impossible to divine before-hand the intensity and extent of the lesion.

In other cases, it is on the side of the nutritive life that the symptoms commence which are to end in the manifestation of acute cerebral inflammation. Thus, before any other phenomenon occurs, we may have vomiting more or less obstinate, depending upon the sympathy produced on the stomach by the brain.

Duration.—Acute inflammation of the brain is very variable in its duration: sometimes it proves fatal in less than twenty-four hours; at others the disease does not come to a close till after the lapse of a much longer period; it may remain acute for thirty or forty days, or even for two months, and then pass into the chronic state, ending in a return of perfect health, or leaving behind imperfections, more or less severe, of intellect, motion, or sensation. Thus the motions of certain muscles remain imperfect; and particularly those of the eye are occasionally so modified after an attack of encephalitis, that strabismus is produced. In other cases the fingers are affected, more or fewer of them remaining contracted. The sensibility may also be observed to be impaired in various parts of the body.

Treatment.—This does not differ essentially from that of other acute inflammations: there are, however, some particular indications to be laid down. First, we must commence, in every case, by the abstraction of blood; and the rules by which we are, in this respect, to be guided, do not differ from those already mentioned in speaking of cerebral congestion. After the bleeding follows a means of great power, namely, the application of cold; but we must take care not to employ it until we have combatted the re-action by repeated depletions. If the re-action has not become developed, cold may be employed much earlier, but never without the greatest precaution. The application of cold before the re-action has been overcome renders this much more violent, and capable of producing the most fearful mischief. Another inconvenience attached to the employment of this means is, the production of too powerful a collapse, and coma which nothing can remove. It is necessary to be aware of these two dangers, between which it must be our object to steer our course. However, it were better to have too powerful a re-action, which we have the means to combat, rather than a state of collapse, against which all our means are frequently unavailing. The application of cold is to be made by ice to the head permanently, and not temporarily, or for short periods; the intervals, under such circumstances, affording the re-action time to be re-produced. The ice must not lie heavily on the head; it must be pounded, and renewed from time to time. There are some persons who receive a disagreeable impression from the cold, not for a short time only, which is common, but permanently; and when this happens, its use must be discontinued. To others, again, the application of the ice affords the greatest comfort, and often leads to the restoration of the intellect, the cessation of the delirium immediately following the application of the ice, which such patients beg for with importunity.

Cold may also be employed in another form, that of affusion of water at the temperature of 22, 21, 18, or 16 degrees (cent. ther.); very rarely, however, beneath this. These affusions are applied at intervals longer or shorter, according to circumstances; and each may last at first from one to two minutes, but may afterwards be continued much longer. In certain cases it has been contrived to keep a constant current over the head and face, a moderate temperature. In yet other cases cold water is made to fall drop by drop from a certain height on the head; and some physicians attach great importance to this method. I have seen a young woman, having all the signs of a severe encephalitis, perfectly cured after being subjected to this plan during four days; this occurred in the practice of M. Recamier. Cold is certainly a powerful agent,

but one the management of which requires great skill: improperly applied it may be productive of the most formidable mischief. General cold affusion has been used in cases of violent febrile action: the whole surface of the skin may be sponged with water, or vinegar and water, care being taken to keep the head cool at the same time.

Revulsives.—All the medicines belonging to this class have been used—sinapisms, and blisters to the limbs, neck, or even to the head itself; but not until after the reaction has been subdued by depletions or by cold. There are some individuals, however, who do not bear cutaneous irritation, and in whom the febrile symptoms are reproduced as soon as the skin becomes red from a blister or sinapism.

In general it is necessary to employ cold in conjunction with bleeding, rather than revulsives, the premature use of which is particularly to be feared. Nevertheless, revulsives are sometimes of great advantage in cases of profound collapse, or persistent and still increasing coma; a state which must not be confounded with the condition in which mere sinking prevails, and in which the use of revulsives is often dangerous. In the former, which requires the employment of active revulsion, the eye is insensible to light, the pupil motionless, and the general sensibility almost entirely extinguished. In cases of this nature occurring in infants, I have covered the scalp with a large blister, with decided advantage; but I have carefully avoided this plan as long as there was any heat of skin, or the least remains of erethism.

Mercurial preparations have been held up as specifics in acute inflammation of the brain, but I have never seen them of much avail. They have been rubbed in on the back of the head or neck, but the action of such means is not rapid,—a certain time is required, and meanwhile the disease advances. They cannot conquer the disease unless they have an opportunity of encountering it. Calomel has been given internally, particularly in the treatment of infants, where, indeed, it has been regarded as a specific; but it is doubtful whether it acts otherwise than as a purgative. In recurring to the cases which have been published, you will find that the calomel has acted upon the bowels, evidently producing revulsion, as all purgatives do; perhaps, however, it may be more efficient than other medicines of this class, because it exerts little irritation, may be given in very small doses, and has no disagreeable taste, — circumstances which are of great importance in the treatment of infants or of adults affected with delirium.

ABUSE OF THE STOMACH-PUMP.

THE LUNGS INJECTED WITH MUSTARD.

To the Editor of the Medical Gazette.

Sir,

In a clinical lecture by Dr. Watson, contained in your last number, I find some excellent remarks on the abuse of the stomach-pump; and a case is mentioned where a quantity of *chalk mixture* was found in the texture of the lungs after death. Believing that the injection of the lungs is an accident of more common occurrence than is generally supposed, and having several times observed the rude and careless manner in which this valuable instrument is used, I am induced to make the following circumstance public:—A few years ago, on entering one of the wards of the hospital with which I am connected, I found one of the resident medical attendants actively engaged, injecting by means of the stomach-pump, a strong infusion of mustard, in a case of poisoning from opium. The patient, a young man, was evidently in a state of asphyxia, and in a very few minutes before the instrument was withdrawn, expired. Being present at the post-mortem examination, I was surprised on finding the lungs remarkably distended, and that they did not collapse when the chest was opened. On making a section of them, the individual who had introduced the stomach-pump, immediately exclaimed, "How thickly they are filled with *miliary tubercles;*" and really they had a very curious appearance, the texture of both lungs being thickly studded with small yellow spots, which, from the odour, we soon recognized to be caused by the presence of the mustard, which had been forcibly injected into the numerous vesicles of this organ instead of into the stomach. The same substance was found in the bronchial tubes, trachea, and larynx. This is not the only instance of similar culpable negligence which has come to my knowledge, and by directing attention to the subject, you may probably be the means of saving several lives.

Your obedient servant,

Chirurgus.

Dec. 14, 1835.

[The writer has given us his name.—E.G.]

COX'S DISPENSATORY.

NOTE FROM MR. COX IN REPLY TO MR. NIAARP.

To the Editor of the Medical Gazette.

Sir,

Perceiving in your journal of last week an attack on my character by Mr. Niaarp,

I trust you will allow me a small space for reply.

The New London Dispensatory published by me, and designated by Mr. Niaarp as a cheat and imposition, contains a translation of the *last* London Pharmacopœia, and has been considered by competent judges a correct and valuable work. The epithet *new*, was used to distinguish it from the London Dispensatory of Dr. Thomson.

There has been no alteration in the London Pharmacopœia, as is well known, since 1824, at which time the work referred to was published, therefore on appending to it, this year, some hundred pages of new matter, viz. the Formulary of M. Magendie, I was justified in calling it an improved edition. I may also add, that the original price was 10s. 6d.; and although the above important additions have been made, the price has only been raised to 12s. Surely this is no aggression upon the purse of any one except the publisher.

As to my imposing on the public by selling Lawrence's Lectures in such a form that only twenty out of eighty-eight lectures are introduced, I have merely to say that the work was not published by myself, but by Mr. Westley, of the Strand. Mr. Niaarp should have mentioned that he only gave 5s. 6d. for the book, which, if purchased in the numbers of the Medical Gazette, would have cost him more than two guineas.—I am, sir,

Yours respectfully,
E. Cox.

St. Thomas's-Street. Southwark,
Dec. 10, 1835.

BENEVOLENT DISPENSARY.

To the Editor of the Medical Gazette.

Sir,

May I request you will apprise your numerous readers that the practice of the Benevolent Dispensary (the prospectus of which appears as an advertisement in the wrapper of this day) is free to the medical public, and that I shall feel a pleasure in relieving any poor patients my professional brethren may send to the charity.

I remain, sir,
Yours very obediently,
Frederick Salmon.

12, Old Broad-Street,
Dec. 8, 1835.

LITERARY INTELLIGENCE.

A Brief Memoir of the late Sir William Blizard, as read before the Hunterian Society, with Additions, by William Cooke, Esq., will shortly be published.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

December 17, 1835.

Joshua Goodwin Kershaw, Bradford, Yorkshire.
Rudd Lucas.
John Stedman, Godalming.
William Martin, Reigate.
Thomas Haymes, Great Glenn, Leicestershire.
James King, London.
James Bell Metcalfe, London.
Andrew Joseph Doyle, Lewes, Sussex.
John Daniel Vittoria Packman, Puckeridge.
Alfred Henry Vallack, Kingsand, Devon.
Richard Godfrey Lowe, Bristol.
Thomas Kean, Reading.
John Collier Seccombe, Plymouth.

WEEKLY ACCOUNT of BURIALS,

LECTURES
ON
MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XIII.

REPTILIA.

HAVING finished two of the vertebrated classes—Mammals and Birds—we advance to *Reptiles*. Here, however, we find no pharmacological agent; but I shall very briefly notice, *en passant*, two or three animals interesting either from having once yielded something to medicine, or from their poisonous qualities.

Reptilia.—In the Cuvierian arrangement, the term Reptilia (from *reptilis*, creeping) includes not only the reptiles commonly so called, as turtles, lizards, and snakes, but those denominated Batrachia (from βατραχος, *a frog*), or the amphibious animals. The impropriety of this method is now generally admitted; and by most late writers Reptilia and Amphibia form distinct classes. I follow their example.

Reptiles, properly so called, have the following characters:—Their blood is cold, with elliptical globules; the heart has two auricles; the respiration pulmonary; the generation oviparous (in some cases being ovo-viviparous); and their skin is furnished with scales: hence they are termed by Blainville the *Squamifera*.

We subdivide them into three orders, thus:—

			Orders.
REPTILIA	having extremities	no teeth	Chelonia—as the Turtles.
		teeth	Sauria—as the Lizards.
	no extremities	....	Ophidia—as the Snakes.

Order 1st—*Chelonia.*

The Chelonian reptiles, or tortoises, are recognized by the strong bony or horny shields with which their bodies are defended. The upper shield, called *carapace*, back-plate, or buckler, is formed by the immoveable expanded ribs; while the lower shield, termed *plastron* or breast-plate, is constituted of the pieces representing the sternum. The mouth has no teeth, the upper jaw closing over the edges of the lower. Some are terrestrial, others aquatic: the latter usually have their feet more or less webbed (as in the *Testudo caretta*). Those tortoises that inhabit the sea are denominated turtles.

Three tortoises have been employed in medicine; namely, the *Emys europæa*, the *Testudo lutaria*, and the *Testudo græca*. From these have been obtained a broth or soup (*jus testudinis*), a jelly (*gelatina testudinis*), and a syrup (*syrupus pectoralis testudinum*); all of which were formerly recommended as restoratives and pectorals in phthisical complaints.

The *Chelonia midas* is the green or edible turtle, the "green fat" of which is the delight of the epicure, the glory of the alderman, and an important article of food to the tropical navigator.

Order 2d—*Sauria.*

The Saurian reptiles have an elongated body, a mouth armed with teeth, four legs, and a tail. None are now employed in medicine, though the *Scincus officinalis* was formerly used as an aphrodisiac.

Order 3d—*Ophidia.*

This order has been so called from ὄφὶς, *a serpent.*

Cuvier makes three families of it; namely—

Fam. 1. The *Anguis.*—The animals of this family are similar in several respects to some of the Saurians (lizards), but they are without feet, and have a third eye-lid. The *Anguis fragilis*, usually called the *blind* or *slow worm*, is a native of this country. When handled, it easily breaks, each of the pieces continuing to move for some time afterwards. It is perfectly innocent, though its bite is vulgarly believed to be fatal. The scales of this genus are very small, and have a similar form in all parts of the body.

Fam. 2. *The True Serpents.*—This family contains both venomous and innocent serpents. The *Viper* (*Vipera communis*) may be mentioned as an example of the first, and the *common ringed snake* (*Coluber natrix*) of the second: both are indigenous. The latter is very common: it is ash-coloured, with black marks on its sides, and a white ring (formed of three white spots) on the neck.

Fam. 3. *The Naked Serpents.* — This family includes only one genus—that of *Cæcilia.*

Vipera Communis.

History, &c.—This animal was very anciently known: it is mentioned in the Bible, and by Aristotle. It has received a variety of names: in this country it is usually called the *Adder*, and less frequently *Viper.* By some zoologists it is called *Coluber berus*, by others *Vipera berus.* I have adopted Cuvier's designation.

Description.—The length of the animal is about two feet, varying a little more or less. Its colour is liable to considerable variation, depending on age, sex, climate, locality, &c.: so that mere varieties have been sometimes considered as distinct species. Dr. Leach makes three varieties: —

1. The *black viper*, so called from its colour.

2. The *blue-bellied viper*, in which, while the back has a browner tinge than usual, the belly has a shining blueish-black appearance, somewhat similar to polished steel.

3. The *red viper* is of a bright red colour above, has a heart-shaped mark on the head, and a dark spot near the extremity of the tail.

The head is shorter, broader posteriorly, and flatter than the common snake. Along the back, from the neck to the tail, you observe a black band, usually formed by the junction of rhomboidal figures. This band, although important as distinguishing the animal from the common snake, varies considerably in its appearance, being sometimes continuous, sometimes interrupted. When continuous, it frequently forms a waved or zigzag line; when distinct, the spots may be roundish, oval, rhomboidal, or rectangular. On the top of the head are observed two black lines, which unite anteriorly, but diverge posteriorly, so that we have the initial (V) of the animal's name: these lines are separated by a brown spear-shaped mark. On each side of the body is a stripe of roundish or subtriangular spots. The abdominal scales vary from 142 to 148 (usually they are about 146); those under the tail are from 30 to 40 pairs (generally about 39). The tail is shorter than in snakes.

The *poison apparatus* consists of a gland, (fig. 78, *b*), an excretory tube (*d*), the poison or dental sac (*e*), and the fangs, tusks, or stings (fig. 79). Each of these requires a brief examination.

First, let us notice the *gland.* It is placed behind the orbit, above and in front of the angle of the mouth. It is elongated, somewhat triangular, and slightly flattened, about $3\frac{1}{2}$ lines in length, and at its widest part about 2 lines broad: the apex of the gland is turned forwards, the base backwards. There are two coverings to it, both apparently tendinous: the external one, which seems to be the compressor of the glands (query, should it be regarded as the buccinator muscle?) is attached anteriorly by a tendon to the nostril; posteriorly it is continued to the junction of the two jaws. The internal layer dips down into the gland, so as to divide it into four or five lobes, each of which has a small excretory duct, and is composed of little sacs containing the yellow poisonous matter.

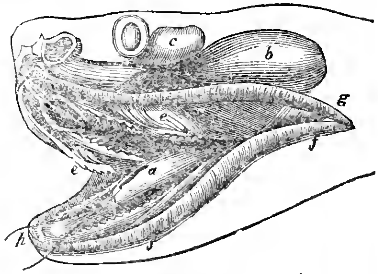

Fig. 78.—*Vipera Communis.*

a, Fissure of the pomum Adami.
b, Poison gland.
c, Lachrymal gland.
d, Excretory duct of the poison gland.
e, Poison sac.
f, Inferior maxillary salivary glands.
g, Superior maxillary salivary glands.
h, Tongue.

The excretory tubes of all the lobes of the gland unite to form one common *excretory duct*, which leaves the gland at its anterior or narrower portion, and passes downwards and forwards to open into the poison bag.

The *dental* or *poison sac* is an oval musculo-cutaneous bag, which projects into the mouth, where it is covered with a callous margin, and is perforated by a slit at the apex. Through this slit passes the poison fangs, which may be regarded as the osseous tubes of the sac.

The *poison fangs*, *tusks*, *teeth*, or *stings*, are sometimes single, sometimes double or treble: they are contained in the poison sac, and are so attached by a ligamentous substance in a hole in the upper jaw, that they are moveable. They are curved, and when not in action, the concavity is directed towards the roof of the mouth; but when the animal is about to bite, the concavity is backwards. From the base to the apex on the convex side of the tooth is a canal formed by a slit.

FIG. 79.—*Fang of Vipera Communis.*

Use of the poison apparatus.—When the animal opens his mouth for the purpose of biting, the elevators of the upper jaw compress the gland; a little of the poison passes along the excretory tube into the dental sac, and from this through the canal of the tooth into the bottom of the wound.

This poison apparatus ought probably to be regarded as part of the salivary organs, the poison gland being analogous to the parotid. In this respect we have an analogy to the poisonous salivary organs of the Arachnida.

Properties of the viper poison.—It has an oily appearance, but in reality is of a gummy nature, and has neither acid nor alkaline properties. It is without taste or odour; is somewhat viscid, and sinks in water, but may be readily mixed with it; it is not coagulable by heat. No chemical analysis of it has been made.

Effects.—The Abbé Fontana made more than 6,000 experiments with this poison. He employed more than 3,000 vipers, and had 4,000 animals bitten. His results, therefore, are worthy of confidence, since they are drawn from such an extended experience. The following is an abstract of some of the most important of them:—

Applied to the tongue, viper poison was neither acrid nor burning: it had, in fact, no determinate taste. When swallowed pure, and in large quantity, it excited a disagreeable, though indescribable, kind of sensation in the mouth, and which continued for five or six hours. On the conjunctival and olfactory membranes it had no irritant or even obvious action. Fontana poured the venom into incisions made with a lancet, but never obtained any evidence that the poison caused pain at the moment of application. It produces no obvious effect on the blood drawn from the body. Injected into the jugular vein of rabbits, the animals screamed violently, and died in convulsions within two minutes: these effects, however, were not uniform, for in some cases the animals survived several hours.

The symptoms produced by the bite of the viper are the following:—Pain in the part, commencing within a few minutes after the bite, augmented by pressure, and extending up the limb. Tumefaction, at first accompanied with paleness, then with redness, and subsequently with lividity and a gangrenous appearance; great hardness of the part. Syncope, or tendency to it; pulse frequent, small, and irregular; respiration difficult; cold sweats; vomiting, with extreme sensibility of stomach; sometimes pain in the umbilical region, and yellowness of the skin; disordered vision; sometimes convulsions, and disturbance of the intellectual faculties. A discharge of dark and subsequently sanious blood takes place from the part; and, when death occurs, gangrene appears. It is not frequently fatal in the human subject.

There are a considerable number of curious circumstances connected with the action of this poison, which I cannot here enter into. Such are, the non-operation of it on certain animals (the cold blooded, as the leech, the viper, &c.); its inactivity when swallowed, even in the human subject; the quantity required to produce death in various animals; the condition of the viper as affecting the result of the bite, &c. &c. These are all interesting topics of inquiry, but I must refer you for an account of them to Fontana's work.

Treatment.—The local treatment consists principally in making pressure around the part. This may be effected by placing a tight ligature around the limb, or by means of a cupping-glass applied to the part. The operation of the latter agent depends simply on the pressure of the edges of the glass, and is independent of the vacuum. Some years since, in conjunction with the late Mr. Ellerby, I performed a number of experiments on the agency of the cupping-glass in pre-

venting the action of certain energetic poisons; and we found that if a wooden ring be substituted for the cupping-glass it was equally efficacious. Where pressure cannot be conveniently made, caustics may be applied, with the view of decomposing the venom. If the parts are already swollen, scarifications may be resorted to.

The general treatment consists in the use of energetic stimulants and sudorifics, especially ammonia. The patient should be placed in bed, and every means taken to promote perspiration, by the use of warm liquids, &c.

AMPHIBIA.

The class *Amphibia* (so called from αμφις, on both sides, and βιος, life) constitutes the fourth order of reptiles, called Batrachia in the Cuvierian arrangement. Their characters are as follows:—The skin is without scales, and hence they have been termed the *Nudipelliferæ*; the heart has only one auricle and one ventricle. In the early period of their existence they respire by branchiæ, like fishes; but subsequently these organs shrink and disappear, while the lungs enlarge and come into action.

None of these animals are employed in medicine. The esculent frog (*Rana esculenta*) is used on the continent as an article of food. Both this and the common frog (*R. temporaria*) were formerly used medicinally. In old pharmacological writers we meet with various preparations of these animals; for example, two kinds of ointment (*Emplastr. de ranis sine et cum mercurio*), and several preparations of the spawn (*sperma ranarum*), such as, a distilled water, oil, plaister, &c.!! The tree frog (*Hyla viridis*, or *Rana arborea*) has also been employed.

PISCES, OR FISHES.

These animals are characterised as follows: the skeleton is for the most part osseous, though in many it always remains cartilaginous or fibro-cartilaginous; and on this is founded the primary division of the class. There is, however, a distinction between their cartilage and that of animals and birds; namely, by boiling in water it cannot be reduced to gelatine. But the most important distinctions between fishes and other vertebrated animals exist in the organs of circulation and respiration. The heart contains only two cavities, and corresponds to the right side of this organ in mammals: thus, the auricle receives the venous blood, and the ventricle propels it through the pulmonary (or rather branchial) artery to the branchiæ. The blood is cold, and its particles are elliptical. The respiratory organs are branchiæ or gills, in which the blood is submitted to the influence of the air, which is dissolved in the water. For the most part fishes are oviparous; but in some (the shark, for example), the eggs are hatched within the body of the mother: these are called ovo-viviparous. Their body is covered with scales; they have no mammæ; and their extremities are converted into fins; whence Blainville designates this class *Pinniferæ*.

Cuvier makes nine orders of fishes, thus:—

1. *Acanthopterygii* (so called from ἄκανθα, a thorn, and πτέρυξ, a fin), of which the perch and mackarel are examples.

2. *Malacopterygii abdominales* (from μαλακος, soft, and πτέρυξ), as salmon, carp, &c.

3. *Malacopterygii subbrachia*, as the flat fish.

4. *Malacopterygii apodes*, containing the eels, &c.

5. *Lophobranchii* (from λόφος, a tuft or crest, and βράγχία, branchia), of which the hippocampus is an example.

6. *Plectognathi* (from πλέκω, to tie or connect, and γνάθος, the jaw), as the porcupine fish.

7. *Sturiones*, or the sturgeons.

8. *Selacii* (from σέλαχος, a kind of cartilaginous fish), as the skate, the torpedo, &c.

9. *Cyclostoma* (from κύκλος, a circle, and στόμα, a mouth), as the lamprey.

These nine orders form two series:—

I. One called *Chondropterygii*, or the *cartilaginous fishes* (from χόνδρος, gristle, and πτερυξ, a fin).

II. The second termed *osseous fishes*.

Here is a tabular view of the arrangement of the orders, taken from Dr. H. Edwards's *Elémens de Zoologie*.

FISHES — ORDERS.

- Skeleton osseous; superior maxilla complete; (*osseous fishes*) ......
  - Superior maxilla moveable ....
    - Branchiæ pectinate ....
      - Anterior dorsal fin with osseous rays; some osseous rays to the anal fin, and ordinarily one to each ventral fin .... *Acanthopterygii.*
      - All the rays soft, except sometimes those of the first dorsal or pectoral fins (*Malacopterygii*)
        - Ventral fins behind the abdomen .... *M. Abdominales.*
        - Ventral fins suspended to the shoulder *M. Subbranchia.*
        - No ventral fins .... *M. Apodes.*
    - Branchiæ disposed in round tufts .... *Lophobranchia.*
  - Superior maxilla united to the cranium .... *Plectognathi.*
- Skeleton cartilaginous; superior maxilla replaced by the palatine bones; (*cartilaginous fishes*, or *Chondropterygii*) ....
  - Branchiæ free at their external edge; one orifice only for each operculum ..... *Sturiones.*
  - Branchiæ adherent at both edges; many branchial openings ....
    - Inferior maxilla moveable .. *Selacia.*
    - Maxillæ united in an immoveable circle......... *Cyclostoma.*

Of these orders the only one I have to notice is *Sturiones*, which contains the *acipenser*, yielding us Isinglass.

Acipenser.

History.—The term Acipenser is applied by modern naturalists to designate a particular genus of cartilaginous fishes, called, in English, sturgeons. But the word is met with in the old writers, and was used by them to indicate a fish much esteemed by the Romans, and which was brought to the tables of the wealthy by decorated servants, with great pomp, adorned with flowers, and accompanied by music. It has not been accurately ascertained what kind of fish was here employed, but it is generally supposed to have been an *Acipenser:* Cuvier thinks the *A. ruthenus*. Macrobius states that this custom was not confined to the Acipenser, but was common to all favourite dishes.

Etymology.—Authors are not agreed as to the etymology, or even the proper mode of spelling the word acipenser, some using one, others two *c*'s. We have, however, the authority of Lucilius and of Martial for using only one. Those who employ two *c*'s adopt the opinion of Sipontin, that the word is derived from *accipiendo*, because this fish is frequently taken at table. I have, however, seen no etymology that carries with it even probability.

Generic characters. — The sturgeons are remarkable for the longitudinal rows of bony tubercles, or plates, with which their bodies are more or less covered. These parts are exceedingly interesting to us in tracing the development of animals, from the lower to the higher tribes. As Dr. Grant has observed, these plates are a remnant of the superficial shells of the invertebrata. The snout of the sturgeon is lengthened and obtuse, and is furnished with four *cirri*, tendrils, or beards. The mouth, which is placed completely beneath, is small, and destitute of teeth.

Species.—The species of acipenser are badly determined. In Brandt and Ratzeburgh's Medizinische Zoologie, they are arranged in three subdivisions, thus:—

A.—*Husones*, including *A. Huso*, and *A. Schypa*.

B.—*Sturiones*, comprehending *A. Sturio*, *A. Lichtensteinii*, *A. Güldenstädtii*, *A. Stellatus*, and *A. Ratzeburgii.*

C.—*Sterleta*, containing *A. Ruthenus.*

Three substances are obtained from this genus; namely, *caviare*, *fish cartilage*, and *isinglass*. The first is prepared from the roe of the *Acipenser Huso*, *A. Güldenstädtii*, *A. Stellatus*, and *A. Ruthenus*. Isinglass is prepared from the swimming bladder of the same species. *Acipenser Sturio* yields a

good caviare, but which is not met with in commerce. I do not think it necessary to enter into a description of the species; those who wish to do so may consult Brandt and Ratzeburgh's work.

The sturgeons are sea fish, but frequent the mouths of large rivers for the purpose of spawning. The great fisheries for them are those of the Caspian. Here is a tabular view of the number of fish caught, with the products, for two years:—

Fisheries of the Caspian.

Year.	Number of Fish taken.			Products.			
	Sturgeon. *A. Sturio (?)*	Sevriouga. *A. Stellatus.*	Bielouga. *A. Ruthenus.*	Caviare.		Isinglass.	
				Pouds.	lbs.	Pouds.	lbs.
1828	43,035	653,164	23,069	34,860	1	1,225	27
1829	68,325	697,714	20,391	28,420	7	1,092	22

This table is taken from a review of the "Official Report on the Fisheries of the Caspian, made to the Minister of Commerce at St. Petersburgh," contained in the "Athenæum" for 1833. I may remark, that it is not improbable the specific names of the fish are not correctly given. The *poud* is equal to about 40 lbs.

Of the swimming bladder of fishes.— As isinglass is prepared from the swimming bladder of the sturgeon, it is necessary I should make a few remarks on this organ in fishes generally.

You are no doubt well aware that the horizontal progression of fishes is effected by the tail, while the processes of turning, stopping, &c. are performed by the fins. But it is necessary that these animals should have the power of rising or sinking in the water; and it is evident that this could only be effected either by enabling the fish to vary his specific gravity, or by means of a great muscular effort. In the great majority of instances nature has adopted the first method; in some cases the second.

In a very considerable number of fishes we find placed immediately under the spine, in the middle of the back, and above the centre of gravity, a membranous sac filled with gaseous matter, and which is denominated the *air bag*, or, from its supposed assistance in the motions of the animal, the *swimming bladder*. In the cod (*Gadus morrhua*) it is denominated the *sound*, and forms an article of food much sought after. In the sturgeons and some other fish, it consists of one bag only; but in carp (*Cyprinus vulgaris*) there are two, one placed anterior to the other, and communicating by a short tube. In most fish this bag communicates with the gullet, or stomach, by a canal or excretory duct, called *ductus pneumaticus*: the length of which is liable to considerable variation; and in some (as the *Salmo thymallus*, or grayling) this canal is altogether wanting. The form, size, and structure, of the swimming bladder, are subject to considerable variation. It is composed of three coats—

1st, An internal, highly vascular coat.

2dly, A tendinous, or, in some, probably a muscular coat.

3dly, It is covered externally, to a greater or less extent, by peritoneum.

In some fish a glandular apparatus exists on the inner side of the bag, which is supposed to be the organ secreting the gaseous matter. Mr. Langstaff has beautifully injected this gland in the conger (*Muræna conger*). In the sword fish (*Xiphias gladius*) the internal structure of the bag is cellular.

The gas contained in the swimming bladder consists for the most part of nitrogen, but mixed with oxygen, and sometimes with carbonic acid. Lacepede asserts he found hydrogen in the air bag of the tench (*Cyprinus tinca*). The relative proportions vary not only in different species, but in animals of the same species, arising probably from the age, size, season, locality, &c. Sometimes there is no oxygen present, or it may be less than one per cent.; in other cases the proportion of this gas is greater than that found in atmospheric air. Thus, in fish residing at considerable depth in the water, there have been found from 69 to 87 per cent. of oxygen. What is the source of these gaseous matters? Evidently they must either be derived from the atmospheric air, or they are the result of secretion. The latter opinion seems to be the more probable, since, in some fish, the air-bag does not communicate with the gullet, and in others

we find a glandular apparatus, supposed to be for the purpose of this secretion.

That one use of this bag is to enable the fish to rise and fall in the water, seems in the highest degree probable. If a few minnows be placed in a glass of water, under the receiver of the air-pump, and the air gradually exhausted, you see the animals rise to the surface of the water, by the expansion of the contents of this bag, and bubbles of air are emitted from the mouth. If the air be then re-admitted into the receiver, the fishes immediately fall to the bottom of the water, and are incapable of rising, except now and then, by a great muscular effort. In the natural state of the animal, therefore, it is presumed that by the compression or dilatation of this sac, effected by the surrounding muscles, the fish is enabled to alter its density, and thus to rise or sink in the water. The flat-fish (as the sole and flounder) are unprovided with an air-bag, and hence they can only rise in the water by a great muscular effort. It has, however, been objected, to this physiology, that eels, which have a swimming bladder, live at the bottom of rivers, while sharks, which roam at all depths, and mackarel, which pursue their prey at the surfaee, have none. Hence some authors have been led to regard this organ as forming part of the respiratory apparatus—that is, as secreting sometimes oxygen, sometimes nitrogen; and, when there is a ductus pneumaticus, of evacuating these gases.

Preparation of isinglass. — The remarks now made on the anatomy and physiology of the swimming bladder, prepare us for the proper comprehension of the nature of *isinglass*; the preparation of which is described, by Mr. Jackson, in the 63d vol. of the Transactions of the Royal Society, and also by Fischer, in a work entitled "Ueber die Schwimmblase der Fische," in 1795. The fish, when taken, are placed on rafts, where they are gutted. The roes are removed, to make caviare; the swimming-bladder, or sounds, are employed to form isinglass, or *ichthyocolla* (so called from ιχθυς, a fish, and κολλα, glue). When cut out, these bladders are slit open, then washed and placed in the air, with the inner lining upwards. The latter is then scraped off, and in this state the sac is dried, and forms the *leaf* isinglass. Sometimes, however, before it is quite dry, it is rolled up and bent like a horse-shoe, or a lyre, or a heart; and is then termed *staple* (of which there are two kinds, *long* and *short*). Sometimes it is folded up into little square packages, forming what is called *book* isinglass. Lastly, there is met with, in commerce, a kind called *purse* isinglass, which seems to be the sac dried unopened. The *pipe* kind is analogous to the purse, but longer. Sometimes it is brought over rolled up like a ribbon. Here are specimens of the different kinds. When brought to London they are picked into shreds. Formerly this was done by women and children; steam power is now used.

Commercial varieties and adulterations. — Independently of the varieties, arising from the mere form which isinglass is made to assume, we meet with various kinds in commerce, differing exceedingly in value; and as the adulteration is principally effected by mixing the inferior (the picked Brazilian leaf, for example) with the finer kinds, it is necessary I should put you on your guard: and here I may remark, that when reduced to the form of shreds, it is impossible to distinguish the finest from the

commonest kinds by the eye merely: this a wholesale dealer admitted to me. The only way of recognizing them is by boiling in water: the best kinds are completely soluble in water, the common kinds only partially so.

The following table will give you some idea of the varieties kept, though I have not inserted all (such as the second and third qualities of some of the sorts). I have thought it best to put the price to each (as given me now by Messrs. Simpson and Humphrey, of Little Britain, London), in order that you may know their relative values.

Form.	Designation.	Price per lb. £.	s.	d.
Staple	Long staple (finest), from Ural	0	13	6
	Short staple (Patriarch), from Astrachan, very scarce and dear.			
	Short staple (finest), ditto	0	14	6
	Samovey short staple	0	6	0
Leaf	Astrachan leaf (finest)	0	13	6
	Beluga leaf	0	11	6
	Brazilian leaf. from Para	0	5	0
	Samovey leaf (finest), from the Caspian	0	4	6
Book	Samovey book (finest) ditto	0	4	6
	Ural book	0	12	0
Purse	Siberian purse	0	9	0
	Hudson's Bay purse	0	7	0
Pipe	Pipe isinglass, from Maranham, Brazils	0	4	6
Ribbon	Ribbon isinglass, New York	0	4	0
Picked	Picked Astrachan leaf ....from 11s. to	0	14	6
	Picked Bazilian leaf	0	6	6
	Pickings (the brown ends)	0	8	6

Chemical properties.—The principal constituent of isinglass is gelatine; and the purity of it is determined by its complete solubility in water. John gives the following as the result of his analysis of isinglass:—

Gelatine	70·0
Osmazome	16·0
Membrane not soluble in water	2·0
Free acid (lactic?) with salts of potash, and soda, and phosphate of lime	4·0
Water	7·0
	100·0

It is probable, however, that this analysis is not quite accurate; for dried flesh, as Berzelius observes, does not contain more than 8 per cent. of osmazome; and if isinglass contained this quantity, we could not keep it dry when exposed to the air, on account of the deliquescent character of osmazome.

Here is a decoction of isinglass: we readily recognize the gelatine in it by the action of infusion of galls on it, and by its non-coagulability by heat and acids. Isinglass jelly is, in fact, the purest form of gelatine we can procure.

Physiological effects.—The local action of gelatine is emollient and demulcent; its remote action nutritive.

Uses.—Medicinally, we employ isinglass jelly dissolved in water or milk, and rendered palatable by a little acid and sugar, as a nutritious substance; or in diseases of the alimentary tube, as an emollient and demulcent.

In pharmacy, a solution of it with a little tincture of benzoin, is employed, brushed over silk, to form court-plaister. It is used also as a clarifying substance for coffee, wines, beer, &c. Some of the constituents (as the colouring matter) of these liquids unite with the gelatine and form insoluble compounds, which precipitate; and, in the act of precipitation, the gelatine incloses within its parts the matters rendering the liquid turbid.

DESCRIPTION OF A MICROSCOPIC ENTOZOON INFESTING THE MUSCLES OF THE HUMAN BODY *.

By Richard Owen, Esq., F.R.S. & Z.S.

Upwards of fifteen distinct kinds of *Entozoa*, or internal parasites, are already known to infest the human body; but none have been found of so minute a size,

* This interesting paper has just been published in the Transactions of the Zoological Society, vol. i. part 4.

or existing in such astonishing numbers, as the species about to be described.

The body of an Italian, æt. 50, who had died in St. Bartholomew's Hospital, was brought into the dissecting-room, and it was observed by Mr. Paget, an intelligent student, that the muscles presented an uncommon appearance, being beset with minute whitish specks. This condition of the muscles had been more than once noticed by my friend Mr. Wormald, the Demonstrator of Anatomy, in subjects dissected at St. Bartholomew's during previous anatomical seasons. His attention had been especially called to it on account of a gritty sensation sometimes perceived in dissection, from which circumstance, and the rapid blunting of the scalpels employed, he was induced to consider the appearance as being caused by a deposition of specks of earthy matter. Mr. Wormald having acquainted me with this fact, I expressed a desire to be furnished with portions of muscle so affected, and through my friend's prompt attention, I soon received ample materials for microscopical examination from the subject above mentioned*.

With a magnifying power of an inch focus the white specks in the muscle are seen to be cysts of an elliptical figure, with the extremities in general attenuated, elongated, and more opaque than the body (or intermediate part) of the cyst, which is, in general, sufficiently transparent to shew that it contains a minute coiled-up worm. On separating the muscular fasciculi the cysts are found to adhere to the surrounding cellular substance by the whole of their external surface, somewhat laxly at the middle dilated part, but more strongly by means of their elongated extremities, so as to render it generally a matter of some difficulty to detach them. When placed upon the micrometer they measure $\frac{1}{50}$ of an inch in their longitudinal, and $\frac{1}{100}$ of an inch in their transverse diameter; a few being somewhat larger, and others diminishing in size to about one half the above dimensions. They are generally placed in single rows, parallel to the muscular fibres, at distances varying from half a line to a line apart from one another; but sometimes a larger and a smaller cyst are seen attached together by one of their extremities, and they are occasionally observed slightly overlapping each other. If a thin portion of muscle be dried and placed in Canada balsam, between a plate of glass and a plate of talc, the cysts become more transparent, and allow of the contained coiled-up worm being more plainly seen.

Under a lens of the focus of half an inch the worm appears to be inclosed within a circumscribed space of a less elongated and more regular elliptical form than the external cyst, as if within a smaller cyst contained in the larger, like the yolk of an egg surrounded by its albumen and shell. The worm does not occupy more than a third part of the inner space. A few of these cysts have been seen to contain two distinct worms; and Dr. A. Farre, who has paid much attention to the subject, has shown me a drawing which he made of one of the cysts containing three distinct worms, all of nearly equal size.

The cysts vary in form as well as size, being more or less elongated, and the opaque extremities being further extended in some than in others: in a few instances only one of the extremities is thus produced. Occasionally the tip of one of the extremities is observed to be dilated and transparent, as though a portion of the larger cyst were about to be separated by a process of gemmation; and these small attached cysts are seen of different sizes, as it were in different stages of growth. This appearance, however, I conceive to be explicable without a reference of a power of independent vitality to either of the adherent cysts.

Besides size and figure, the cysts also differ in structure: in general they are composed of condensed and compacted lamellæ of cellular tissue, but a few are hardened by the deposition of some earthy salts, so as to resist the knife, and to break with a gritty sensation under pressure*.

In order to detach the worm from the cyst, which, from the minuteness of the object is a matter of some difficulty, I have found it best to select a portion of muscle which has been placed for a short time in spirits of wine. After separating the cysts from the surrounding fasciculi of muscle, and placing them, moistened with a little water, on a slip of glass, I have generally succeeded, on cutting off the end of the cyst, or tearing it open with the point of a needle, in ejecting the worm and the surrounding fluid in which it floats, by gently pressing on the cyst.

The little worm is usually disposed in two or two and a half spiral coils: when straightened it measures from $\frac{1}{25}$th to $\frac{1}{30}$th of an inch in length, and from $\frac{1}{700}$th to $\frac{1}{800}$th of an inch in diameter: a high magnifying power is consequently required for its examination. It is cylindrical and filiform, terminating obtusely at both extremities, which are of unequal sizes, tapering towards one end for about a fifth part of its

* The existence of the Entozoon was at the same time satisfactorily determined by Mr. Paget, with the assistance of Mr. Brown and Mr. John Bennett, at the British Museum.

* This change is probably dependent on the death of the inclosed worm, the traces of which are either very obscure, or altogether wanting, in these ossified cysts.

length, but continuing of uniform diameter from that point to the opposite extremity. It is only at the larger extremity that I have been able to distinguish an indication of an orifice; but this indication has been so constant in a number of individuals, examined under every variety of circumstance, that I have no hesitation in ascribing a large transverse linear mouth to the great extremity, which I therefore consider as the head.

A recently extracted worm, seen by a Wollaston's doublet before any evaporation of the surrounding moisture has affected its integument, presents a smooth transparent exterior skin inclosing a fine granular and flaky substance or parenchyma; and after carefully testing various appearances of more complex organization, that have on different examinations presented themselves, I now believe that the only structure that can safely be ascribed to this minute *Entozoon* is the simple one above described. It is not of a rigid texture, but is extremely fragile, and exhibits when uncoiled a tendency to return in some degree to its former state.

It is curious to watch the variety of deceptive appearances that successively present themselves as the worm dries by evaporation. One of the most constant is a succession of minute transverse rugæ, especially at the concave sides of the coils, which give a finely annulated character to the worm, but of which no trace can be perceived in the plump recent specimens when observed by a good doublet. Another appearance, which is more difficult to be accounted for, results from one, and sometimes two, longitudinal lines, extending over a greater or less proportion of the body; but these are not to be perceived in worms examined under circumstances least liable to cause deception. As evaporation proceeds, the wrinkling of the integument produces an appearance of the body being occupied by minute tortuous tubes, and a beautiful microscopical effect is thus obtained; but the fallacy of this appearance and its true cause are easily detected.

The test of coloured food could not be applied to elucidate the form of the digestive organs in the present instance: there was not any indication of the polygastric structure; which, indeed, was hardly to be expected, since it does not exist in those *Entozooid Infusoria* which most nearly resemble the parasitic species in question. There was no appearance of the parietes of an alimentary canal floating in a visceral cavity, and distinct from the integument of the body, as in the higher organized *Nematoid Entozoa*; nor could a trace of an orifice, or anus, be observed at the smaller extremity. I have been equally unable to detect a projecting spiculum, or hook, at either extremity, or any appearance of the worm having been torn from an attached cyst. The natural transparency of this species is such as not to admit of a doubt as to its wanting the ovarian and seminal tubes, and other characteristics of the complicated structure of *Filaria, Ascaris*, and *Nematoid Entozoa* generally.

Three species of small *Nematoid Worms* are described by Zeder as inclosed in cysts or capsules, and hence are termed by him *Capsularia*. Rudolphi, however, whose authority on this subject cannot be lightly disregarded, does not sanction or admit this genus in his "Systema Entozoorum," but refers the three species described by Zeder to the genera *Filaria* and *Ascaris*. The *Capsularia halesis*, or *Filaria capsularia* of Rudolphi, infests the abdominal viscera of the herring, and measures from half an inch to an inch in length: the intestinal canal is distinct, and is dilated at one extremity into a stomach. In the males the intromittent spiculum protrudes from the anal extremity, which is the largest. The *Capsularia salaris* and *Capsularia trinidosa* of Zeder, represent, according to Rudolphi, a single species of *Ascaris* (*Asc. Capsularia*, Rud.). They are about an inch in length, and are inclosed in a spiral form, in cysts attached to the peritoneum of the salmon. The *Capsularia halecis* figured by Zeder* exhibits a straight alimentary canal and longitudinal lines, probably nervous filaments, which resemble those lines observable under certain circumstances in the present microscopic species; but no further correspondence in internal structure can be traced between them.

The circumstance of being inclosed in cysts is common to many very differently organized genera of *Entozoa*. There are few, indeed, with the exception of those which live upon the mucous surfaces of the body, that do not, by exciting the adhesive inflammation, become inclosed within an adventitious cyst of condensed cellular substance analogous to the galls produced by the irritation of larvæ developed in the substance of a living vegetable.

The simple type of structure, which the minute animal here described exhibits, approximates it to the lower organized groups of the *Vers Intestinaux Parenchymateux* of Cuvier: and both from its locality and the constancy of the cyst inclosing it, it manifests a relation of analogy to the order *Cystica* of Rudolphi. From all the genera of this order, however, it differs in the want of the complex armature of the head and of the dilated vesicle of the tail. At first sight it might seem indicative of an annectant group, which would complete the circular arrangement of the *Entozoa*, by

* Naturgeschichte der Eingeweidewürmer, tab. i. figs. 3, 4, 5.

combining the form of the *Filariæ* of the first with some of the characteristics of the *Cysticerci* of the last, of Rudolphi's orders. Unfortunately, however, the class *Entozoa*, as it now stands, is so constituted that an animal may be referred to it without much real or available knowledge of its organization being thereby afforded: it embraces animals with the molecular and animals with the filiform conditions of the nervous system; conditions which are accompanied by different types of the digestive system, and which indicate not merely differences of class, but of primary division in the animal kingdom.

The organic form in the natural system, to which I consider the animal under consideration as being most nearly allied, is that exhibited by the lower organized *Vibriones* of Müller, and of which Ehrenberg has composed his genera *Vibrio*, *Spirillum*, and *Bacterium*: so that the present species may be regarded as affording, with the seminal *Cercariæ*, a second example from the lowest class of the animal kingdom having its *habitat* in the interior of living animal bodies. Referring it, however, provisionally, to the class of *Entozoa* of Rudolphi, in which it would indicate a new order, its generic character may be thus given:

Genus Trichina.

Animal pellucidum, filiforme, teres, posticè attenuatum: os lineare; anus nullus; tubus intestinalis genitaliaque inconspicui. (*In vesicâ externâ, celluloсâ, elasticâ, plerumque solitarium.*)

Trichina spiralis.

Trich. minutissima, spiraliter rarò flexuosè incurva; capite obtuso; collo nullo; caudâ attenuatâ obtusâ. (Vesicâ externâ elliptica, extremitatibus plerumque attenuatis elongatis.)

Hab. in *Hominis* musculis (præter involuntarios) per totum corpus diffusa, creberrima.

With respect to the case in which this singular parasite has been met with, Dr. Roupell, Physician to St. Bartholomew's Hospital, has obligingly forwarded to me the following notes:—

"Paolo Bianchi, an Italian, by trade a barometer-maker, about 50 years of age, of a sallow complexion, with black hair and eyes, was admitted under my care on the 4th of December, 1834. When admitted he was much emaciated and weak, his countenance was haggard, and his look depressed. His legs were œdematous; his urine contained albumen, was sweet, and when evaporated yielded a residue like treacle: he had pain in the back. His appetite was deranged, and his liver was felt beyond its natural limits. He had cough, but without urgent distress or hurry in the breathing or expectoration. On auscultation pectoriloquy was detected in the upper part of the lungs: his bowels were relaxed. The general treatment was to give him strength by tonic and sedative medicines, with a nutritious but not stimulating diet, and leeches were applied to the loins: for a time he appeared to gain ground, the œdema disappeared, and he gained some strength, being able to get out of bed and dress himself. But his appetite rather suddenly failed him; his diarrhœa increased; his abdomen became tense and painful; his stools passed unconsciously, and contained blood; and having received extreme unction from his priest, he died on the 29th of January, 1835, in a state of extreme debility and emaciation. There had not been observed any eruption on the skin, or any greater loss of muscular power than related to the debility caused by the disease of which he died.

"He was examined thirty-six hours after death. Tuberculous cavities were found in the upper lobes of the lungs on both sides, and specks of tubercles in both. The kidneys presented in a marked degree the change described by Dr. Bright. The liver was enlarged and fatty. The mucous membrane of the small intestines was ulcerated to a great extent."

About a fortnight after the dissection of the above subject, a second was brought into the rooms, similarly affected; respecting which Mr. Paget, who first noticed the parasites in the Italian, has favoured me with the following note:—

"The second body was that of a poor Irishwoman, who had been in Mr. Lawrence's ward for six weeks. She had died in a state of extreme emaciation, produced by a large sloughing ulcer just below the knee, by which a considerable portion of the head of the tibia had been exposed. She had had occasional severe diarrhœa, and obstinate vomiting."

As regards the seat of the *Trichinæ*, they occur in all the voluntary muscles, and in those which have been termed semi-voluntary or respiratory, as the diaphragm. My friend Mr. Wormald examined and detected them in the minute muscles of the tympanum; as many as twenty-five were lodged in the tensor tympani. I could perceive no trace of them in portions of the muscular coat of the small or large intestines; neither could I detect any in the detrusor urinæ, or in the substance of the heart.

A portion of the muscle of the first subject which was sent to me being in a state of incipient putrescence, I preserved it in

spirit of wine for three days before examining it; yet after macerating a small portion in water, and separating the cysts, the worms when pressed out continued, to my surprise, to exhibit motions, which, though languid, were sufficiently evident, tightening and dilating their coils. I suppose that, being buried in the flesh and defended by the dense exterior cyst, the spirit had not penetrated so as to act sufficiently upon them to destroy their vitality; for on adding a drop of alcohol to the expressed worms, and afterwards moistening them with water, the motions of coiling and uncoiling ceased. More languid motions than those above described were afterwards noticed by Mr. Wormald and myself in some specimens that were examined a fortnight after the death of the subject infested by them; but it is difficult whether to refer these to hygrometrical influence or to irritability.

The tenacity of life or irritability manifested by these low organized *Invertebrata*, has attracted the attention of almost every entozoologist. Rudolphi especially takes notice of the power which the *Entozoa* possess of resisting the deadly effect of ardent spirits*, and relates many other singular instances of their tenacity of life, of which not the least remarkable is that which is manifested by the *Filaria capsularia* before referred to. When the hard-frozen herrings which are sent packed up in ice to Berlin are thawed for use, these *Filariæ* or *Capsulariæ* revive and exhibit lively motions†. The same remarkable property is occasionally forced upon the notice of individuals not immediately engaged in physiological investigations. It recently happened that two medical gentlemen, having sat down to partake of a cod's head and shoulders, were disagreeably interrupted in their repast by the appearance of a large lively round worm, which on the first cut into the fish escaped therefrom, and began to coil and uncoil itself on the edge of the dish. Now this worm must have been submitted to the temperature of boiling water for at least half an hour, and the *Entozoa* would thus appear to endure with impunity extremes alike of cold and heat

With respect to the cyst of *Trichina spiralis*, I was at first inclined, from the prevailing regularity of its figure, to believe it to be the *Entozoon* itself, or a part of the *Entozoon* analogous to the dilated tail of the *Cysticerci*. Mr. Hilton, Demonstrator of Anatomy at Guy's Hospital, who appears to have first recorded this affection of the human muscles *, ascribed it to the presence of a minute species of *Cysticercus*, not being aware of the existence of the animal to which the presence of the cysts in question is owing. The difference however, between the parasitic animals under consideration and the *Cysticerci*, is at once obvious; the true *Cysticerci* are always inclosed within an adventitious cyst of cellular membrane, in which the hydatid either freely floats, or at most adheres to the inner surface by the mouth only; whereas the present cysts, besides the absence of the peculiar structure and pearly subtransparency which characterize the true hydatid, adhere to the surrounding parts by the whole of their exterior, which is covered by a cellular flocculency.

But admitting the similarity of the outer cyst of *Trichina* to the outer adventitious cyst of *Cysticercus*, it may be contended that the inner cyst is part of the organization of the inclosed worm. Its analogy to the second cyst of the genus *Anthocephalus*, within which the elongated body of that worm is seen, readily occurs, but will not hold good on a close examination. The elongated body of *Anthocephalus* is always found in organical connexion with the second cyst; and Rudolphi observes, that the point of continuity is indicated externally by a depression occasioned by the inversion of the body at that part. In the *Cysticerci* a similar appearance is frequently observed, from the inversion of the head and body within the terminal cyst; and in the *Cœnuri*, where the corresponding bladder is common to many armed heads, some of these are generally found inverted, while others are projecting externally. In all these cases, however, besides the difference of structure between the second and outer cyst, they are always perfectly distinct from each other, and readily separable. But I have never been able to effect a corresponding separation between the outer and supposed inner cyst of *Trichina*, or to demonstrate satisfactorily the existence of the latter as a distinct part: it appears to be a layer only of the external cyst, which, as is often seen in cysts of corresponding structure not formed by hydatids†, is more or less detached from the outer layer.

In almost every instance in which I have succeeded in opening the cyst with-

* Synopsis Entozoorum, p. 595.

† "In Harengas congelatas rigidas et glacie textas frigida affusa reviviscere viderim."—Hist. Entoz., tom. ii. p. 62.

* See Medical Gazette for February 2, 1833, p. 605. In the letter from Mr. Hilton to Thomas Bell, Esq. which the latter distinguished naturalist has kindly communicated to me. It is stated that three subjects, with the muscles similarly affected, have been brought to the dissecting-room at Guy's Hospital during the present season (1834-5).

† This separation of cysts alternating with a secretion of fluid, is the cause of the ***pill-box hydatid*** of Mr. Hunter, which is a distinct animal, or true *Entozoon*.

out injury to the worm within, it has been expelled entire, together with the fluid matter surrounding it, by pressure upon the cyst. Occasionally, however, a part of the worm remains adherent; but this has been accompanied with a glairy adhesive state of the fluid secretion of the cyst, and has been, I believe, dependent upon it; for when the broken pieces have been extracted and examined with a high power, both extremities have presented the same entire surface and uniform rounded appearance as in the worms which are extracted whole.

The structure and relations of the cyst, therefore, and the absence of all organical connexion between it and the contained worm, lead to the conclusion that the cyst is adventitious, foreign to the *Entozoon*, and composed of the cellular substance of the body infested, morbidly altered by the irritation of the worm.

From the tenacity of irritability manifested by the *Trichina* under circumstances so opposite to those under which it was developed, from its small size compared with the cavity of the cyst, and from the quantity of fluid in which it is immersed, it is highly probable that in its natural condition it enjoys active powers of motion. If in such movements the extremities of the worm were repeatedly pressed against the surrounding capsule, this would yield and become elongated in the directions where there was least resistance; viz. where the muscular fasciculi would most readily separate: and observation shows that it is in the direction of the fasciculi that the cysts are elongated. If the germ of a *Trichina*, or a portion of the worm separated by spontaneous fission, be deposited at the end of one of the elongated axes of the cyst, it might, in the process of development, excite the adhesive inflammation, which would then cut off the communication between the smaller cyst and that of the parent worm, while the former would be stimulated to secrete from its inner surface a serous fluid, and so go on enlarging in size, through the influence of the same causes as occasioned the formation of the cyst of the parent. Smaller cysts, of different sizes, are occasionally seen thus attached to one end of larger cysts, and I am inclined to account in this manner for their formation.

Cysts filled with opaque matter are also occasionally seen. In these the worm may have perished, or its germ, after exciting the cyst to secrete, may not have been developed, and the enlargement of the cyst may be occasioned by the accumulation of its own secretion. But these appearances are not sufficient to establish the independent vitality or existence of the cyst, in opposition to those analogies which so plainly point out its true nature and origin.

I have seen, in two pieces of the diseased muscle, groups of minute oblong vesicles, about $\frac{1}{300}$ part of an inch in length; and these may, by possibility, be germs of the *Trichina*: they are pellucid, and without internal spot or other structure.

Although the parasites which have been described are of such minute size, their number is so immense, and their distribution throughout the muscular system so extensive, that they must occasion debility from the quantity of nutriment required for their support. It is satisfactory, however, to believe, and the history of the two cases which have afforded the materials of the present communication encourages the belief, that the *Trichinæ* are productive of no other consequence than debility of the muscular system; and it may be questioned how far they can be considered as a primary cause of debility, since an enfeebled state of the vital powers is the probable condition under which they are originally developed. No painful or inconvenient symptoms were present to lead the medical attendants to suspect the condition of the muscular system which dissection afterwards disclosed; and it is not improbable that in all cases the patient himself will be unconscious of the presence of the microscopic parasites which are enjoying their vitality at his expense.

An inspection of the muscles of recently amputated limbs might afford the opportunity of examining this interesting species under peculiarly favourable circumstances; and the occurrence of two cases in the same dissecting-room within so short a period of each other, with the recollection of similar appearances being not unfrequently present in subjects dissected in the same establishment, render it highly probable that a sufficient number of observations will soon occur to elucidate this curious disease in all its relations.

It is one, and by no means the least important benefit of the present system of providing subjects for anatomical purposes, that the histories of the uncommon appearances which may present themselves can be traced, and the circumstances to which the appearances relate be accurately determined. Many an interesting pathological condition has been wholly lost to science from the want of such regulations as are now in operation; and it is not unreasonable to suppose that the unfavourable condition in which subjects were formerly for the most part obtained, may have contributed to prevent due attention being paid to the appearance which has been described, and which results from so singular and unexpected a cause.—Feb. 24, 1835.

Appendix.—At this early period of the first anatomical season which has commenced since the preceding description of the *Trichina spiralis* was written, another example has occurred in the dissecting-rooms of St. Bartholomew's Hospital of a male subject, with the muscular system similarly infested with this most interesting and remarkable parasite. Its numbers exceed, if possible, those in the cases already mentioned, every part of the voluntary muscles teeming with the minute white cysts in which the worm is contained. These cysts differ from those I have before examined, in being more opaque and gritty, so that the presence of the contained worm would not be suspected from a simple examination of their exterior, and it is probable therefore that the cysts first described in the Medical Gazette were in this state. The examples in which two worms are present in one cyst, are more common in this case than the preceding. The *Trichinæ* when extracted were more lively than I have ever seen them; and in every instance they have presented an opaque or dark-coloured spot, about one-fifth of the length of the body from the anterior extremity. On breaking across the recently extracted specimens, I have observed in several a retraction of the outer skin, leaving the substance which it envelopes protruding.

Dr. A. Farre, who has observed the same appearances in several of the *Trichinæ* of the present subject, is of opinion that the projecting substance is the alimentary canal*. I have not as yet been able to satisfy myself of its tubular structure. In one case the dark-coloured spot formed part of the protruded string. Is this body the ovary? If it be determined that there is an alimentary canal contained within, and distinct from the outer skin, then the *Trichina* would rank higher in the scale than I have placed it, and form a genus of the *Cœlelmintha*. I have not, however, in any instance seen a trace of an excretory or anal orifice.

FUNCTIONS OF TASTE AND COMMON SENSATION IN THE TONGUE.

To the Editor of the Medical Gazette.

Sir,

I should have replied at an earlier period to the polite inquiry of "A constant Reader of the Medical Gazette," relative to the condition of the olfactory function in the case of Davis, but that I was in expectation of being enabled by the delay to afford a satisfactory answer.

I have to charge myself with an undue omission in making no special inquiry, in this instance, as to the precise condition of the sense of smell, having mainly interested myself in the case with the intention of ascertaining the state of the sensibility of the tongue. On the appearance, however, of your correspondent's inquiry, I hoped to have again met with the patient; but as the man is not under medical treatment at this time, and as, from a variety of circumstances, some time may elapse before an opportunity may occur of again seeing him, I will, for the present, simply state, that Mr. Ker, whose patient he was, informs me that, from a general examination, he considered the sense of smell to be materially diminished, but not destroyed; and this on the paralysed side only: but as few trials were made with the express view of determining this point, he does not wish me to rely upon the statement as being of undoubted accuracy. If, however, on some future occasion, I should have the opportunity of determining the matter by a closer scrutiny, and if the result should differ from what has here been stated, it shall, if deemed of sufficient importance, be communicated to the profession through the medium of your excellent journal.

Whilst upon this subject, if I do not unduly trespass, I beg to offer a few remarks on the postcript appended by Mr. Bishop to the account of his very interesting case of paralysis, published in the last week's number of the Medical Gazette. In this case, because there was coincident abolition of taste and common feeling in the tongue, Mr. Bishop considers that there is a non-accordance between this fact and my views upon the same subject. Now, sir, on the two occasions that I have appeared before the profession, in connexion with the subject, I have cautiously abstained from expressing any mere *views*, but have confined myself to the facts, and the suggestion of what appeared to be the legitimate induction; and cases having been observed with most rigid minuteness, manifesting, in one instance, loss of feeling with maintenance of taste, and in the other, loss of taste with maintenance of feeling,

---

* See Dr. A. Farre's paper, in our last number but one, p. 382.—E. G.

the inference in my mind seemed to be inevitable that the two functions are distinct; and that, from analogy, we must look for a separate nervous supply. I believe it was from similar pathological facts that the probability of the compound nature of the spinal nerves was first inferred.

With all due deference to Mr. Bishop, I must suggest that because his case is not *corroborative* of mine, it is not therefore *non-accordant* with it. Cases of cutaneous paralysis of two functions in the same structure may occur without at all interfering with the doctrine of their separateness. When in the limbs, for example, we observe simultaneous abolition of sensation and voluntary motion, we do not, on that account, revert to ancient notions, but regard the paralysis as affecting the nervous structure in connexion with each of the functions; and why not adopt the same course in those cases where coincident abolition of taste and common feeling is witnessed?—I am, sir,

Your obedient servant,

DANIEL NOBLE.

Manchester, Dec. 17, 1835.

CASE OF EXTREME CONTRACTION

OF THE

AORTIC AND LEFT AURICULO-VENTRICULAR VALVES;

With its Effect upon the Arrière Circulation.

BY MARSHALL HALL, M.D. F.R.S. &c.

THE following case illustrates the effect of extreme contraction of the aortic and left auriculo-ventricular valves, upon the *arrière* circulation in the lungs, the liver, the intestines, &c., and upon the pulse. I think these have not been so well observed before, and that the case will not prove uninteresting to the readers of the Medical Gazette:—

Mr. C——, aged 63, a barrister, called on me on the 10th of September, 1835. He had returned from the Circuit, during which his friends had observed his altered appearance. I was struck with his *breathlessness*, small, indistinct pulse, pallor, thinness, &c. I appointed to see him at home.

On the next day I saw Mr. C. at his own house. There were breathlessness on the slightest exertion, augmented impulse of the heart, without either distinct second sound, or *bruit de scie*, slight *anasarca*, and slight *icterus*.

The progress of the case was rapid. The breathlessness became urgent; there was a distinct rattle over the posterior right side of the thorax; the left ventricle beat rapidly, with considerable impulse, and without distinct second sound, or bruit; there was some cough, distinct icterus, and augmented anasarca. The jugular veins were turgid; the pulse was small, irregular, indistinct.

To these symptoms hæmoptysis succeeded. The only position which could be sustained was the erect. The cough was troublesome. The breathlessness, the rattle on the right posterior side of the thorax, the rapid forcible beat of the heart without second sound or bruit, the small, indistinct pulse, the icterus, the anasarca, continued, with occasional sickness.

Gradually the cheeks became cool, the beat of the heart less forcible, the pulse less indistinct, the posture less raised, the extremities cold and clammy, and the patient sank very slowly during several days.

Examination.—The organs were examined thirty-six hours after death, on September 29th, 1835.

There was slight icterus and anasarca.

The head was not examined.

The thorax.—The *left* cavity of the pleura contained one pint of sero-sanguineous fluid.

The costal pleura was very vascular; there were no adhesions, except between two contiguous portions of the lung, and of this to the pericardium. The *right* cavity of the pleura was obliterated by adhesions.

The *trachea* and bronchia were filled by frothy bloody mucus. The bronchial tubes were dilated, and their lining membrane redder than natural.

Both lungs, but especially the right, were gorged with bloody fluid, so that only the upper portion gave the healthy crepitus on pressure between the fingers. A portion of the lower lobe of the *right* lung presented a circumscribed apoplexy, of the size of an egg. Similar but smaller apoplexies were found in the middle lobe, and in the upper lobe of the *left* lung.

The two layers of pericardium adhered by means of coagulable lymph, which admitted of being torn, and stripped of the pericardium. This membrane was vascular within; and, on its exterior surface, loaded with adeps and serum. The *heart* was considerably enlarged: the *right auricle* and ventricle were dilated and thickened; the auriculo-ventricular and pulmonary valves free from disease; the pulmonary arteries and their branches appeared enlarged: the *left auricle* was much dilated and hypertrophied; the auriculo-ventricular valve was very much thickened, of the firmness of cartilage, and admitted one finger only; the *left ventricle* was slightly enlarged and hypertrophied. The *aortic* valves were ossified and rigidly immoveable, and their orifice so contracted as not to admit the little finger.

The abdomen.—The peritoneal cavity contained no fluid. The *liver* was small, and its surface granulated. It was shewn to Mr. Kiernan, who stated that it was in the second stage of hepatic-venous congestion. The gall bladder was full of dark-coloured bile; its ducts free.

The peritonæum covering the intestines was deeply congested. The intestines themselves, from the middle of the jejunum to the rectum, were highly congested — the valvulæ conniventes being of a deep purple hue, and presenting numerous small patches of ecchymosis. The spleen, pancreas, kidney, &c. were healthy.

It is impossible that morbid appearances should follow in a more distinct order, or account more lucidly for the symptoms during life. I know of no case on record so illustrative of the effect of obstruction of the circulation, upon the *arrière* part of that circulation.

The breathlessness is accounted for by the condition of the valves of the aorta and left auriculo-ventricular valve. The smallness and indistinctness of the pulse by the former. The turgid jugulars by the impeded circulation, propagated from the lungs to the right side of the heart.

The impeded flow of the blood through the aortic and mitral valves led to *congestion* in the lungs, and this amounted to such a degree as became true "*apoplexie pulmonaire;*" in consequence of this impeded circulation in the lungs, we have congestion of the hepatic vein in its second stage; as a further consequence of hepatic-venous congestion we have congestion of the vena portæ, and of the intestine, so remarkable on the post-mortem examination.

The congested state of the liver led to the icterus, and to the hæmorrhagic state of the intestine. That of the vena cava to the anasarca.

It is impossible to imagine a *series* of phenomena more distinctly connected: the smallness of the pulse with the contracted aortic valve; the congested lung, with impeded circulation through the left side of the heart generally; the impeded flow of blood through the right side of the heart, and the turgid jugulars, with the congested lung; the congested hepatic vein, with the impeded flow of blood through the right side of the heart; the progressive, though *arrière* congestion of the vena portæ, with icterus, and of its *roots* in the intestine, with that of the hepatic vein.

IODINE—SALIVATION.

To the Editor of the Medical Gazette.

Sir,

You will perhaps consider the following note hardly worthy of a place in your columns; yet facts, in practical medicine, are always valuable, especially when they throw light upon the physiological action of remedies. In a postscript to his communication in your last number, Mr. Winslow has recorded an instance of salivation occurring during the exhibition of iodine. The same effect was produced in a patient of mine about a month ago. She had been taking the tincture of iodine for five weeks on account of a structural disease of the liver, and her dose was then about fifteen drops of Coindet's alcoholic solution three times a day. At this period it also excited headache, and slight gastric irritation.—I am, sir,

Your obedient servant,
George E. Ely, M.D.

Chatham, Dec. 16, 1835.

P.S. It is deserving of notice that mercury had been freely exhibited in the above case without producing the slightest effect upon the mouth.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

MODEST DEMANDS OF ASSURANCE COMPANIES.

MEDICAL men are surely either very great simpletons, or among the most disinterested and generous of mankind. The fact is notorious, and has long been acknowledged, that no people on earth work harder for the most inconsiderable remuneration—a remuneration bearing no proportion, (at least, compared with what accrues from other professions), to the expenses of their education and outfit. Here are no high places for ambition to soar to. When a man enters into the medical profession, his future position in life is pretty nearly determined: his path is limited; in one sense it is up-hill; and although the end and aim be not distant, it is but too often destined never to be attained.

But medical men rarely think of these things,—though surely the time is come when considerations so nearly connected with their interests ought not wholly to escape them. They see, or may if they please see, the more worldly-wise in every direction availing themselves of *their* services, and profiting by *their* singularly unwise inattention. No newly founded institution, raised for the purposes of convenient charity, ever now dreams of endowing its medical appointments with salaries; and the few old ones, that happened originally to have made a more liberal arrangement, are gradually adopting the new plan. They can find medical men enough, it appears, to fill the vacant places; and pay being no object with our professional brethren, the charitable people quietly put up their purses and say nothing.

The new Poor Law Commissioners go more boldly to work; they offer us alms; they treat us as paupers who desire to have charge of paupers; they threaten, they bully, and are often successful by these means in procuring the cheap, however ineffective, medical attendance which they require.

This, however, is less provoking after all, than the sly, selfish, conduct of assurance companies towards the profession. They have long been in the habit of worming out of medical men information of the greatest importance for their commercial schemes; and what with forms of courtesy at first, and the few applications made, it was not then worth disputing about. But their business has increased largely of late years; more numerous policies are effected at each office than ever before, notwithstanding the competition of various companies for the public favour. So far, however, is this from prompting them to the exercise of common justice, leaving generosity out of the question, that they even wax haughty; they demand that as a sort of right which they hitherto obtained from our indulgence; menaces, moreover, are plainly hinted; what we shall come to next, we can scarce conjecture. A party wishes to have his life insured—he submits to the freest and fairest examination that can be given him by the medical officers of the company—and he is willing to abide by their decision. But the managers want further security, and procuring the address of some medical acquaintance of the applicant, write to this professional man a string of interrogatories "strictly confidential:" they demand categorical replies—under the sanction of a very intelligible threat that the letter will be filed, or, in other words, that it will be preserved for future use at the respondent's peril.

Now what do we owe these people, that they should take this liberty with us? Luckily nothing; and it is perhaps the more fortunate that it is so, inasmuch as the numerous disclosures made of late regarding the transactions of some of these companies render it desirable that they should have as few official claims upon us as possible. There should be no more *courtesy* with these personages: *business* should be the sole agent to bring us in contact with them.

Some there are who have doubts whether in insurance cases the medical referee ought to be paid by the applicant, or by the office. We think these doubts ought to vanish upon putting a few simple questions. Who makes the application to us? Who has the most immediate interest in our professional testimony? Who cautions us—nay, threatens—implying that without some such strong hint we might certify falsely? Who, in short, employs us *confidentially*—meaning thereby that we should consult the interest of the office, at least as much as that of our patient? Need we append, then, another question—who ought in such circumstances to pay us for our time, trouble, and the responsibility imposed?

As a general position, therefore, we hold that the office should pay. It is idle to tell us that it is unreasonable to expect the directors to pay both their own medical officer and the referee of the person to be insured: if the information they seek be not worth a fee, they ought not to take the pains of applying for it; but we know that they think far otherwise, judging from their importunity; and it can only be attributed to a mean and selfish spirit that they seek in so ungenerous a manner to compass their ends. Nor let them plead their old-established usages: they have played at that game long enough at our expense; and if we only turn the tables on them now, as we ought to do—if we only withhold our certificates from them till we are properly treated, we shall have effected a reform in their usages and customs which in the end may be found to be perhaps the most beneficial for all parties.

It is not true, as some have asserted, that the question of fee is entirely a private affair between the applicant and his medical attendant. We deny it—not only for the reasons already stated, which prove that it is much more like a private affair between the office and the medical referee, but because, in very numerous instances, no such private relation subsists between the party about to insure and the medical man to whom he refers. How many proceed to insure their lives who do not happen to reckon in their list of friends any medical man? How many, also, who have not been visited for months, nay years, by any professional friend? How many of that equivocal class of lives (for whom a much higher premium is demanded at the offices), who cannot conscientiously be certified for without a special examination? And are professional men to act gratuitously—to devote their time and talent for nothing, to such investigations; binding themselves, into the bargain, to abide by the result? We have already said, that as a general rule, the office ought to pay: we will now add, that, in such instances as those just quoted, the applicant should pay also.

The public attention, we are glad to perceive, begins to be awakened on this subject. Some excellent letters have appeared in the newspapers, setting forth the injustice and the unreasonableness of the conductors of assurance directors in this matter; and, so far as we have been able to discover, only one feeble attempt has been made to defend the other side of the question. A writer, signing himself "M. D.," whom we strongly suspect, from the

internal evidence afforded by his letter, to be a medical officer, or employé, of one of the companies, is the solitary advocate of the course pursued by the offices. His arguments (if they deserve that name) are singularly feeble and sophistical. What he says may be reduced to three points—and very weak points they must be allowed to be. 1. In the first place he asks, "Are the directors of assurance offices blindly to send fees to all the medical men to whom they are referred?"—and he supposes the extreme case of their being referred to a St. John Long, or some person of that description. The reply to this is very simple. If the directors proceed *blindly* about their work, it is their own affair, or that of the company to which they belong. But there is no necessity for (nor, indeed, does there seem much likelihood of) this profuse sending of fees. There can be no such great difficulty, as M. D. supposes, in the directors making a selection, if they have a number to refer to. The three medical corporations which license medical practitioners throughout the country, have their printed lists, which the directors could easily procure, and thus make themselves acquainted with those to whom they might safely apply, and send the proper fee.

2. We learn from M. D.'s production, that "on all occasions when a letter of queries is sent to the medical, another is sent to the private friend, of the party. These private friends are sometimes clergymen, solicitors, barristers, bankers, merchants, &c. or other professional persons, whose time is valuable, and whose opinions are important." He adds, that these persons never get fees on such occasions; and asks, why should they not, if the medical man be entitled to payment? This is mere sophistry. In the opening clause of the quotation the writer makes a distinction between the *medical* and the *private* friend: yet in what follows he affects to consider the queries sent to both to be of the same nature. M. D. must know that this is not the case. The medical referee is applied to purely in his professional capacity: the application to him is special, confidential, official, and imperative Is the clergyman applied to *professionally?* Is the solicitor? Is the barrister? If they be—especially the latter parties, we will be bound for it, they must have their fees: they will send in their bills of costs, which *must* be paid. And so should they all be remunerated, if they be applied to in any other capacity than as private friends. The medical man, if referred to merely as such, and not professionally, or under strict injunction, we venture to say will be quite as ready as any other private friend to give all the information he can, without fee or reward.

3. The last point in M. D.'s letter is rather ludicrous. His conscience is so tender in the matter of certifying, that he cannot persuade himself to take a fee either from the applicant or the office. And why? Because, if he take a fee from the applicant, it will seem as if he (M. D.) was bribed to speak more favourably of his patient than he ought: and if he accept a fee from the office, and the patient happen to be rejected, the latter may think that he, the said M. D., was bribed to give an unfavourable report! Surely there must be something morbidly sensitive about such a conscience; perhaps not without a cause. The reputation of M. D. must, we say, be very questionable indeed, if it be so open to the suspicion of bribery. Enviable position, truly, of a medical man in the estimation of his patient, if he be supposed capable of being bribed to a dishonourable act by the paltry temptation of a fee!

If the assurance offices have no better advocate than M. D., we would recommend them to send him a fee to induce

him to hold his peace. Perhaps he would have no scruple to accept one on that score.

CHAIR OF SURGERY IN EDINBURGH.

As might have been expected, neither the Edinburgh press, nor the members of the Town Council, have suffered the ridiculous story of the *Courier*, that Mr. Liston had been offered the Chair of Surgery in "modern Athens," to pass unnoticed. This ingenious piece of puffing, which the editor of the *Lancet* echoed last week, as in duty bound, but which we then ventured to deny, on the strong presumptive evidence which we adduced, has since publicly received a contradiction the most direct, explicit, and unequivocal. Mr. Maclaren, one of the electors, took occasion, at a recent meeting of the Council, to make the observations which will be found below; and the editor of the *Scotsman*, having quoted the passage alluded to from the *Courier*, declares it to be "entirely a misrepresentation of the fact," and calls upon his London contemporary "as a matter of justice to correct his misstatement." To this appeal the *Courier* replies, with the most unblushing effrontery, that it "never assumed nor insinuated that Mr. Liston would necessarily have been elected to the Chair, had he been willing to accept it!" Pretty well this, after telling us last week that the professorship was only offered to another "as soon as it was ascertained by reference to Mr. Liston that he would not forego his prospects in London for any of the medical chairs in the University of Edinburgh." It now appears, however, from the shewing of the *Courier* itself, that the implied offer, when stripped of its editorial embellishments, is simply this:—Some indiscreet person asked Mr. Liston if he would become a candidate for the vacant professorship, and that gentleman having, during his recent visit to the North, ascertained exactly how the land lay, very wisely said he would not. Now this private transaction of two individuals has been converted into an official application to Mr. Liston, and the refusal on his part of an offer—which was never made. One little additional piece of information, of rather an amusing kind, is afforded us by the *Courier*—namely, that the article which it now attempts to back out of, with so bad a grace, was written *in consequence of information received from Mr. Liston himself.*

Proceedings of the Town Council at Edinburgh, Dec. 15, 1835.

* * *

The Lord Provost then proposed that Sir Charles be elected Professor of Surgery in the University of Edinburgh, which was seconded by Mr. Bruce, and unanimously agreed to.

Mr. Maclaren said, he had observed a paragraph in the *London Courier* relating to this subject, which was calculated to give pain to the eminent individual whom they had just elected. It stated that the feelings of the Council were nearly unanimous in favour of Mr. Liston, but that having been applied to, and having refused to leave London, it was then only the Council had thought of applying to Sir Charles Bell. Such a statement being TOTALLY UNFOUNDED, and calculated to hurt the feelings of him whom they designed to honour by their unanimity of choice, he thought it right to bring the circumstance before the Council, that the editorial article alluded to might be publicly contradicted.—*Scotsman.*

Sir Charles Bell's Letter to the Lord Provost of Edinburgh.

Brook Street, 11th Dec.

"MY LORD,—I have had the gratification of receiving your lordship's letter, and I accept the honour which you, the magistrates, and council, have conferred upon me.

"The manner in which this appointment has been conferred, and the assurances with which your lordship has accompanied the communication, lead me to anticipate the utmost harmony in our endeavour to cultivate medical science, and promote the reputation of the University.

"You place me where there is every

motive for personal exertion; but where, most of all, experience and judgment are necessary. As to the first, I trust my habits of life give you sufficient warrant. For the rest, I ground my hope of being useful on the characters of those distinguished men, many of them removed from the stage, with whom I have been united, or with whom I have been in consultation on many trying occasions. By this intercourse my opinions have been matured, and now, through your kindness, I shall use the advantages which time and circumstances have given me, so as to preserve the record of the opinions and practices of the men who have raised the profession of surgery in these kingdoms to its present acknowledged perfection.

"By this, to me, eventful change, I am led to reflect on the advantages I have possessed, in my anxiety that your lordship and the council shall not have occasion to regret the decision to which you have come.

"The unanimity of the council, and the very flattering expressions of your lordship, lessen the regret which every one must acknowledge to be natural to me in leaving a society where I have experienced uniform kindness and liberality, and in breaking the intimate and friendly relations with some of the most estimable men of our day.—I have the honour to be, my Lord, with great respect,

"Your Lordship's obliged and very humble servant,

"CHARLES BELL."

CLINICAL LECTURE

ON

FISTULÆ IN PERINEO,

Delivered at St. George's Hospital, Dec. 8, 1835,

BY SIR B. C. BRODIE.

GENTLEMEN,—You will recollect that in the case to which I drew your attention in the last lecture, one of the effects of a stricture in the urethra under which the patient laboured, was an abscess in the perineum, which had terminated in what we call *fistula in perineo*. We have another patient, labouring under the same disease, lying in the adjoining bed to the patient just referred to.

"Samuel Eldridge, 53 years of age, a coachman by occupation, was admitted on the 14th October, 1835, into Harris Ward. It appears that five months ago he had an attack of fever, attended by shivering, followed by pain, and subsequently by an abscess which burst in the perineum. He then got better, and resumed his work, although suffering much inconvenience. Three weeks before his admission the pain of the perineum became again very severe, attended with a frequent desire to make water, and great difficulty in doing so; and in this state he continued till he came into the hospital. At the time of his admission I examined the perineum, and found a large abscess in it, the skin having been extensively undermined. The abscess was immediately opened, and a great quantity of matter, putrid from the admixture of urine, was evacuated. The constitutional symptoms under which he laboured were immediately relieved, and the abscess gradually contracted. However, the greater part of the urine continued to flow, not by the natural passage, but through the opening in the perineum. On the 4th November I introduced a gum catheter, No. 9, mounted on an iron stilette, into the bladder. It did not pass without some difficulty, an obstruction being discovered in the usual seat of stricture, that is, in the membranous part of the urethra. On the 16th a gum catheter was introduced again, and allowed to remain lodged in the urethra. The retention of the catheter gave the patient no inconvenience. On the 6th December there is the following report of the case:—" He has continued to use the gum catheter; it having been removed, however, two or three times, to be replaced by larger ones. This day the gum catheter was taken away." He now makes water without pain or difficulty; the wound in the perineum is nearly healed, no more than a few drops of urine at this time passing through it when he makes water.

This man describes his case as having began with an attack of fever, attended with shivering; but you will observe that there was an abscess in the perineum, and when I passed the gum catheter there was an obstruction in the usual seat of stricture. I should conclude that there had been a stricture of the urethra going on for some time, that the patient had been making water in a small stream, but that the diminution of the stream having taken place gradually, it had escaped his observation. I conclude, also, that the attack of fever, which he describes as beginning with shivering, was the result of the abscess which this stricture had produced.

I refer to the case which was the subject of the last lecture, and I call your attention to the present case, chiefly on this account, that in each of these cases there was an abscess in the perineum communicating with the urethra, and forming what we call a *fistula in perineo*.

I am glad to have an opportunity of calling your attention to the subject of these fistulæ, because I do not think

that it is very well treated of in books; and because I am, at all events, bound to acknowledge, that in my Lectures on the Diseases of the Urinary Organs, which are published, the account of it is not so explicit as it ought to be. At least, I think I can give a better account of the disease now than I was able to do then.

A *fistula in perineo* is the result of an abscess in the perineum, communicating with the urethra at one extremity, and opening externally at the other. The whole or part of the urine flows through the fistula whenever the patient makes water; the constant irritation of the urine causes the sides of the fistula to become hard and callous; and at last, a sort of button-like projection, with the orifice of the fistula in the centre, is discovered in the perineum. The fistula differs in length and size, and the opening into the urethra differs in size also There is sometimes a single fistula, sometimes there are several; and, accordingly as the fistula is larger or smaller, accordingly as there are more or less sinuses communicating with the urethra, so does a larger or smaller quantity of urine escape through this unnatural passage whenever the patient makes water. Sometimes the urine thus voided amounts to only a few drops; sometimes it comes away in a small stream; and sometimes it comes away in so large a quantity, that that which is voided by the perineum is greater than that voided in the natural way.

A *fistula in perineo* is a very great inconvenience to the patient: he wets his dress when he makes water. The perineum is constantly teazed by the urine dribbling over it, and the passage of the urine through the fistula is often attended with a good deal of irritation and pain. A *fistula in perineo*, however, is not an evil unmixed with good. You will ask, what is the good effect that it produces? If a man has a stricture of the urethra the fistula saves him from the ill consequences of retention of urine. A spasm comes upon the stricture, and he cannot make water if there be no fistula; but if there be a fistula, when there comes a spasm on the urethra, and he cannot make water otherwise, the urine generally escapes by the fistula, and thus prevents the over-distention of the bladder, and all the ill consequences resulting from it.

A *fistula in perineo* occurs, in some cases, as a consequence of gonorrhœa; in other cases as the consequence of stricture, either independently of gonorrhœa or long after it has subsided. These two kinds of *fistulæ in perineo* require each a separate notice.

A man has a severe gonorrhæa; the urine comes away in a very small stream, because the urethra is inflamed, swollen, and contracted. At last he complains of pain in the perineum; a tumor is found there; and this state of things is frequently attended with a complete retention of urine in the bladder: at other times, however, it is attended only with an increased difficulty of making water. By and by the tumor bursts; or perhaps the surgeon feels fluctuation in it, and opens it with a lancet; pus is discharged, then the difficulty of making water subsides, and a day or two afterwards the patient finds that whenever he voids his urine a portion of it comes by the opening in the perineum.

In another case, the patient has, perhaps, never had gonorrhœa; or if he has had one, it has subsided, and left a contraction or stricture of the urethra. On some occasion he has a more than usual difficulty in making water, but not amounting to a complete retention of urine. Under these circumstances he discovers a swelling in the perineum, which increases in size, and becomes painful and tender. The tumor bursts, or the surgeon opens it; matter escapes also in this case, and afterwards a portion of the urine comes away through the opening. Where this disease is connected with gonorrhœa, there is generally only a single abscess; but when it is connected with a stricture of the urethra, there may be many abscesses formed in succession: so that a patient having a stricture of the urethra of long standing, may have *fistulæ* formed in various directions, opening into the perineum, in the middle of the scrotum, nay, even in the groin, or on the nates, or one of them, perhaps, may open into the rectum.

When the matter and urine are freely discharged through one opening, it does not often happen that any fresh abscess is formed; but when the matter and urine are not freely d scharged from the original opening, then it is probable that several abscesses may follow. This is the history, in most cases, of the formation of several *fistulæ*.

How are these *fistulæ* generated? Why should an abscess form in the perineum? Because there is a contraction of the urethra. You will observe, that whether the *fistula* is the consequence of gonorrhœa or of a stricture, some urine always flows through it afterwards, so that the abscess always communicates with the urethra.

In a great number of cases you find that the matter which is discharged is not healthy pus; it is putrid and offensive, and operates as a poison to the system; so that the patient, during the formation of the abscess, not only has repeated shiverings, but a dry brown tongue, a hot skin, a frequent pulse, and other symp-

toms of great constitutional disturbance: he labours, in fact, under all the symptoms of a severe typhus fever. Now all this is the consequence of the matter being putrid. But what is it that makes the matter putrid? It evidently arises from some admixture of urine with it.

Now if you consider all these circumstances, that in many cases the contents of the abscess bear manifest indications of urine having been mixed with them; and that in all cases, in the course of two or three days after the abscess has burst, urine begins to flow through it; I think you will be inclined to believe, with me, that an aperture must have been formed by ulceration in the mucous membrane of the urethra in the first instance. Such ulceration would allow a little urine to dribble into the cellular membrane, and the formation of an abscess would be the necessary consequence. This is the simplest way of explaining the formation of these fistulæ, and it explains every thing about them. The escape of even a single drop of urine into the cellular membrane would be sufficient to do all this mischief. I have no doubt that many abscesses about the rectum are formed in the same manner by ulceration taking place above the sphincter muscle, and a small quantity of feculent matter escapes into the neighbouring cellular membrane.

But you have been often told of the ill consequences which arise from ulceration of the urethra behind the stricture, and the consequent effusion of urine into the cellular membrane in the neighbourhood; that an effusion of urine through such an ulcerated opening produces inflammation, sloughing, and probably the death of the patient; and you will ask, why does it happen that in one case effusion of urine produces merely an abscess, which, unless it be neglected, is attended with no danger, and in other cases that it produces extensive gangrene, and afterwards death.

A *fistula in perineo*, and a general effusion of urine producing gangrene, are both, I apprehend, connected with ulceration of the urethra; but the ulceration occurs under different circumstances. If the patient be making water in a small stream, and a little ulcer forms behind the stricture, the greater part of the urine flows out by the natural passage, and it is not probable that more than a few drops will dribble into the cellular membrane through the ulcerated orifice. But if the patient has complete retention of urine, if the stricture be so contracted that not a drop of water can pass through it, and if then the urethra ulcerates behind the stricture, observe what will happen: the next time the patient tries to make water, he strains with the bladder and the abdominal muscles; the urine cannot pass by the natural passage, and it is driven by the muscles which I have mentioned, as it would be driven by a syringe, into the cellular membrane, of the perineum first, and into that of the scrotum, penis, and nates, afterwards, and a great deal of urine is extravasated. In the one case it *dribbles* into the cellular membrane, in the other it is *driven* into it; and thus I say that you will easily understand why there should be sloughing under certain circumstances, and an abscess under others.

I have known surgeons formerly who supposed that a *fistula in perineo* bore a resemblance to a *fistula in ano*, and that it was to be laid open and treated in the same manner; and I have seen this done in more than one instance. Now suppose that you were to dilate a *fistula in perineo* very extensively, what would happen? The wound would heal up to a certain point, until the *fistula* had regained the size which it had before the dilatation was made, and then the healing process would stop, and the patient be as bad as ever: in short, you gain nothing by such an operation. Consider what it is that prevents the *fistula* healing; the urine dribbling into it. How are you to make it heal up, but by preventing this dribbling of urine? Then how is this to be accomplished? Why does the urine find its way into the *fistula* in ordinary cases? It is because the urethra is contracted in front of the orifice, by which the *fistula* communicate with it. To cure the fistula, you must remove the contraction, restoring the urethra to its natural diameter.

In a case of *fistula* after gonorrhœa, this is easily accomplished. A few introductions of a bougie will probably be sufficient to dilate the urethra and make the *fistula* heal.

In cases of *fistula in perineo* connected with chronic stricture of the urethra, the treatment is just the same. All you have to do is to cure the stricture, and in nineteen cases out of twenty, by the time that it is fully dilated the *fistula* is healed. It is more easy for the urine to pass along the natural passage, if it be of its proper diameter, than it is for it to pass through the oblique passage of the *fistula*. The *fistula* has generally a kind of valvular opening into the urethra, into which the urine does not easily flow; and when you have dilated the stricture in front of the *fistula*, the urine having a free passage in that direction, ceases to flow in the other.

But there are some cases in which, in consequence of some complication—from the opening of the *fistula* being unusually large, or from there being several *fistulæ*, or from some other cause—the cure of the

fistula is not immediately consequent upon the cure of the stricture. When the *fistula* does not immediately heal, you should examine the perineum, and ascertain whether there is any cavity in it in which the urine and matter are likely to lodge. If the orifice of the *fistula* is such, that matter formed at the bottom of it does not readily escape, you must certainly dilate the orifice, or make a fresh opening somewhere else. But supposing that there is no difficulty of this description, that you have dilated the stricture to its proper diameter, and yet that the *fistula* does not heal, you may then introduce an elastic gum catheter into the bladder, and allow it to remain in the urethra, so as to draw off the urine by the catheter, and the cure of the *fistula* may perhaps take place under this mode of treatment. Yet I must acknowledge that in many cases the permanent retention of a gum catheter in the bladder does not answer the intended purpose with respect to the cure of the *fistula*. It would do so if it altogether prevented the urine flowing through it; but the fact is, that it does not in reality produce this effect: after three or four days a little urine always finds its way by the side of the gum catheter, and gets into the *fistula*, although the greater part is drawn off through the catheter. Another circumstance also takes place: the gum catheter acts like a seton, inducing inflammation and suppuration of the mucous membrane of the bladder; and some of the pus which is secreted passes through the *fistula*, and keeps it open just as much as it would be kept open by the urine itself.

In some cases I have adopted the following method:—I have made the patient draw off the water with a catheter three times daily, so that he should never make water except through the catheter, and thus that the urine should be altogether prevented from finding its way into the *fistula*. This is a better mode of treatment than the constant retention of a gum catheter in the bladder; and yet it will sometimes fail. It may be that the patient cannot manage to retain his water for eight hours, and then the introduction of a catheter three times in the twenty-four hours of course is not sufficient; and if he introduces the catheter more frequently than this, the catheter itself becomes a source of irritation, keeps up the inflammation, and produces suppuration of the urethra—in fact, operates much in the same way as a gum catheter when it is constantly retained.

In some cases, formerly, where a *fistula* was slow in healing, I tried the following method of treatment. I applied the nitrate of silver to the orifice of the *fistula* in the perineum. The orifice in general soon begun to contract, and at last healed. But it was only the orifice that healed, not the bottom of the *fistula*, and the matter always collected within, so that a fresh abscess was the consequence, bursting externally, either in the old place or somewhere else. In other cases, again, I have adopted the following plan with better success. I endeavoured to stimulate the bottom of the *fistula*, so as to make that heal, while I took measures to prevent the orifice from healing prematurely. This was effected in the following manner. I melted a little nitrate of silver in a spoon of platina, and dipped the end of a probe into it. This being repeated two or three times, the end of the probe became covered with a varnish, I may say, of the caustic. I introduced the probe, thus prepared, quite to the other extremity of the *fistula*; and when I had done this, I just touched the orifice of the fistula very slightly with the caustic potass. The effect of the nitrate of silver upon a sore surface is not so much to make a slough as it is to stimulate it to contract, granulate, and heal; whereas the effect of caustic potass is to make a slough, and prevent healing. The object which I had in view was that of making the bottom of the *fistula* heal, and preventing the orifice from healing too soon. This plan I found to be sometimes useful, and at other times to be of little benefit. Uncertain as all these modes of treatment seem to be, I have scarcely ever seen a case of *fistula in perineo* in which the patient has not ultimately got well. I do not say there are no such cases, but they are very few indeed. If all more active modes of treatment fail, tell your patient to do this: let him introduce a good-sized instrument—a metallic instrument is better than a common plaister bougie—into the bladder every morning, and not trouble himself further. If the *fistula* does not heal in three months, it may heal in six, and if not in six months, it may in the course of twelve months. I have seen a number of obstinate cases of *fistula in perineo* which, after other means have failed, have got well when the patient has had patience enough to persevere in the very simple plan of treatment which I have mentioned. I have known a patient who has voided a tea cupful of urine through a large *fistula* in the perineum every time he made water, in whom the stricture having been first fully dilated, and an instrument having been daily passed into the bladder afterwards, a perfect cure has at last taken place. Of course it is necessary that the stricture should be kept fully dilated; for if you allow it to contract, then the urine will dribble into the *fistula*, and prevent it closing.

These observations apply to the common cases of *fistula*; but there are some more rare cases, in which there is an abscess in the perineum communicating with the urethra, but not having burst externally. A patient will come to you having such an abscess in the perineum; every time he makes water the abscess swells from the urine passing into it, and when he presses upon the perineum, afterwards he squeezes urine and matter together into the urethra; and this state of things may continue for a long time. How is such an abscess as this to be treated? Will you cure it by drawing off the water? Will you cure it by dilating the stricture? Will you cure it by keeping an elastic gum catheter always in the bladder? Certainly not by any one of these methods: you must dilate the stricture; but that is only a preliminary measure. One of these blind *fistulæ* in the perineum will not be cured by simple dilatation of the stricture; and yet the cure is a very simple one. Make a free incision into the abscess, so that the fistula may open externally as well as internally; then, whenever the patient makes water, the urine, instead of lodging in the cavity, runs out at the aperture which you have made, and you convert this blind fistula into a common one, which is to be treated in one or other of the ways which I have already mentioned.

I shall next describe a case which used to perplex me very much when first I met with it, and which would perplex you when you meet with it hereafter, if I were not to explain its nature. A patient may come to you who has, perhaps, had gonorrhœa formerly, which has been followed by a stricture, perhaps a very slight one, of the urethra; or at any rate there has been a discharge from the urethra, which he calls an obstinate gleet, telling you, at the same time, that nothing will cure it. You examine the perineum, and you find in it a little tumor, not bigger apparently than a horse-bean or filbert. You can just feel it at some distance below the skin, and the patient tells you that he has had it ever since he has been the subject of this obstinate gleet, and that sometimes there is a little pain in it. Now such a little hard tumor is neither more nor less than a blind *fistula*. There is a small orifice in the urethra, and a narrow channel communicating with it, which leads into a cavity in the centre of this hard lump, and every time that the patient makes water a very small portion of urine finds its way into this cavity. In consequence of the smallness of the central cavity, and the great deposit of solid matter on its outside, the fluctuation of fluid in it is not perceptible. Such a case as this is not a very uncommon occurrence, and I have known a patient labour under this sort of hard lump in the perineum for many successive years, suffering a good deal of inconvenience from it, but not suffering excessively.

I have cured several cases of this kind by a very simple process. All that you have to do is to make an opening into the cavity in the centre of the tumor. But the cavity is very small, and how are you to find it? You may run a lancet into it, but it is very probable that it may pass on one side of the cavity; and therefore some management is necessary in performing the operation. You are to introduce the lancet a little obliquely, so that you may, as it were, almost cut the tumor in half. When you have done this, the blood and the deep-seated situation of the tumor prevent you from seeing whether you have made the opening in the central cavity or not. Introduce a piece of lint, so as to prevent the wound uniting by the first intention. Two or three days afterwards, you take out the lint; and then you ascertain whether, when the patient makes water, any comes by the opening made with the lancet. If this be the case, you may be certain that you have penetrated into the cavity, and then you have only to dilate the urethra with a proper instrument, and the patient will get well. But if you find that the urine does not flow through the artificial opening, you may proceed thus:—Introduce a piece of caustic potass through the opening you have made, down to the bottom of it, in the centre of the tumor, so as to make a slough there. A portion of the tumor will slough out, and it is twenty to one but what the cavity in the centre will be exposed, and then a cure follows. You should apply the caustic potass in such a manner that it may act on the part on which you wish it to act; defending, at the same time, the neighbouring textures, the skin especially, by washing it with vinegar.

A patient may have a *fistula* in the perineum, attended with some little contraction of the urethra, not giving him much inconvenience, so that it may not much attract his attention; and I have known individuals who have continued to be in this state for years together. Are you to allow them to remain thus merely because the *fistula* is not very troublesome? Certainly not; for you do not know to what mischief it may ultimately lead. The matter, on some occasion, may not readily escape; it may burrow, and cause sinuses in other directions, and may even do still greater mischief. Mr. Vincent and myself attended a gentleman who had suffered under a *fistula in perineo*, and which he had

neglected for a great many years. At last he observed the callosity round it grew bigger and bigger, so that it ulttimately extended to the scrotum and penis. When we were called in to see him, we found him with a malignant disease, either carcinoma or fungus hæmatodes, which hadclearly had its origin in the *fistula*, and had extended from that to the neighbouring organs. The patient ultimately died, in great distress and misery.

LECTURES ON THE DISEASES OF THE NERVOUS SYSTEM.

BY M. ANDRAL.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

INFLAMMATION OF THE SPINAL MARROW.

Chronic Encephalitis and Cerebellitis—Inflammation of Spinal Marrow—Anatomic Characters—Symptoms affecting Motion, Sensation, Digestion, Circulation, Respiration, Secretion, and the Genital Organs.

Chronic encephalitis bears a strong resemblance to the acute form of the disease: it presents nearly the same anatomical characters, but with the addition of induration. Abscesses, too, are more frequently met with than in acute encephalitis; and the pus is inclosed in a cyst, which is well formed, and has sometimes fibrous or fibro-cartilaginous parietes.

The causes are the same as those of acute encephalitis; and the disease may occur either primarily, or follow the acute form. The symptoms, also, are the same in both, except that their manifestation in the chronic is more slow and less energetic.

Chronic cerebellitis.—Chronic inflammation, and even abscesses of long standing, are frequently met with in the cerebellum, though acute inflammation there is of rare occurrence. In six or eight cases of chronic cerebellitis you will not, perhaps, find the same symptoms in any two; it is, therefore, impossible to say any thing positive on this head, and before doing so, we must wait for additional facts. It is thus that in some cases the lesion principally affects the movements of the upper or lower extremities, which may be either affected with complete paralysis, or only with a certain degree of weakness, such as to prevent the patient from being able to walk without staggering, or to keep him in perpetual danger of falling forwards. In other cases nothing is observed to be amiss with respect to motion, but there is some conspicuous change of sensation. In two cases, acute and general sensibility of the entire surface was observed; and after death the only lesion discovered was an abscess in the cerebellum. In another there was exquisite pain about the occiput; in two loss of sight was the principal phenomenon. I have already observed, in my introductory lecture, that certain affections of the cerebellum, such as tubercles, might produce blindness in children. In yet other cases, with the lesions of movement, sensation, &c. there have been nausea and vomiting throughout the whole course of the disease.

Thus it will be seen that we may have a variety of symptoms differing very much from each other, and produced separately, by the same morbid condition; and these symptoms do not as yet admit of being generalized. In proportion as the facts become multiplied, it will probably be seen that the phenomena which, indicate chronic inflammation of the cerebellum, have only appeared thus different in consequence of the disease having its seat in different parts of the organ. A diversity of symptoms, which may be readily accounted for from the numerous connections which the cerebellum has with the different points of the cerebro-spinal axis.

The treatment of chronic inflammation of the cerebellum consists in the abstraction of blood, so long as there is any symptom of re-action. We may afterwards have recourse to revulsives applied to the limbs or back of the neck; and we may also advantageously adopt the use of purgatives.

MYELITIS.

After having considered the acute and chronic inflammations of the parts within the cranium, we now proceed to inflammation of that prolongation of the cerebral mass which is contained in the vertebral canal, and which has been called the spinal marrow. *Myelitis* is the name given to this disease. Now myelitis may be either acute or chronic; but being pressed for time, I shall not separate the description of these two forms. In describing one, we shall compare its symptoms with those of the other, in such manner as to mingle their common characters, while we point out more prominently those in which they differ.

The *anatomical characters* are absolutely the same as those of encephalitis, viz. injection, softening, whether red or white, and suppuration, either infiltrated or collected into masses.

M. Velpeau found an encysted abscess near the junction of the cervical and dorsal portions of the spinal marrow. Softening and suppuration may produce an almost complete solution of continuity in

the vertebral cord, so that there may remain only a very thin fragment of nervous matter; or it may be transformed into absolute *bouillie*, preserving nothing of its natural organization.

The seat of these lesions is varied: the inflammation may affect the entire thickness of the spinal cord, or each of the sections separately, so that the anterior or posterior portions may alone be implicated,—a limitation which in some cases is both precise and well marked. Besides these distinctions, there are others: thus the inflammation may have its seat in the white substance or the grey, and, indeed, is more common in the latter. Now as this (viz. the grey matter) is situated in the centre of the cord, it happens that when it is considerably softened a vacuity is produced—a sort of central canal, more or less analogous to that which naturally exists in certain animals, and even in the human subject, up to a certain period of fœtal life. I have also seen this kind of softening in an aged person.

The *causes* are the same as those of inflammation of other parts of the nervous system, comprehending external injuries, diseases of neighbouring parts, &c. We ought also to reckon among the causes of myelitis, over action of the organ itself. M. Dupuy, of Alfort, has demonstrated that inflammation of the spinal marrow is not uncommon in animals who are compelled to perform movements too violent or too long continued, as in horses which are over-worked. The result of the observations made by the professor just named, as well as those of many other veterinary surgeons, is, that inflammation of the spinal marrow is much more common in horses than inflammation of the brain.

In speaking of the *symptoms*, we shall follow the same divisions as we have already done with regard to encephalitis.

The intellect affords us only negative results; it preserves its integrity, at least in the beginning; but the inflammation may afterwards extend to the brain, and sometimes does so very rapidly when there is but a short distance between it and the inflamed part,—as for example, when the myelitis occupies the medulla oblongata.

Motion exhibits very various disorders; and it is chiefly with respect to this function that the disease of which we speak is manifested, when it affects the anterior cords. The seat of these lesions of motion is different according to the portion of the spinal marrow which suffers, the movements of the parts which derive their nerves from the seat of the inflammation being those which are deranged.

We may also observe, then, these derangements of function in the upper or lower extremities, or in one limb only, or in all at once. The affection of motion may be displayed only in some muscles of the trunk, or it may be the diaphragm which is deranged in its action.

A general principle may here be laid down—namely, that the lesions of motion in myelitis only implicate the parts beneath the portion of the spinal marrow which is inflamed; the nerves below are no longer capable of transmitting the power of contraction. Nevertheless, M. Lullhier has cited the case of a man in which he found inflammatory softening of the cervical and upper part of the dorsal marrow, although the motion of the upper extremities had not been in the slightest degree affected. When the inflammation commences at the lower part, paraplegia only is at first observed; but in proportion as the disease advances, the muscles of the abdomen, those of the chest, upper extremities, &c. become successively implicated.

The nature of the lesions of motion differ according as the inflammation is acute or chronic: in the latter we can only observe a simple embarrassment in the movement of one or more parts. Sometimes, in place of absolute palsy, the patients only complain of weakness, more or less marked, in the state of repose; they think themselves as strong as ever, but if they be directed to grasp any thing in the hand their loss of power becomes evident. They also walk less perfectly.

In some, a slight and progressive weakness first comes on, to be followed by paralysis; sometimes it is not until two years or more after the first attack of myelitis that the paralysis becomes manifest; occasionally it is very rapid, but this is rare, for chronic inflammation of the spinal cord is much more common than acute. In some individuals cramps take place, which differ in their situation, according to the seat of the lesion; in the abdominal muscles, for example, the cavity is compressed and excruciating pain produced, which is known under the name of cramp of the intestines. In certain other cases the cramps occur in the muscles or the limbs; indeed it occasionally happens that, at first, these constitute the only symptom, to which, however, others of a more marked character soon become added. In yet other cases it is convulsions which appear, particularly in the acute form of the disease: it is such convulsive movements in acute myelitis which exactly imitate chorea, and of which M. Gendrin has related an example in the Gazette des Hôpitaux. In a few instances the myelitis has assumed a more formidable aspect, and has given rise to symptoms of

tetanus. Are we, then, to assume that every case of tetanus is produced by inflammation of the spinal cord? Certainly not; as I shall endeavour, by and by, to demonstrate. However this may be, death takes place, sooner or later, as the usual termination of this form of the disease.

Inflammation of the spinal marrow is also accompanied by various derangements of sensation; and these are predominant when the inflammation is situated in the posterior bundles. Pain is perceived at a part of the spinal marrow corresponding to the seat of the inflammation; this pain may be felt along the whole extent of the vertebral column, if the myelitis be general. It may also be aggravated by motion; but this is not constant, and principally occurs when the brain participates in the disease. Sometimes it is impossible for the patient to lie upon his back, so that he is compelled to recline on the side. It has been ascertained occasionally that pressure upon one particular spinous process corresponding to the seat of disease affects this part, notwithstanding its distance, and the interposition of the cephalo-spinal fluid; and this pressure constitutes an excellent diagnostic mark.

It has been recommended to run a sponge dipped in hot water along the spine, and it has been said that the occurrence of pain would point out the inflamed part, when the sponge arrived at it. I have tried this method, but without being satisfied of its efficacy; I think, however, that it may be useful in distinguishing this from disease of the cartilages. Although we have insisted on the manner of recognizing pain, yet its presence at a particular point of the vertebral column is not a pathognomonic sign of inflammation of the nervous cord which it contains. This pain, in fact, may depend upon an affection of the fibrous tissue, a kind of rheumatism peculiar to these parts. The diseases of the bony column may themselves give rise to such pain, or it may be of a neuralgic nature: thus rachialgia occasions pains which are often even more acute, and more intense, than those of myelitis.

Lastly, the pains may depend on inflammation of the meninges, without the spinal marrow, in any degree, participating in the disease.

Let us next turn our attention to the affections of sensation which take place at a distance from the spinal cord. Pain may be felt in the limbs, in the different parts of the trunk, or in the parietes of the abdomen. They sometimes follow the course of the large tendons; sometimes they are more vague, and have no precise or permanent seat; sometimes they are constant, and sometimes only occur at intervals. Again, these pains, which act so important a part in the history of myelitis, in certain cases assume, at their onset, the appearance of rheumatic or nervous affections, the rather as, under certain circumstances, myelitis betrays itself by pain in distant parts (of the limbs for instance), while nothing whatever is felt along the whole course of the vertebral column.

In place of that increase of sensibility which is announced by pain, there may be loss of sensation, becoming more and more general, in such sort, for instance, that the skin ceases to receive any impression even when violently pinched on any part of the surface. In other cases, some circumscribed portions of the skin preserve their sensibility unimpaired, whilst but a line beyond it is totally insensible. There may also be a simple numbness—a diminution to a greater or less extent, but not an abolition of this function. Sometimes different parts of the surface are affected with tingling, and of a sensation of cold which nothing can overcome: this is particularly remarked, at first, at the points of the fingers, but there is a tendency for the phenomena to extend after they have been limited for a longer or shorter time.

The different functions connected with nutrition are conspicuously influenced by inflammation of the spinal marrow.

With regard to *digestion*: in some cases we observe a difficulty of deglutition, evidently depending upon loss of play in the muscles of the pharynx; and this impediment to the act of swallowing may give rise to the belief that the patient is affected with an angina, which is persistent; but it may be ascertained, on post-mortem examination, that what has existed there has not been any form of angina, but an impediment to the contraction of the pharynx, arising from a lesion of the spinal cord. I have seen a case of this kind, in which there was at the same time paralysis of the tongue. On opening the body very acute inflammation was found at that part of the spinal column from which the nerves which give motion to the tongue arise. M. Fournet has also seen a case in which, after the fall of a great weight on the upper part of the vertebral canal, there suddenly supervened a paralysis, which was exactly limited to the tongue and pharynx, without the slightest sign of the same affection in any other part.

In some persons attacked with myelitis, vomiting occurs, as in inflammation of the brain. Sometimes the contraction of the lower portion of the alimentary canal be-

comes modified, and there is a degree of constipation, which frequently refuses to yield to the most active purgatives.

As to the *circulation*, if the myelitis be acute and general, there is fever, which is sometimes violent; but if the inflammation be chronic or partial, the fever is often entirely wanting. We have then, however, other remarkable symptoms: thus there may be palpitations so as to alarm the patient, and even to induce the physician to apprehend the existence of organic disease. Sometimes the most remarkable symptom is a tendency to syncope. I am at present attending a young woman who has all the signs of chronic inflammation of the spinal marrow. The slightest attempt at movement is sufficient to produce fainting, and she is becoming worse in proportion as the function of the spinal marrow is reduced.

We have, then, two sets of phenomena affecting the circulation: one belonging to the acute form of myelitis, and characterized by fever; the other connected with the chronic, and not accompanied by fever, but affecting the heart, and producing palpitations, whence, as we have just seen, may arise a constant tendency to syncope from the slightest causes.

Respiration is affected whenever that portion of the spinal cord is inflamed whence the nerves arise which supply the respiratory muscles, and also in all cases of myelitis which are of long standing; because in these the disease has a constant tendency to spread from beneath upwards. But the manner in which the respiration becomes embarrassed is not the same here as in encephalitis, where the breathing ceases, because the brain is no longer fitted to transmit through the pneumogastric nerves that influence without which respiration cannot be effected. In myelitis the brain and pneumogastric nerves are entire, the necessity of respiring being felt as usual, while the powers which are charged with the duty of inhaling and expiring the air are alone paralyzed.

Sometimes the diaphragm is paralyzed, or, at least, certain irregularities of its action take place. Among these the most remarkable is hiccup, which lasts until the death of the patient. The result of all these disorders of the respiration which accompany myelitis is, to produce asphyxia. I saw a young man who for a long time had experienced fixed pain at the upper part of the vertebral column. When he placed himself in certain attitudes, and only in certain ones, a crackling noise of a peculiar character, and which I frequently heard, occurred at the spot which was pointed out as the seat of pain; the patient was then, from time to time, attacked with a frightful paroxysm of suffocation, which lasted some minutes, after which every thing returned to its natural order. I think that in this case there is not actually an alteration of the spinal marrow, but probably a change in the superior articulation of the vertebral column, exposing the cord to be touched for a moment, and in certain positions, by a displaced vertebra. We may be led sometimes into the belief that there is disease of the lungs, or asthma, when the embarrassment of breathing arises from the cause just mentioned.

The *secretions* present some remarkable modifications. It has been said that the perspiration is always deficient; but I think that this fact has been too much generalized. The secretion of the kidneys is sometimes completely obstructed, in consequence of paralysis of the bladder; and the lower bowel sometimes participates in this inactivity, so as to produce constipation.

As to the *genital organs*, we sometimes have, in men labouring under acute myelitis, a great tendency to priapism, with pain and convulsive movements; which observation is in keeping with physiological experiments, in which, by exciting a certain part of the spinal marrow, erections, and even emissions, have been produced. On the other hand, impotence, and the impossibility of erection, have also been witnessed as the effects of myelitis. These facts would tend to prove that the genital functions are under the direct influence of the spinal cord, and that they are not exclusively governed by the cerebellum. It has been said that abortion has occurred in pregnant women becoming affected with acute myelitis, in consequence of the convulsive movements of the muscles becoming extended to the uterus; while, on the contrary, in other instances, in the period of collapse, women at their full time have been unable to expel the fœtus without assistance, in consequence of the feebleness of the uterine contractions. We thus have contrary effects according as the inflammation is acute or chronic. But beside these cases, others might be cited in which pregnant women affected with myelitis have gone their full time, and being delivered without any accident: all of which only shews how variable are the phenomena of this disease.

Let us now consider some questions relative to the *diagnosis*, and which it is very difficult to determine. Can myelitis be easily recognized by the symptoms above described? There are many circumstances which may lead us into error: thus the vertebræ may be the seat of diseases which are not perceptible from without—as certain kinds of caries; but it is true that after a time the spinal marrow is im-

plicated, and participates in the inflammation of the investing textures, whether hard or soft. Sometimes the symptoms of myelitis are assumed by another disease of the spinal marrow, in which there is only a lesion of action, without any thing being detected on post mortem examination, either in the spinal marrow itself, or its investing membranes. This lesion of action depends, then, on a deficient influx of nervous energy, or upon some other hidden cause. It is by induction alone that this research can be advanced, for there is nothing appreciable to our present physical means of investigation. Of this, however, I am certain, that I have seen in such cases a complete absence of any perceptible change of structure, in certain patients who had exhibited all the symptoms of inflammation of the spinal marrow for months together. I have seen hysterical young women seized all at once with inability to move one or more limbs, and remain paraplegic for many days. Under such circumstances disease of the spinal marrow is suspected, but a single day may dissipate all the symptoms. These different forms of palsy depend upon that ill-understood condition which constitutes hysteria, just as in certain other cases of the same disease we have blindness as one of its symptoms. It is the same with paralysis from lead; all which proves, however, not that the nervous centres are intact, but only that the organic change eludes the present state of science.

M. Esquirol has related a case in which paraplegia, without any other symptom, coincided with the presence of schirrous masses in the two anterior lobes of the brain; there was absolutely nothing about the spinal marrow. This curious case is in accordance with the hypothesis of those who hold that the motions of the inferior extremities are under the influence of the anterior lobes of the brain.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, Dec. 8, 1835.

HENRY EARLE, ESQ., F.R.S., PRESIDENT IN THE CHAIR.

ON the evening above dated, a paper by Mr. Stafford was read, and the discussion adjourned till Tuesday last. The following is a brief abstract of the paper:—

On the Treatment of Injuries received in Dissection. By R. A. STAFFORD, Esq. Surgeon to the Marylebone Infirmary.

The author commences by noticing the opinions which prevail respecting the effects of dissection wounds; some holding that a peculiar virus is introduced into the system by them, and others that the symptoms depend entirely on the nature of the part affected and the constitution of the individual. Mr. Stafford is inclined to embrace the former notion, there being many cases now on record, showing that the peculiar consequences in question are met with even where there has been no abrasion, scratch, incision, or puncture, and where the absorption of a virus is alone capable of explaining the phenomena. This will appear from some of the following cases, drawn up chiefly with a view to laying down a steady system of treatment.

I.—On the morning of the 2d of March Mr. Stafford was summoned to visit his friend Dr. S., the absorbents of whose right forefinger and forearm were inflamed and painful;—the doctor had dissected a brain the preceding day. There was a mark like a gnat-bite on the second phalanx, but no trace of any puncture. Dr. S. had gone to bed in his usual health, but was awakened by the pain in his finger at four in the morning. Pulse 90, jerking. Leeches and evaporating lotion applied; calomel and senna taken. Worse in the course of the day—nervous system affected as if under the influence of the bite of some venomous reptile. Mr. Lawrence now saw the patient: 20 more leeches were applied, and the fourth of a grain of muriate of morphia administered. The bowels acted freely, and relief was decidedly obtained from the morphia. A deep longitudinal incision was made along the finger, but no pus escaped. The morphia to be repeated as occasion might require. On the following morning the patient was rapidly sinking, when half a grain of mur. morphia was given, with almost immediate benefit. Nothing in the shape of drink but soda and seltzer water would stay on the stomach. Leeches, fomentations, and morphia continued. March 4th—Better, except that the absorbents were not less inflamed. Incision again practised on the finger, also on the palm of the hand, when pus escaped along with the blood. Great relief was also procured from subsequent longitudinal incision and the discharge of pus. The constitutional symptoms gradually gave way, and the morphia was not required in the former proportions. In short, Dr. S. was soon able to leave town, and after six weeks restored to his usual health; the finger, however, still remains stiff.

II.—The second case is that of Mr. Pierce, late assistant-apothecary of the Marylebone Infirmary. He opened the body of a woman who had died of puerperal fever, and on the following morning found himself very unwell, with headache and feverishness. In the evening he com-

plained of soreness in the axilla, but did not suspect that it could have arisen from the absorption of any virus, not being aware of having wounded himself. Leeches and fomentations were applied, but without much benefit. On the fourth day there appeared a general tumor of the side, from the third rib down to nearly the ilium; the parts tense and of a reddish blue colour; no fluctuation. The constitutional symptoms had now attained an alarming character; the patient was fast sinking; when, as a *dernier resort*, an incision nearly an inch deep, and four in length, was made in the swelling of the side. There was no pus, but the patient derived striking benefit from the quantity of blood effused, and the tension taken off the parts. Matter was discharged in a day or two, and suppuration went on thenceforward freely, if not superabundantly for the strength of the patient. But by close attention to the support of the powers of life, the symptoms soon began to amend, and in the course of about two months recovery was effected.

III.—John Moss, æt. 51, while sewing up a body, punctured the second phalanx of the fore-finger. In the course of the same day he felt extreme lassitude and headache. The finger so painful as to deprive him of sleep. The absorbents became inflamed in three distinct lines up to the elbow. Leeches applied to the finger. Fomentation to the inflamed parts. Next day lunar caustic was rubbed along the course of the inflamed absorbents—two inches in breadth. Antimonial mixture every six hours. Same night muriate of morphia administered with good effect. A puncture was made into the finger, and some sanious fluid discharged. The inflammation subsided, and the finger healed in a few days.

IV.—In this case also a puncture was received in the forefinger; the patient, æt. 69, being an attendant in a dissecting-room. The usual symptoms were manifested. Leeches, fomentations, and poultices, were applied. Lunar caustic was rubbed on, as in the preceding case, and the effect seemed to be the arrest of the inflammation. Convalescent in a few days.

V.—The same man received another wound in March last, but neglected it for three or four days, although the symptoms were severe. When examined, the absorbents were found inflamed, as were also the glands in the axilla. High fever, quick pulse, pain in the head, and delirium. Leeches, antiphlogistics, and other energetic treatment, employed; but the man sunk under excessive dyspnœa, followed by coma. At the *post-mortem*, the lungs exhibited the pathological appearances of pneumonia. The axillary glands had partially suppurated: other glands inflamed. Brain congested.

VI.—This was the case of Dr. Lee, who towards the latter end of August last, having a slight abrasion of the left forefinger, incautiously examined a uterus which he had in process of maceration. On the following day he felt pain, and observed swelling about the finger. A week, however, passed without any alarming symptoms, when suddenly shooting pain along the arm was experienced. Nervous and constitutional symptoms now set in. Leeches were applied to the fingers and palm of the hand, with fomentations. There was an obscure sensation of matter being formed: no opening was made. A splint, cold lotion, and absolute repose recommended. Under this system the finger has been gradually recovering its natural state; but still there is felt some pain in the part, nor is the swelling wholly removed.

In his general remarks on treatment, Mr. Stafford strongly recommends the use of the argentum nitratum; in the manner described in some of the preceding cases. This ought to be had recourse to immediately. The next step should be to evacuate the bowels freely. Leeches next should be abundantly applied to the swollen parts, followed by fomentations. Muriate of morphia is the best remedy for allaying the constitutional irritation. Of the expediency of general bloodletting the author entertains an unfavourable opinion, and refers to Dr. Duncan and others, whose experience in this respect accords with his own. Topical bleeding, however, he deems of the greatest consequence; and it is best effected by the repeated application of leeches. When it is ascertained that pus has been formed in the inflamed parts—and indeed whether pus be formed or not—when the patient evidently suffers from the tension of the parts, the swelling ought to be opened, and the incision wherewith this is done should be of considerable length. It is a remarkable fact that in most of the cases related by Dr. Duncan and others, where a swelling or abscess was formed without an opening being made in it, the patients did not recover; while on the contrary, where openings were made, the patients lived. Hence the propriety of free incisions even in the early stage of the swellings. In conclusion, the author suggests the proper treatment for supporting the system when the suppuration is established and the discharge abundant,—bark, wine, and nutrient diet.

The highest object of the healing art is to render itself superfluous.—Hufeland.

THE OTIC GANGLION.

We have examined a very beautiful wax preparation, just imported from Germany by Mr. Schloss, of Great Russell-street, representing the ganglion oticum of Arnold *in situ*, with the tympanum, and all the minute branches of nerves which form a communication between the ganglion and the organ of hearing. The foramen ovale is preserved entire, so that the exact situation of this famous *crux anatomica* is at once perceived. In Arnold's valuable plate (V.), among the *Icones Nervorum Capitis* (recently noticed in this journal), the ganglion is exhibited without the adjacent foramen: but nothing can be more satisfactory than the examination of both preparation and plate together. Running posteriorly from the otic ganglion we see a delicate nerve, which Arnold also claims as one of his discoveries, and calls the N. petrosus superficialis minor; beneath this another, running nearly parallel, which is called the N. tensoris tympani a ganglio otico. On the other side, running anteriorly, we observe the lingual branch, the tensor palati mollis, &c. There is also given in the preparation a view of the Gasserian ganglion, and particularly of the third branch of the fifth, together with some of the neighbouring arteries. The display altogether seems inimitable.

HENDERSON'S CUVIER.

FURTHER EXPOSURE.

To the Editor of the Medical Gazette.

Sir,

I regret to say that I can confirm the letter of your correspondent P., page 191, November 7, 1835, (which only fell into my hands this day) respecting an edition of Cuvier's Animal Kingdom now publishing by G. Henderson, 2, Old Bailey. It is true in all its particulars, and I could add to the series of *honourable* facts there stated, were it not for fear of the law of libel. I send you my address; and beg to inform P. that there are seven subscribers in Lincoln who are perfectly willing, and indeed desirous, of uniting—and union is our only resource—and as far as possible exposing the transaction. Meantime it may be as well to let P. know that we have all ceased taking the work in. It is to us matter of some amusement that Mr. G. Henderson should have fixed his abode in the *Old Bailey*. Verily he has been singularly felicitous in the choice of his neighbourhood. If P. will apply to you for my address, I will immediately correspond with him upon his sending me his.—I remain, sir,

A Late Subscriber to Henderson's Edition of Cuvier.

Lincoln, Dec. 14, 1835.

ANDRAL'S LECTURES.

A correspondent has directed our attention to the great discrepancy between M. Andral's lectures, as published in this journal, and in the Lancet. The circumstance is easily explained. Our object is to bring the opinions of the lecturer fully before our readers, in as short a space as is consistent with perfect clearness, and we therefore give the lectures, pruned of all redundancies, from reports now in course of publication in Paris, with M. Andral's express approval. As to the lecture of last week, to which our correspondent more particularly adverts, the fact is simply this: that while we began at the beginning of the Professor's discourse on *Encephalitis*, the Lancet began in the middle of it; altogether omitting the introductory observations of M. Andral, together with his account of the *causes*, the *anatomical characters*, and all the symptoms referred to the brain and nervous system; including the affections of motion, sensation, &c. Our correspondent will perceive the absurdity of supposing that M. Andral would limit the symptoms of inflammation of the brain to certain deranged functions of the stomach and lungs.

WEEKLY ACCOUNT OF BURIALS,

NOTICES.

Mr. Munk's letter next week.

A letter directed to Ruricola will be found at our publishers.

G. B.—We shall be glad to receive the illustration.

A Constant Reader, Brighton, on giving us his name and address, will probably obtain the information he desires.

Several communications reached us too late: we are obliged this week to go to press a day earlier than usual.

ERRATUM.

In Dr. Macartney's paper last week, page 452, second column, *for* "suppuration," *read* "evaporation."

Wilson & Son, Printers, 57, Skinner-St. London.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By Jon. Pereira, Esq., F.L.S.

Lecture XIV.

MOLLUSCA.

We have now arrived at the second division of animals, the *Mollusca* (from *mollis*, soft). They are distinguished by the absence of a skeleton either internal, as in the Vertebrata, or external, as in the Articulata. Externally they are protected by a soft lax skin, which envelopes them like a mantle. On the surface of, or within, this covering, there is sometimes deposited calcareous or horny matter, which constitutes the *shell*—as of the oyster and cuttle-fish. To the inner surface of the mantle are attached the motor muscles. The nervous system consists of ganglia and nerves: around the œsophagus the ganglia form a chain or collar, from whence these animals have been denominated the *cyclo-gangliata* (from *κυκλος, a circle*, and *γαγγλιον*). The circulation is double; the respiration branchial.

Orders.—Only five classes of Mollusca are now admitted—namely, *Cephalopoda*, *Pteropoda*, *Gasteropoda*, *Conchiphera*, and *Tunicata*.

Cephalopoda.

The only animal of this class which I shall notice is the *officinal cuttle-fish* (*Sepia officinalis*). The body of the sepia is lodged in a large fleshy or muscular mantle, within the substance of the dorsal portion of which is the internal shell, or *os sepiæ*. The head is furnished with two large eyes; around its base are eight long arms or feet, disposed in a radiating manner, and in the centre is the mouth, having two horny mandibles, like a parrot. Two of the feet or tentacula are much longer than the others. The internal surface of the feet is supplied with concave cups or suckers. Imbedded in the liver is a gland, secreting a dark inky fluid, which the animal discharges at pleasure through a part called the funnel.

The shell of the cuttle (*os sepiæ*) is composed principally of carbonate of lime, with a little phosphate and some animal matter. Here is John's analysis:—

	Hard Upper Portion.	Porous Part.
Carbonate (with a trace of phosphate) of lime	80	85
Non-gelatinous animal matter, soluble in water with some common salt	7	7
Gelatinous membrane, not soluble in water	9	4
Water, with a trace of magnesia	4	4
	100	100

It is not improbable that some hydriodic salt may be present.

Medicinal uses.—This os sepiæ is absorbent and antacid. It is used, when powdered, as a dentrifice.

ARTICULATA.

The third division of animals made by Cuvier, and at which we are now arrived, is that termed *Articulata*, from the articulated or jointed appearance of their bodies. In addition to this peculiarity in their external form and structure, must be added the disposition of their nervous system. This consists of a double series of ganglia, connected by nerves, and occupying the mesial line; or you may describe it as composed of two nervous cords, swelling out at intervals into ganglia. From this circumstance these beings are denominated by Dr. Grant the *Diplo-neura*. We find here no internal bony fabric around, and on which the muscles can be placed; but in its stead what has been denominated an external skeleton. This organ is, in fact, the skin, which covers, gives attachment to, and protects the muscles: it is frequently modified in its consistence, and in some instances possesses all the hardness, though not the strength, of the osseous system of the vertebrata. It is composed of several pieces, moveable on each other, from which circumstance the division has received its name.

Cuvier made four classes of them, namely, the Annelides, the Crustacea, the Arachnida, and the Insecta; and which may be thus represented in a tabular form:

			Classes.
ARTICULATA	blood red		Annelides.
	blood not red	antennæ and branchiæ	Crustacea.
		no antennæ	Arachnida.
		antennæ, no branchiæ	Insecta.

It has, however, been found necessary to add four other classes, namely, Cirrhopoda, Myriapoda, Rotifera, and Entozoa. Of these I may remark, that Cirrhopoda forms one of the molluscous classes in Cuvier's arrangement, though it agrees with the Articulata in its jointed body, and the development of its nervous system. Myriapoda formerly constituted an order of Insecta, from which they are distinguished by the number of their feet. Rotifera and Entozoa were placed among the radiate animals.

	Classes.	Examples.
Articulata, or Diplo-neura	Crustacea	Crabs.
	Arachnida	Spiders.
	Insecta	Cantharides.
	Myriapoda	Scolopendra.
	Annelides	Leeches.
	Cirrhopoda	Barnacles.
	Rotifera	Wheel animalcules.
	Entozoa	Intestinal worms.

Of these, I propose to notice first the

Annelides.

They are readily distinguished from other Articulata by their red blood, the softness of their integument, and the absence of true feet. We subdivide them into those respiring by branchiæ, and those without these organs.

		Orders.
Annelides	Branchiate	Tubicola.
		Dorsibranchia.
	Ebranchiate	Abranchia.

Some of the ebranchiate Annelides have bristle-like feet (the Chætopoda), others are without them (Apoda). In the latter division are the leeches, to which I must now direct your attention.

Hirudines, or Leeches.

History.—In commencing the description of an animal so extensively known and employed as the leech, a short historical account can hardly be uninteresting. We have, indeed, no accurate knowledge as to the exact period when these creatures either became known to, or were employed by, man; but this deficiency of information is not necessarily referrible to their discovery preceding the date of our historical documents. It is true that in the common version of our most ancient record, the Bible, we find Solomon saying, "The horse-leech hath two daughters, crying, give, give;" but critics are not

agreed as to the correctness of this translation. The word "Olukeh," or "Aluka," here interpreted "horse-leeeh," is by Bochart considered as meaning destiny, or fate, either of which terms should, according to this writer, be substituted for that of horse-leech; the daughters alluded to being Eden and Hell. But the Vulgate, Greek, and Lutheran translations, are all against his opinion. In Brandt and Ratzeburg's work you will find a very elaborate discussion of this subject, from which it appears that, in Arabic, the term *Aluka* indicates a leech, while *Aluk* signifies fate; the latter being derived from *Alaka*, to attach or hang to, because every man's fate is supposed to be appended to him, just as a leech affixes itself to the body; so that from this it appears probable the word "Olukeh," of the Old Testament, really refers to leeches. Nay, I think there is some reason for suspecting that the *Sanguisuga ægyptiaca* is the species referred to.

But admitting that these animals were known at this early period, it does not appear that they were employed in medicine: for Hippocrates makes no mention of them, though he notices other modes of drawing blood. Aristotle also is silent with regard to them. In the extracts which Cælius Aurelianus has made from the writings of Diocles, Praxagoras, Herophilus, Heraclides, Asclepiades, and other ancient physicians, who lived between the time of Hippocrates and Themison, no mention is made of the employment of leeches; a remarkable fact in favour of the opinion that they were not at this period in use. In fact, the founder of the methodic sect, Themison, is the first person in whose works we find leeches employed therapeutically. However, it does not follow that he was the first who prescribed them, though our documentary evidence fails in tracing back their use beyond him.

In the Latin and Greek languages, the animal has received its name from its sucking or drawing qualities. Thus the Greeks called it βδελλα, from βδελλω, to suck; the Romans *hirudo*, probably from *haurio*, to draw out; or *sanguisuga*, literally signifying "a bloodsucker," from *sanguis* and *sugo*. It would appear, however, that the latter of these two Latin terms is the more modern; for Pliny, in speaking of Elephants, says, "Cruciatum in potu maximum sentiunt, hausta hirudine, quam sanguisugam vulgo cæpisse appellari adverto."

Natural history.—It is most unfortunate that zoologists are not agreed as to the number either of the genera or the species of leeches. Linnæus and Cuvier admit only one genus, while de Blainville makes eleven. Linnæus, in his Swedish Fauna, included eight species, to which Müller added five or six new ones; so that Gmelin described fourteen altogether in his "Systema Naturæ." Since then other species have been added; and we find Savigny mentions eighteen, while de Blainville makes more than twenty, of some of which there are several varieties. Great confusion also exists as to the distinction of species and varieties. I may instance the common *green* and *speckled* leeches, which are regarded by some as mere varieties, by others as distinct species. In these lectures it is expected I should notice those kinds only used in medicine; I must, therefore, content myself with referring you, for an account of other species, and for some very interesting remarks on the natural history of these animals generally, to an excellent article by de Blainville, in the 47th volume of the "Dictionnaire des Sciences naturelles."

Of the Genus Sanguisuga.

The leeches commonly employed in medicine are referred, by Cuvier, to the genus *Hirudo*, which, in fact, includes leeches of all kinds; by de Blainville to *Iatrobdella* (so called from ἰατρος, a physician or surgeon, and βδελλα, a leech.) I prefer, however, adopting the term *Sanguisuga* employed by Savigny, since it is so expressive of their blood-sucking properties; for it appears that all leeches are not provided with teeth capable of perforating the skin of the vertebrata. Now this is an important fact in their natural history. In consequence of the numerous complaints addressed to the "Préfet de Police," in 1825, that of the leeches sold in Paris some would not bite, while others caused painful and obstinate wounds, he consulted the "Conseil de Salubrité," who deputed MM. Pelletier and Huzard *fils* to examine the subject; and one of the results of their investigation was, that the animal called in France the "horse-leech," and which had been particularly charged with causing painful wounds, would not, or could not, perforate the skin of the human subject; and on examining it anatomically, the teeth were found quite blunt. The reporters also state that this leech is the *Hæmopis sanguisorba* of Savigny, but de Blainville says it was the *Hæmopis nigra*.

Characters of the genus.—The following are the characters serving to distinguish the genus *Sanguisuga*. The body is elongated, the back convex, the belly flat, and the extremities somewhat narrowed, and furnished with disks or suckers. The body consists of from ninety to one hundred soft rings (the number not increasing with the age). The anterior extremity is some-

what narrower than the posterior; it is furnished with ten blackish points, called eyes, and a tri-radiate mouth with three cartilaginous jaws, each armed with numerous cutting teeth. The anus is extremely small, and is placed on the dorsal surface of the last ring.

Species.—The species are probably numerous, but I shall notice two only, *Sanguisuga officinalis* and *Sanguisuga medicinalis.* I ought, however, here to remark, that as their principal or only distinction is colour, some writers de (Blainville and Derheims, for example) regard them merely as varieties modified by the countries and places in which they are found. Without pretending to admit or deny the correctness of these opinions, I think it best, in these lectures, to follow Savigny, Brandt, Moquin-Tandon, and other excellent writers on this subject, who consider them distinct species.

Sanguisuga officinalis—This is the animal usually denominated the *green leech*, and which is called by Carena the *Hirudo provincialis*; by Risso, *Sanguisuga meridionalis.* In Germany it is called the *Hungarian leech.* It is distinguished from the other species by its unspotted olive green belly, and by the dark green back, along which are observed six longitudinal reddish stripes. Savigny mentions that six of its ten eyes are very prominent.

Varieties of this are described and figured both by Moquin-Tandon, in his "*Monographie de la Famille des Hirudinées,*" and by Brandt. Here are the characters of three: (*a*) the dorsal bands interrupted at intervals; (*b*) the dorsal bands reduced to blackish spots; (*c*) the dorsal bands united by transverse ones.

They are natives of the south of Europe, as the southern parts of France and of Germany, Hungary, &c. Those brought to England usually come from Bordeaux and Lisbon.

2. *Sanguisuga medicinalis.*—This is the kind preferred in this country, and which is usually sold in the shops. It is known by various names, such as the *true English*, or *speckled* leech. In Germany it is called *brown*, or *German* leech; and in France the *grey leech (Hirudo medicinalis grisea).* It is readily distinguished from the green leech (*Sanguisuga officinalis*) by its spotted belly, the base colour of which is yellowish-green, the spots being black. The number and size of these spots vary considerably—in some being but few, in others so numerous that they form the almost prevailing tint of the belly, the intervening spaces appearing like yellow spots. On the back are observed six longitudinal reddish or yellowish-red bands, spotted with black, and placed on an olive-green ground. The number of rings vary: ninety-three and one hundred and eight are the two extremes which have been met with.

The variations in colour are very numerous. One of the most remarkable is the *flesh-coloured leech* (*S. med. carnea*), described by Guillez, of Paris, as having the anterior half of the body flesh-coloured, while the posterior half was of the usual colour.

This leech is found native in almost all parts of Europe, but more especially in the northern parts. In England it is now rare.

Anatomy of the medicinal leech.—I propose to take a general view of the anatomy of this species of sanguisuga: I need hardly say it must be short, and, therefore, imperfect.

In the first place, let us examine the *cutaneous system.* The leech has two cutaneous layers, namely, the outer one, or epidermis, and an inner one, or corium. The first is transparent, and analogous to a serous membrane: when thrown off from the body (which is done every four or five days), it offers evident traces of the rings. The corium consists of a condensed cellular tissue, formed, according to Brandt, of globules: it shows the partitions into rings. It contains a number of globules, impregnated with a pigment, varying in its colour in different places, and which is the source of the colours presented by the surface of the animal. It is asserted that the predominant or base colour is, in part at least, owing to the colour of the soil in which the animals are found. Dr. J. R. Johnson, who published some years back a good work on this animal, says, "Mr. Baker, a man of some intelligence, residing in Glastonbury, and who for the last twenty years has been in the habit of collecting large quanties of leeches for sale, informs me that at the Black River, near Glastonbury, they are black, from the peat being of that colour; at Cook's Corner, they are of a reddish cast, from the red peat; while at Auler Moor, where, from a deficiency of peat, they penetrate the clay, they are yellow."

Connected with the cutaneous system must be noticed certain small granular bodies, found both on the belly and back of the leech, and which are particularly evident in contracted or old leeches; they give the animal a warty character; and are regarded as the mucous glands of the skin.

In the next place we may notice the *muscular system*, the most elaborate account of which, with drawings, has been given by Brandt. Firstly may be noticed the circular fibres which are observed in each ring, and are the most external of the muscular layers;

they may be called the annular muscles. 2ndly, Beneath these we have a layer composed of two sets of interlacing fibres, which are placed obliquely in reference to the circular fibres, and which cross each other at right angles. 3dly, Within these are the longitudinal fibres, which are more voluminous and developed than the others. They pass from one extremity of the animal to the other. In the posterior end, or foot, they expand circularly. 4thly, Numerous small muscles arise from the internal abdominal surface, at a little distance from the mesial line; they mount up, and are inserted in the back, between the longitudinal dorsal muscles. 5thly, More external than these, numerous small muscles arise, which are inserted between the muscles of the back. 6thly, In the posterior third of the body are five or six muscles, which arise from the back, and proceed obliquely downwards (so as to form an acute angle with the surface of the abdomen), and terminate in (7th) some longitudinal muscles running from the posterior end of the animal along the abdomen. 8thly, Fibres crossing each other are observed on the inner side of the anterior portion of the head. 9thly, Longitudinal fibres proceed to the envelopes of the jaws. Lastly, there are some annular fibres at the anterior part of the head.

The *digestive system* of leeches may, for convenience of description, be divided into the mouth, alimentary tube, anus, salivary glands, and liver. 1st, The mouth has a tri-radiate form—that is, it consists of three equi-distant lines, or rays, meeting in a centre. It is placed in the middle of the oral, or buccal disk (the superior circular edge of which is called the upper lip, the inferior one being termed the under lip.) Within this tri-radiate mouth are the three sublenticular jaws (called by some, dentiferous tubercles, by others, piercers), which are white, and of a cartilaginous appearance; but Brandt says they consist of a strong firm skin, inclosing a muscular mass. On the free, curved, sharp margin of each jaw there are about sixty small finely-pointed teeth. 2dly, The alimentary canal consists of an œsophagus, a long stomach with cæcal sacs, and an intestine. The œsophagus is a muscular tube, and commences between the inner angles of the three jaws by a roundish opening; it dilates as it approaches the stomach, but at its termination it contracts into a small circular aperture: the whole length not exceeding a quarter of an inch. The stomach occupies two-thirds of the length of the animal, and is divided into about eleven compartments or cells (regarded by some as separate stomachs.) Each of these divisions (from the second to eleventh) gives off on each side a sac (called a cæcal sac), those of the last cell being far the largest, and extending down by the side of the intestine as far as the commencement of the rectum; so that they have been compared by some (improperly as Brandt says) to the cæca of other animals. The stomach is described as possessing three coats, an outer or cellular, a muscular, and an inner coat lined with mucous glands. Posteriorly the eleventh cell of the stomach terminates by a funnel-shaped projection in the intestine. The intestine is about an inch in length; at its upper orifice is a valve, and at its lower end a sphincter: on either side of it, for the greater part of its length, is one of the sacs of the last compartment of the stomach; on its inner surface are several folds. It is divided into small and large intestine, the lower part of the latter being called a rectum. 3dly, The anus is not, as we might anticipate, in the posterior disk, but on the dorsal surface of the last ring. 4thly, Salivary organs have been described; they consist of whitish granular masses placed around the œsophagus, into which tube the common salivary duct opens. Lastly, de Blainville, Carus, and Brandt, speak of a liver. It is a brownish mass placed on the alimentary canal, the ducts opening into the stomach and intestine.

I shall conclude this account by quoting part of Dr. Johnson's directions for observing the several cells or partitions of the stomach. "Place," says he, "a leech fully gorged with blood in a saturated solution of corrosive sublimate in water. At the expiration of a week or ten days make an incision from the belly into the alimentary canal, and pick out with a needle the contents of each cell."

The *vascular system* next deserves our attention. It consists of four great pulsating vessels, giving off numerous ramifying branches; but without any heart, commonly so called. Two of these are placed laterally, a third in the median line of the dorsal surface, and a fourth on the abdominal surface. We know very little about the manner in which the blood circulates; indeed, Thomas asserts it follows no determinate order. However, it is generally supposed that the lateral tubes represent the pulmonary or branchial vessels, the dorsal the aortic, and the abdominal the venous vessel. I may add, that no globules have been found in the blood of these animals.

Where are the *respiratory organs* of the leech? If you examine the abdominal surface, you find arranged in two longitudinal rows little apertures, which have been called *stigmata, breathing holes*, or *spiraculæ*. They occur at every fifth ring, and

t, The rectum.

lead into little cavities lined by mucous membrane, and which have been called *air sacs, pulmonary vesicles, mucous bags, cryptæ*, or *lateral vesicles*, containing usually a whitish fluid. They are placed on each side of the alimentary canal, in the spaces between the cæcal sacs of the stomach, and are usually regarded as organs of respiration. Brandt, however, asserts that the respiratory function is effected solely by the skin, and that these vesicles are, in fact, receptacles for mucus secreted by a neighbouring glandular apparatus, which has a whitish appearance, and in form represents a folded intestine. This notion, however, is not new, but was held by de Blainville and Johnson.

The *nervous system* of the leech consists of two parts: *one* composed of a chain of ganglia (usually about twenty-three in number), occupying the mesial line of the abdomen, and connected by a double nervous cord. The first (and largest) is placed on the œsophagus, and by some is denominated a brain; it supplies the eyes and the neighbouring muscles. The last one supplies the posterior extremity, or foot, exclusively. The *second* part of the nervous system is that lately discovered by Brandt, and may be regarded as a kind of sympathetic system. It consists of three ganglia (connected to the brain by filaments, and supplying the jaws), and a single nerve connected to them, and running along the abdominal surface of the stomach in the mesial line.

With respect to the *organs of the senses* in the leech, I may remark, that there are no traces of an organ either for smelling or hearing. Feeling resides probably in the whole external surface of the body, but is most delicate about the mouth. The apparent fondness of leeches for certain fluids, as blood, milk, &c. would seem to show the existence of an organ of taste. The organs of vision are ten black spots, arranged in a crescent form at the anterior or cephalic extremity. Dr. Johnson says preparations of them are best made by cutting off the head of the animal, and subjecting it to pressure between strong glass plates.

The *sexual* is the last of the systems which I have to examine. Each leech is bisexual, or androgynous, but there is no power of self-impregnation (the contact of two individuals being requisite, each acting to the other in a double capacity of male and female), so that they are called imperfect hermaphrodites. It has been thought, however, by some, that under certain circumstances self-impregnation can take place. Leeches have now several times been seen *in actu coitûs*, and drawings of them in this position have been published. The male organs consist of several pairs of testicles (called by Johnson *abdominal vesicles*), two vasa deferentia, two organs analogous to vesiculæ seminales (termed by Dr. Johnson, erroneously, testes), two ejaculatory ducts, and a penis surrounded by what some have termed a prostate gland. The penis projects from the abdominal surface at about one-third distant from the anterior extremity. The female organs consist of two ovaries, two oviducts (which subsequently unite into one), and a cavity (called by some uterus), which opens by a contracted aperture (vagina), at about the 29th ring, or about five rings below the penis.

There has been a difference of opinion as to the generation of leeches, some considering them oviparous, others viviparous; while a third class of persons, desirous of reconciling these opposite opinions, believe that sometimes the one, at others the second mode of development takes place.

That leeches are essentially oviparous, admits of no doubt; and we have now an admirable account of their development by Professor Weber, in Meckel's Archiv for 1828. Brandt has given a good abstract of this, with the necessary figures, from which the following description is in great part taken. It appears that soon after copulation an unusual activity pervades the ovaries, in consequence of which some *ova* (termed by Weber *germs*, by Carus *yelks*) are separated, and pass along the oviduct to the uterus, where they stop, in order to obtain the matters necessary for their development, and their proper coats. They here become invested with a serous-like membrane, on the inner side of which is produced (either by secretion from the uterine cavity or from the membrane itself) an albuminous whitish mucus, serving in part for the nourishment of the ova, and which is regarded as a kind of *liquor amnii*. Subsequently a glutinous fluid is deposited on the outside of the serous coat. When the ova are expelled from the uterus, part of this fluid gives a coating to them, while part is expelled before and after them. But this coat seems now distended with air vesicles, and has the frothy appearance of well beaten white of egg, probably produced by the violent contraction of the uterus.

The animals usually deposit their ova (in their own native waters) in holes or moist places on the shore, usually from May to the end of September. When first expelled, they are somewhat cylindrical in their form, and have a brownish appearance. The frothy layer adheres very slightly; but after lying in the water for a quarter of an hour, the outer surface becomes somewhat hardened, forming a kind of pellicle or fine skin. After some days a portion of this frothy covering is converted into a spongy tissue (*spongy coat of the cocoon*), covering the capsule of the ova (*cocoon*) wholly or partially. In this state the cocoon has a brownish, fibrous appearance, similar to fine sponge, and varies

somewhat in its size and weight; its longest diameter being from six to twelve lines, its shortest from five to eight, and its weight from twenty-four to twenty-eight grains.

The ova or germs, which have a lenticular form, enlarge, and evince vital movements; and very soon we perceive on each a funnel-shaped tube, extending from their surface inwards, and which appears to absorb the albumen of the cocoon. The ovum goes on enlarging, and becomes somewhat elongated, and subsequently the young leech begins to be developed on the exterior part of the ovum, the aperture of the funnel being the spot where the mouth of the young leech is observed. The abdominal surface of the animal is the first, the dorsal the last, to become developed. When the young leeches have attained a considerable size, they pierce their cocoon.

Diseases of leeches.—The natural duration of the life of leeches is not easily determined; but judging from the slowness of their growth, and the length of time full-grown leeches have been preserved, we may necessarily infer that they are long-lived animals. Dr. Johnson thinks that in their native waters, if they can always meet with an abundant supply of food, they may live at least 20 years. But they are subject to several diseases, some of which are epidemic, and of a very destructive kind. Although the study of the pathology of this animal is of considerable interest in a commercial and even scientific point of view, yet it appears to me to be of minor importance in these lectures, more especially as the discussion can lead to no practical consequences; for although the diseases of leeches are probably very few, yet we have a very imperfect knowledge of their nature and treatment. I shall therefore be brief on this point. Dr. Johnson, to whose work I have had several times occasion to refer, describes the three following diseases as common to this animal:—1st. An ulcer, seated in various parts of the body, but more generally affecting the side. It destroys life in a few days. 2dly, A rigidity and narrowing of one part, whilst another portion is studded with tumors of putrid coagulated blood. 3dly, A flaccid appearance of the whole body, except the lips, which are hard, swollen, purple, and frequently bloody. These diseases are particularly prevalent during the summer months. Brostat, in the fifth volume of Brandes's Archiv describes three epidemic disorders.

The mode of procuring leeches varies. They may be caught with the hand, or by a kind of net (described by Derheims), or by the gatherers going into the ponds with naked feet, to which the leeches adhere; or by baits, especially the liver of animals. The two latter methods are objectionable,—one because it is not free from danger to the gatherers, and the other because the bait is apt to injure the health of the animal.

The modes of transport and preservation may also be noticed. Leeches are sometimes imported in bags, but more usually in small barrels, each holding about 2000, the head being made of stout canvass to admit the air. The best vessels for preserving these animals are unglazed brown pans or wooden tubs. The dealers have a notion (and possibly a correct one) that the leaden glazing is injurious. These pans should be very little more than half filled with soft water (pond, river, or rain water). This does not require changing so often as is commonly supposed. In very hot weather, or when the water has become bloody, or otherwise much discoloured, it should be changed every day or so; otherwise, in summer every four or five days or a week; in winter, once a month is believed, by large dealers, to be sufficient.

The *consumption of leeches* must be enormous. Four principal dealers in London import, on the average, 600,000 monthly, or 7,200,000 annually. In France the consumption is enormous: Fee says, "it is estimated that 3,000,000 are annually consumed in Paris; and as the population of Paris is to that of the whole of France as one is to thirty-three, it follows that, independently of exportation, 100,000,000 are consumed annually, which is equivalent to three leeches annually for each person. Now, if we estimate the average price at fifty francs per thousand, we shall have the enormous sum of five millions of francs paid for this one article of our materia medica."

The effects and uses of leeches must be deferred until our next lecture.

LECTURES ON SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

Subject continued—Forms of Phthisis illustrated by kindred Forms of Disease in external parts — Unmixed Phthisis — Mixed Phthisis — Unmixed Phthisis commonly of long duration—Sometimes lingering in one stage, and reluctant to pass beyond it—Sometimes passing quickly through all its stages, but occupying small portions of the Lungs in succession; ceasing in one and beginning in another—General and Auscultatory Signs of unmixed Phthisis.—Is Phthisis curable?

I WISH to consider some important Distinctions of Pulmonary Consumption,

grounded on Pathology, and brought to our Knowledge by Auscultation during the life of the Patient.

You have all seen an Absorbent Gland of the Neck become as hard and as large as a marble, but without pain, or heat, or discoloration, of the integuments; and hard, and indolent, and marble-like, it has remained for weeks, or months, or years.

This is a mere deposition of Tubercular Matter in the substance of the Gland.

And you have all seen an Absorbent Gland of the Neck hard and large, and without pain, or heat, or discoloration, of the Integuments for a while; but presently pain, and heat, and redness, have arisen, and what was hard has become soft, and the Integuments have become thin, and have ulcerated or burst; and Pus has been discharged, and with it a hard nucleus of Tubercular Matter; whereupon the swelling, heat, and pain, have subsided, and the parts have been restored without any remaining mark of injury, save a slight scar.

This is a Deposition of Tubercular Matter followed by Inflammation in the Substance of the Gland. But the Inflammation is restricted almost, if not altogether, to the Gland itself; and it has no sooner done its work of eliminating the Tubercular Matter, than it ceases entirely.

In like manner you have seen many Glands of the Neck remain hard and indolent, or all or several of them go on to inflame and suppurate simultaneously, or in succession. But the Inflammation and Suppuration have not continued longer, nor extended further, than was needful for the purpose of eliminating the Tubercular Matter.

There is (what is called) the *specific* Limit of a disease. By this is meant the limit proper to its local morbid action, which, for any purpose it has to accomplish, it never need to transgress.

Thus in the instances alluded to, the specific Limit of the disease was strictly preserved; for if the Tubercular Matter was to be evacuated, no less degree of inflammation could have succeeded in bringing it to the surface.

But in such Tubercular Affection of the Cervical Glands, the Disease may spread beyond its specific Limit. It may give occasion to Inflammation both more severe and more extensive than is needed for the mere Elimination of the Tubercular Matter; to Inflammation pervading the whole Neck widely and deeply, and accompanied by diffused redness, and swelling, and pain; the whole subcutaneous Cellular Structure, between the angle of the Jaw and the Clavicle, being loaded with effused Serum and Blood, and numerous apertures dripping with pus.

And all this Inflammation, with its destructive processes, is engendered and spread abroad from a mere Nucleus of Tubercular Matter in a few Absorbent Glands. Yet in another case this same Tubercular Matter lay indolent and harmless, neither the constitution nor the part feeling any apparent inconvenience from it. And in another case it created just Inflammation enough (and no more) to produce a process of ulceration which might bring it to the surface.

Behold here, upon the surface of the Body, that very Disease which in the Lungs constitutes Consumption! Behold *here* transacted before your eyes the same morbid changes and processes which (allowance being made for difference of structure) are *there* transacted within reach of the ear!

There are cases in which Pulmonary Tubercles abide long, and, perhaps, never suppurate, or at a very late period; and there are cases in which Pulmonary Tubercles excite around themselves just enough of Inflammation and Suppuration to procure their own solution or evacuation, and no more; and again, there are cases in which Pulmonary Tubercles produce and spread abroad Inflammation of every degree and every extent throughout the Lungs, beyond what is necessary to produce their own solution or evacuation. And these cases are to be distinguished from one another by Auscultation. The Distinction is of vast practical importance.

Tubercles and Vomicæ are the specific part of Pulmonary Consumption. If you do not detect one or other of these, you cannot pronounce the Patient to be consumptive. The Auscultatory Signs which denote their existence have been already enumerated.

I shall take no notice of those cases in which a few Tubercles are deposited here and there in the Lungs, without any Auscultatory Sign of their existence. We find them after death, where they were never suspected during life, and where the entire Lungs beside are perfectly healthy.

There are no Auscultatory Signs which expressly denote Tubercles. Nevertheless, I have shewn that Tubercles may be detected almost infallibly by circumstantial evidence, to which Auscultation essentially contributes. But, before they can be thus detected, Tubercles must be so largely deposited in some part of the Lungs, as to impede perceptibly the passage of air through it.

Consumption is perpetually presenting

itself to me in this form. An individual loses the complexion of health, and becomes thin; he coughs a little; but perhaps he has no notable Fever, and no constant acceleration of pulse. I auscult his chest, and find a Dulness beneath one or both clavicles, or about one or both scapulæ, and a free respiratory murmur through every other part of the Lungs. Here there is no Disease beyond Tubercles; and while they occupy the upper Lobe, the whole Lungs besides are perfectly healthy.

This form of Consumption will endure for years and years, the Auscultatory Signs continually denoting the same thing, and the patient getting neither a bit better nor a bit worse in the meantime. But he is a wretched invalid, and finds that there is something continually incapacitating him for the severer business of life.

To such a person it is a continual puzzle why he does not get well. He consults an infinite number of medical men; and it is remarkable that he gets no comfort or satisfaction from those who understand his disease the best, and the greatest comfort and satisfaction from those who understand nothing about it. Those, who know what it is, out of kindness do not tell him the Truth, and they cannot asseverate a falsehood stoutly enough to carry any weight with it; whereas those who know nothing about it affirm boldly and unhesitatingly that *it is all stomach*, really believing that the whole and sole disorder is in the stomach, and that it is within the reach of an easy cure.

Surely Auscultation is so essential a Help for arriving at the Truth in such a case, that those who are skilled in the use of it must always agree as to what the Truth is: and, indeed, there is no wonder in *their* agreement: the wonder is, that those who do not arrive at the truth should so constantly agree in adopting the same fallacy. I have been somewhat curious in my inquiries concerning this matter, and the constancy with which I have found the whole malady imputed to the Stomach has appeared to me very strange. There is, however, a circumstance in the history of these cases which gives a colour of Truth to this opinion. The state of the Bowels is very frequently such as to demand the continual use of purgative medicine; and the Cough often comes on, and with it a kind of Asthmatic Breathing, soon after Dinner; and both continue as long as the Stomach is distended with food.

In this Form of Chronic Consumption spittings of Blood are apt to take place occasionally; and, when they do, they must give fearful Intimations of Disease of the Lungs to those who are not yet assured of it by Auscultation. But I have known *them* also imputed to the Stomach.

In this form of Chronic Consumption Abscesses are liable to occur by the side of the Rectum, and to degenerate into Fistulous Sinuses.

But in this Form of Consumption Vomicæ are not postponed *indefinitely*: they at length arise, and from that time the patient sinks rapidly. Often, when a fistulous Sinus has been cured by an operation, and the long abiding discharge from it abolished, an Expectoration of Pus will occur for the first time, and never afterwards cease.

From the first formation of Vomicæ the Patient sinks rapidly. In Pulmonary Consumption, characterised by the length of its Tubercular Stage (if I may so call it), and by a seeming reluctance to pass on to the formation of Vomicæ, when, after several years, Vomicæ do ultimately take place, it is often in great numbers simultaneously, or in very quick succession; so much so, that a Lung which two or three weeks ago was, in a great part, dull to perception, and yielded no sound to the ear but Bronchial Breathing or Bronchophony, will *now* give the clearest Auscultatory Signs that it is literally riddled with Cavities; and not only so, but, if the Patient survive a little longer, that many Cavities have run together, and a Multitude become one. The same simultaneous Gurgling when the Patient breathes, and the same simultaneous Plash when he coughs, will reach the ear from half one side of the chest.

It is remarkable how to the very last the sounds are *often* properly and exclusively those of *Phthisical* Disease, or rather those which it belongs to the essential conditions of Phthisical Disease in the Lungs alone to produce, and *those sounds only*. There are Cavernous Breathing, or Gurgling Breathing and Gurgling Cough, or Pectoriloquy; and in whatever parts of the Lungs you have not these, if you have any sound at all, it is the Vesicular Murmur of Health.

Nothing is more common, upon Dissection, than to find the Lungs most largely beset with Tubercles and Vomicæ; and at the same time every part of them, which a Tubercle or a Vomica does not absolutely occupy, altogether healthy.

Such is one Form of Pulmonary Consumption; and it would seem to be, in many striking circumstances, distinguishable from others. I may fairly wish that I had a less accurate knowledge of it; for that knowledge first came to me from observing its symptoms in two of my most valued Friends, and from watching in them, year after year, the sure but hesitating approaches of Death.

But Consumption is perpetually presenting itself to me under a different character. The Patient will live as long as he whose Disease is slow to advance beyond the stage of mere Tubercles. His condition, however, is different; and that condition varies more from time to time: he will spit for a while considerable quantities of Pus, and then cease from Expectorating altogether. He will suffer Hectic Fever, and then throw it off, and then suffer it again; lose his Flesh, and recover it, and then lose it again. Here, if you auscult the chest, you will find Cavernous Respiration or Pectoriloquy, a Gurgling Respiration or a Gurgling Cough at the Apex of one or both Lungs, and at every other part a clear vesicular Murmur.

These are the cases in which Pulmonary Tubercles excite around themselves just enough of Inflammation and Suppuration to procure their own solution or evacuation, and no more. The Phthisical Disease is carrying on its own specific processes within its own specific limits. It is depositing Tubercular Matter, and then maturating, and softening, and evacuating it; and the result is the formation of a Vomica. But, except in the seat of the Vomica, the whole Lung still remains healthy.

A very dear Friend of my own was twelve years dying of Consumption; and another Individual was twenty. They had an almost constant Expectoration, and Hectic Fever, coming and going during twelve and twenty years; but they died before the days of Auscultation, and, therefore, the exact Condition of the Lungs at different periods during the progress of their Disease was not known. I know a man, now living, who occasionally spits Blood and Pus, and who has occasionally spit Blood and Pus during the last twenty years. At various times during the last four years Auscultation has discovered a Vomica or Vomicæ at the Apex of one Lung, but, withal, a satisfactory Vesicular Murmur in other parts. This Individual, in what regards eating and drinking, has lived a life of abstinence, but a life of great toil in what regards exertion of body and mind. Sometimes his Friends are full of apprehension about him; his Hectic Fever, his Emaciation, his Cough and Expectoration, seem preludes to the worst event; but again he rallies, and his mind and his body recover, or seem to recover, their wonted powers.

But in this Form of Pulmonary Consumption, a time arrives at which there is no more resumption of the appearance or reality of Health, no more pausing between (as it would seem) the formation of one Vomica and another. The Hectic, the Cough, the Expectoration, continue; the Emaciation increases; the Strength declines; and Auscultation has no longer to seek the Gargouillement, the Cavernous Breathing, or the Pectoriloquy, in one spot, but finds them at all times any where between the Clavicle and the Mamma, or any where about the Scapula on one or both sides.

Here, too, however, it is remarkable, as in the other form of Consumption, that the Vesicular Murmur of Health is *often* heard to the last in all parts of the Lungs besides; and, upon dissection, that all parts are often found Healthy which a Tubercle or Vomica does not actually occupy.

The difference between the present form of Pulmonary Consumption and the former is this—that the former lingered long in the Tubercular Stage, Tubercular Matter continuing to be deposited year after year, but no Vomica occurring, until, at a very advanced period, many were formed simultaneously, or in quick succession, and hurried on the patient to Dissolution with great rapidity; whereas in the present, the Vomica, and Vomica only, is the Object recognised by Auscultation. Tubercle must precede it. But the Tubercle is hardly deposited before the process of softening and evacuating it arises, and a Vomica is the result. Thus Tubercle is formed after Tubercle (as it should seem), with some interval of time between, and Vomica after Vomica; but the Vomica is the more abiding Morbid Condition.

These are genuine and unmixed forms of Pulmonary Consumption; and I have dwelt upon them because they are so, and because I am indebted for my Knowledge of them, as distinguished from others, to Auscultation.

Of these two genuine and unmixed forms of Phthisis, the first is unquestionably the most hopeless. Where Tubercles are largely deposited, and continue still to increase, and do not pass on to Vomica, there is never the smallest attempt towards a restoration to Health—not even of a temporary or apparent Restoration.

But where Tubercles arise one by one, or a few together, and this one or these few pass rapidly into the state of Vomicæ,—and where a pause ensues between each successive Formation of Tubercles and Vomicæ,—then, during that pause, there is the opportunity for the powers of reparation to come into action; and, in truth, there often does arise a manifest endeavour after Health,—an endeavour which succeeds so far as to recover some of its conditions, and to suspend the disease: and then, during that pause, there is always the Hope (for where Disease is suspended and Health is partly

recovered, we cannot help hoping) that Reparation may be complete, and the Disease abolished altogether.

But can this be? Does Consumption *ever* admit of cure? If ever, it must surely be when it occurs in that form which we are now considering. Let us, therefore, now give a few moments to this interesting question.

A Vomica certainly admits of reparation so far as not to be a Vomica any longer, but not so far as to leave behind it no trace within the Lungs. It leaves behind it a scar—that is, the disease ceases in the part, but the part is not restored to the exact condition in which it was before the disease began.

In examining by Dissection the bodies of those who die of Pulmonary Consumption, among many existing Vomicæ we occasionally find the Traces of a Vomica healed. At the apex of the Lung we find an indentation, and descending from it, for half an inch or an inch, a thick perpendicular line of tough ligamentous substance. Sometimes this substance, by being pulled asunder, is discovered to contain the remains of a cavity, and sometimes not.

But what imports this Reparation of a single Vomica, if so many besides still exist? A Reparation of a twentieth part of the existing disease cannot be called a cure.

But in those who have not died of any pulmonary symptoms, and who were never known during their lives to have had any symptoms apparently phthisical, the same evidences have been found after death of what once was a Vomica, but no existing Vomicæ together with it.

This is a cure, or tantamount to a cure. It is as much a cure as when a single Scrofulous Cervical Gland goes on to suppuration and heals with a Scar. A single Vomica, you may say, is as much of the essence of Consumption as a hundred; and if the morbid structure (no matter how small) in which the disease essentially consists be repaired, the disease is cured—that is, the Consumption is cured. But it was a Consumption which nobody knew to exist.

Now all this may be very fine reasoning; but it does not meet the plain meaning of the inquiry whether Consumption be curable. It is not proof enough to common sense of its being so, that a few isolated Vomicæ, which give no sign of their existence, should have undergone Reparation.

All the world is asking us whether Consumption be curable? Indeed all the world is interested in the question: for there is hardly a family into which consumption, sooner or later, does not enter; and when a man makes the inquiry (as it were) speculatively, or indifferently, he has most likely a real practical interest in it at home. He says, "Is Consumption a curable disease?" But he *would* say, "I have a wife or a child, a brother or a sister, who is decidedly consumptive; is there the least possible hope left me that they can recover?"

To the question proposed with *such intent*, it is a mockery to answer "consumption *is* a curable disease"; for that its entire process from beginning to end—its formation, progress, cure—may be *secretly* transacted within the body without our knowing or suspecting any thing about it.

If you ask me, as a Physician, whether I have ever had experience of a perfect and satisfactory Recovery taking place, where there have been all the best known *popular* symptoms of Phthisis decidedly marked—symptoms which (*as far as they go*) no Physician could possibly say were not those of Phthisis—I answer "often."

But if you ask me whether I have ever had experience of the like perfect and satisfactory recovery where there were all these popular symptoms, and, withal, the conditions proper to Phthisis, ascertained by competent observers to exist beyond a doubt within the lungs—I answer "hitherto never."

What shall we say then? How shall we answer the popular question in the popular sense, and still answer it truly? We *cannot* say that Consumption is curable; but we *can* say (and truly) that there are cases of *imputed* consumption which put on such an aspect of the *real* disease that they are with difficulty distinguished from it, yet have not its essence. These are all within the possibility of cure.

We *can* say that there are cases essentially phthisical, in which the disease is so lingering in a particular stage, that many years are often required to bring it to its fatal termination. The Decline is gradual almost imperceptible, but sure. These fall within my first description.

Again, we can say that there are cases essentially phthisical (and these fall under my second description) in which the Disease accomplishes its course, as it were, by parts and parcels; many times apparently beginning, and many times apparently ending, but always (as far as I see) beginning again: a year two of Disease, a year or two of Health, then a year or two of Disease again. Yet, upon these terms, I have known those who have passed neither a short, nor a useless, nor an unhappy life. I have known those who have so gathered up the fragments of their broken health as to make them serve for high and useful purposes, and put to shame the fewer and smaller performances of stronger men.

OBSERVATIONS

ON

THE VENEREAL PRACTICE OF BERLIN.

By Alexander Ure, M.D., M.R.C.S.

Late House-Surgeon to the Royal Infirmary at Glasgow.

During the year 1834 I enjoyed a good opportunity of studying the forms of venereal affection most prevalent in Berlin, of ascertaining whether the therapeutic principles which governed their treatment were essentially different from those adopted in other countries, and of determining by minute observation the advantages or disadvantages resulting from their application in practice.

It is only in large towns, the seats of luxury and vice, that adequate scope is afforded for tracing the origin, progress, and termination, of this class of distempers, because a great number of individuals labouring under its effects in various forms are congregated in their hospitals. The incipient phenomena which afford the best clue to the more advanced symptoms can nowhere be investigated with so much facility as in Paris and Berlin, where the civil authorities carefully watch over the health of the females who live by prostitution, and thus detect the infection in forms rarely seen in the public practice of London.

The police, in their efforts to restrain one of the most offensive results of dissolute manners, compel these unhappy persons to undergo a strict examination once or twice every week, before a competent medical tribunal. Every female who is unsound, or who presents even suspicious symptoms, is sent to the public hospital, where she is very carefully examined; and if the judgment of the inspecting surgeon be confirmed, she is detained as an in-door patient, and not dismissed until perfectly cured.

In this way it is supposed that the disease, taken at the very commencement, if it cannot be speedily stopped, is at all events prevented from carrying its ravages to such an extent as to undermine the constitution. Thus also the chances of its being widely disseminated in society are greatly diminished.

Many intelligent observers have doubted whether such legislative enactments, as usually enforced, have any real utility. It is well known that, from hasty examination, the inspector has in numberless instances overlooked morbid phenomena, and thereby sanctioned by his certificates the circulation of disease. It would, moreover, appear from the recent researches of Ricord and Cullerier, that it is often difficult, sometimes impossible, to determine at once whether the affection be truly syphilitic or not.

In the great public hospital, the Charité of Berlin, four wards are allotted exclusively to the reception of persons labouring under symptoms of recent venereal affection. Such as are suffering constitutionally from inveterate syphilis are consigned to the care of the ordinary surgeon, in the *äussere station*, or common surgical wards. Of the above wards, two are set apart for males, and two for females. To the latter are admitted not merely the recognized women of the town, but females of every description, as servants, labourers' wives, &c. in whom any signs of recent contamination are to be detected.

The male wards are light, roomy, and well aired, containing forty beds; the female wards are still more capacious. Both sets are usually filled, especially the latter. Adjoining each is a small apartment, in which the attending physician, or, in his absence, the *stabsarzt*, makes his daily inspections of such as are able to go about. The others are visited in bed. Every patient undergoes a minute examination twice, at least, in the week; but the more important and urgent cases receive daily attendance*.

On the days appointed for examination, the persons found to be free from disease are dismissed by the physician. Under such a regime, the cures are rapid; so that the average number selected for dismission on these occasions, amounts to ten; which is about one-ninth part of the whole inmates. If, as often happens, the sole cause of their being sent to the hospital is some slight abrasion, a few days will suffice for treating it. If, on the contrary, from constitutional or other causes, over which medicine has no immediate control, the disease may assume an obstinate character, and resist the usual remedies, or, after having vanished for

* I feel bound to acknowledge the liberal permission afforded me by Professor Kluge to visit these private wards, as also the readiness shewn on every occasion, by the medical assistant, Dr. Kuhk, in facilitating my inquiries as to the nature and treatment of the affections in question.

a time, it may reappear, months will often pass over before it seems quite extinct. This is frequently the case with condylomata. I saw a young female confined during a period of six months, in consequence of excrescences occurring from time to time on parts which a day or two before had been apparently sound.

The average period of each cure, deducted from the comparison of a great many cases, was twenty-one days.

The recent forms of genital disease which usually occur in the Berlin Hospital, according to my own observations, are ulcers of the genitals, and condylomata*.

It would be no easy task to decide which of the two is of most frequent occurrence. Both are sometimes met with in the same individual, but such a complication is comparatively rare.

The sores are classed into the syphilitic and non-syphilitic. The former are round, or oval, deeply excavated ulcers, with hardened edges, lardaceous or dirty-brown surface, most commonly found in men, upon the corona glandis or inner folds of the prepuce; always attended with a loss of substance. They are usually designated the Hunterian chancre. The non-syphilitic comprise every description of sore destitute of the characters assigned to the preceding. They are for the most part superficial; their centre is of yellowish tinge, dotted with minute red points of granulation on the same plane with the margins of the ulcer, which are of the natural colour of the surrounding integuments, or else exhibit a pale-red hue. These appearances are by no means constant; for here, as in every other part of the body, is the aspect of a sore liable to modification from external as well as internal causes. The state of the abdominal circulation, for instance, exerts a considerable influence in this respect, as every person engaged in extensive practice must have remarked the livid red hue which they assume during the latter months of pregnancy,—an appearance which, viewed inconsiderately, might lead to fallacy in diagnosis, by inducing the observer to assign inflammation or irritation as the cause of what was merely an effect of impeded circulation in the sanguiferous trunks.

* Gonorrhœa is hardly recognized as a ground of reception.

Simple sores are frequently met with at the introitus vaginæ, from violent laceration of one or more of the carunculæ myrtiformes at their base. They are easily recognized by the partially detached, often ulcerated caruncula, which remains, commonly connected by a slender filamentous pedicle at one extremity of the ulceration.

Condylomata are those red warty-looking excrescences, of various form and consistence, with regard to whose origin and treatment great diversity of opinion prevails. They are commonly met with implanted on the surface of the genitals and neighbouring integuments, but they have been observed on the under surface and sides of the tongue, on the tonsils, on the eyelids, about the mouth and chin, and in the meatus narium and auditorius.

These excrescences are in Berlin recognized under two forms: the *marisca*, or soft condyloma, technically called *condyloma acuminatum*, from its pointed shape; and the broad hard condyloma, or *condyloma latum*, from its flatness. This distinction, derived from their organization, is of importance, both in reference to the prognosis and the treatment.

The common localities of the condyloma acuminatum are the corona glandis, the glans, the inner folds of the prepuce, the orifice of the urethra, and in some rare instances within the canal, the vagina, the os tincæ, both sides of the nymphæ, and the internal surface of the labia.

Their primary form is that of minute eminences supplied by delicate vessels, into which the colouring matter of the blood does not appear to enter. A superficial glance can discover only faint streaks upon reddish areolæ, resembling the efflorescence of certain exanthemata, of which it is not easy to convey a clear description. On closer examination, these paler coloured patches seem to consist of *phlyctenular* groups, from which a little whitish mucus exudes. In the course of a few days small insulated prominences, faintly perceptible by the naked eye, may be detected by gliding the point of the finger over the surface of the membrane. These becoming farther developed, progressively augment in volume, and ultimately, by a process of accretion, form a homogeneous mass, attached to the surface by a narrow pedicle, or reposing on

a broad sessile base. Their colour is a bright coral red; they are translucent at the edges. On minute dissection, they are observed to be not superimposed upon the mucous membrane, but to have sprung up through the epidermis or epithelium. They are endued with a delicate membranous envelope proper to themselves, of a smooth glistening aspect, constantly moistened with a thin whitish secretion. Their internal structure is composed of a soft cellular parenchyma, through which the vessels which organize and nourish them may be seen to ramify. To the touch they convey the sensation analogous to what is communicated by gelatinous polypi. They possess a high degree of sensibility, and bleed on being irritated with the finger or any pointed instrument. A writer of great ability defines them to be — "des groupes de vaisseaux lies par du tissu cellulaire, au lieu d'etre epanouis en membranes, ces vaisseaux sont rassemblés en paquets et constituent des arborisations verticales *."

In considering their structure it occurs to me that they might with propriety be termed endermic condylomata.

After these vegetations have subsisted for some time, their surface becomes irregular and rugose, from the presence of numerous elevated points and longitudinal furrows, and they assume the most anomalous shapes. Whence the older pathologists, whose attention was more directed to the form than the substance, have, in their parade of nomenclature, designated them under various appellations, such as ficus, morum, fragum, crista, thymus, porrum, myrmecium.

In some instances their rapidity of growth is truly astonishing. Cullerier has mentioned the following example of a man, in whom, eight days after impure sexual intercourse, a small pustule made its appearance on the left side of the gland. This had been scratched away; but was soon after replaced by a vegetation, followed by several others, which coalesced; and in the course of five months attained the size of a hen's egg, occupying the prepuce and gland†. In their early stage care must be taken not to mistake for them the sebaceous glands, which are often seen enlarged and of a bright red colour, scattered over the labia and vaginal orifice, particularly in females of a blond complexion: and the undue development of which, under the circumstances, Ritgen* conceives to denote a general morbid condition of the genital organs. These muciparous glands always present a minute central dark point, indicating the orifice of the duct, and want the areola which encircle the condyloma, and furnishes perfect diagnostic marks.

The high sensibility with which the condylomata are endowed will serve as an obvious means of discriminating them from the small insulated carunculæ at the intreitus vaginæ, which latter are not so tender as to prevent their being freely touched.

* In an ingenious paper, recently published, on the secreting papillæ of the vagina and uterus, it is endeavoured to be proved that these little prominences of the mucous membrane may be the seat of congestion, inflammation, suppuration, ulceration, nay even gangrene; and although their development may be compatible with a healthy condition of these parts, it may also indicate a state of morbid congestion.—*Ritgen on the Secreting Papillæ of the Mucous Membrane of the Vagina and Uterus in Neue Zeitschrift f. Geburtskunde*, Bd. II. H. 1, p. 1—15.

ON ELECTRICITY AND DR PHILIP'S VIEWS OF THE NERVOUS INFLUENCE.

By C. J. B. Williams, M.D. F.R.S. &c.

To the Editor of the Medical Gazette.

Sir,

I am reluctant to trespass again on the attention of your readers; for they must have perceived that, whatever impressions it may have produced in the minds of others, the discussion between Dr. W. Philip and myself has led to no new convictions in the minds of the disputants†. I expect no better success in this respect from the present communication; and my chief reason for troubling you with it is, to guard those who may not be well acquainted with the subject from being misled by some of

† I have delayed these observations until after the appearance of Dr. Philip's last letter, lest I should again incur the charge of having misunderstood him. Of that charge I would only remark that my reply was addressed to the precise expressions contained in Dr. Philip's letters. In his subsequent explanations he has modified those expressions.

Dr. Philip's statements of fact, in which he will find himself to be in error.

Dr. Philip says, in his last letter but one, p. 396, that *the electricity of electric animals produces no effect on the electrometer*. In Dr. J. Davy's paper on the torpedo, published in the Philosophical Transactions of last year, it will be seen that the electricity of the torpedo *not only affected the electrometer, but was transmitted through wires, magnetised needles, decomposed iodide of potassium;* and produced all the characteristic effects of the electric current except the spark; which it could not do for the obvious reason, that the structure of the animal prevents the application of those means of insulation which are necessary to give the current intensity enough to pass through non-conductors as a spark*.

Even before these researches of Dr. Davy, the nature of the electricity of the gymnotus and torpedo was pretty apparent, in its being transmitted by metallic wires, as well as in the characteristic shock which it produced in other animals. This form of electricity is, therefore, established on grounds equal to those of magnetic electricity, and far more ample than the slender points on which the analogy between voltaic electricity and the nervous influence at present stands. I may here add, that although the phenomena of electric animals may be adduced as an analogical argument to prove that animals can produce electricity; yet, the extraordinary specific apparatus which these animals possess appropriates to them the peculiar function which it is known to bear, and destroys their analogy with other animals in which no trace of such organs can be found.

Another error which I think it necessary to correct is contained in the following passage: Dr. Philip says, "Carbon and oxygen will not combine by mere juxta-position either in the living blood or in the laboratory of the chemist. In the latter they may be made to combine by the electric power; in the former, as appears from facts I have stated, by the nervous influence; so that here also we see electricity possessing the same property as that influence."

Now these assertions, as far as they relate to the living blood and the nervous influence, constitute a *petitio principii;* and as far as they refer to the laboratory of the chemist and electricity, they are contrary to fact. Carbon and oxygen *will unite by mere juxta-position* in the laboratory of the chemist,—witness the innumerable cases in which dead organic matters, both animal and vegetable, convert the oxygen of the air into carbonic acid. Several instances of this are mentioned in my paper on respiration and animal heat; and we cannot take a more appropriate example than the blood itself; which, for days and weeks, even when it has become putrid, will still continue to absorb oxygen and evolve carbonic acid. Here, then, if the union of carbon and oxygen depend on electricity at all, it is, as I have before said, on the intrinsic electricities of the uniting matters, and not on any from without. Further, electricity, *quasi* electricity, shows no power of making carbon and oxygen unite where they otherwise would not unite. An electric current will not cause charcoal to unite with oxygen, unless the current develope *heat sufficient to burn* the charcoal at its usual point of combustion. Heat, not electricity, is here the immediate agent; and it exalts the chemical affinities in the usual way, in a manner that cannot find a parallel in liquid blood.

The passages corrected in the preceding remarks are the only parts of Dr. Philip's reply which appeared really to affect the arguments of my last communication, to which I again refer for a statement of the true position of the questions at issue. I shall now only say a few words on the leading facts on which Dr. Philip's views are founded, and to which he complains I have made no reply.

1. When the eighth nerves are cut in the neck, and the divided ends kept asunder, the secretion of the gastric juice is generally suspended*. When simply divided, with little separation or loss of substance, this effect is not produced. Hence Dr. Philip concludes that the influence conveyed by these

* Mr. Faraday is endeavouring, with the aid of the government authorities, to have some gymnoti brought to England for the purposes of experiment. The prodigious electric powers possessed by these animals, and the consummate knowledge and skill of the experimenter, lead us to hope for the most interesting results from such investigations.

* I say *generally*, because the experiments of Breschet and Edwards, and of Leuret and Lassaigne, positively show that this result is not constant.

nerves can pass through a small portion of intervening texture like electricity, and *therefore* that this influence is electricity. But this is the only point of resemblance between living nerves and conductors of electricity: in all other respects there is a total difference. The nerves have no known structure which can enable them to conduct electricity better than the solids and liquids that surround them; nor has electricity ever been detected in them during life; although tests have been used which would have detected an electric power infinitely lower than that which could produce the chemical effects ascribed to the nervous influence. Still more opposed to this view, is the fact, that of several nerves in the *same sheath*, some are affected by electricity, and others not; yet these nerves present no physical differences to render some better conductors than others.

2. When the secretion of gastric juice is suspended, and the respiratory function disturbed by the division of the eighth nerves, these functions may be restored for a time by passing an electric current through the nerves. Electricity is also capable of exciting contractions in voluntary muscles. From these facts Dr. Philip concludes that electricity can perform all the functions of the nervous influence, and therefore that the two powers must be identical. But it is not proved that electricity acts in these cases otherwise than as a powerful and effectually-applied *stimulant*, exciting those vital energies which had been paralyzed by the injury to the divided nerves. And it favours this last supposition (as Mr. J. W. Earle has justly remarked), that animals thus acted on by the electric stimulus die much sooner than where the electricity is not applied; in one experiment in two hours and a quarter, in which time it is most improbable to suppose that "inflammation of the lungs, without change of structure," could prove fatal *. Further, electricity does not appear to have the power to restore other secretions, as that of the kidneys, when suppressed by injuries to the nervous system; nor does it counteract the effect of these injuries in depressing animal heat. (See my Experiments.) Lastly, the power of electricity to excite a muscle to contract is shared in common with other irritants, mechanical and chemical, which in no known way can excite electricity, and are inferior to this agent only because they are less effectually applied and diffused.

There are many other objections which oppose Dr. Philip's views in the present state of our knowledge; but I have said enough to substantiate my former statement, that *at present* these views can be considered only as ingenious hypotheses. It is no proof of their fundamental truth that a systematic exposition of the phenomena of life may be based upon them. The systems of Brown, of Broussais, and of many other speculative writers, were framed on views which also were partially founded in nature; but their generalizations were constituted on too narrow and partial a basis; and although beautiful and systematic in their structure, they necessarily crumble under the weighty engines of philosophical criticism.

So also, until the fundamental points of Dr. Philip's views are rendered more unequivocal in their character, and are further established by a proved conformity with ascertained laws of the living and dead matter to which they refer, no ingenuity bestowed on the system erected upon them, no apparent sufficiency of their explanatory applications, will avail to gain for them that respect and homage which are due to the truths of science.

Here, then, is the field for further investigation, in which Professor Faraday has told Dr. Philip that he has "great expectation we shall sooner or later succeed;" but until that success is obtained, dogmatising on imperfectly-established views will retard their reception far more completely than that philosophical opposition which discovers the weak points in their foundation, and demands further research to establish them.

I am, sir,
Your obedient servant,
C. J. B. Williams.

Half-moon Street, Piccadilly,
Dec. 22, 1835.

* I know not on what ground Dr. Philip assumes inflammation of the lungs to be the cause of death in animals subjected to galvanism. His own description of the lungs in this experiment is that they "were rather redder than natural, but otherwise *quite healthy*, collapsing perfectly when the thorax was opened." This is very unlike a fatal inflammation!

MISCELLANEOUS PRACTICAL CASES.

To the Editor of the Medical Gazette.

Sir,

I beg to inclose you a few "Selections from my Case-book;" your insertion of

which, if you consider them worthy of a place in your valuable periodical, will much oblige,

Yours very truly,
P. M. LYONS, M.B. A.M.
Physician-Accoucheur to the Brighton Lying-in Institution.

23, Regency Square, Brighton,
Dec. 22, 1835.

Case of Malposition of the Heart, &c. with Imperforate Vagina.

Harriet Parkes, aged 20, a patient of the Dispensary attached to the Lying-in Institution, had been very healthy until eight years ago, when she contracted a severe cough, with considerable expectoration, of a character similar to her present sputa, and occasional fits of hæmoptysis. She was under medical treatment for six months, and then had an intermission of three months; after which the cough returned, and has not ceased since.

During the whole of this time her appetite and bowels have been pretty regular. Has never menstruated or had leucorrhœal discharge except once, about two years ago, when, while suffering from an attack of what she calls "influenza," she noticed a slight glairy discharge; but this having once disappeared, never returned. About four years back had regular monthly hæmoptyses, which continued four months, and on each occasion lasted one day. Was induced to notice this from its periodicity, in which it differed from the preceding attacks. Since that period has had no return of hæmoptysis. About three years ago was under the care of a surgeon, who gave her emenagogue medicines, that produced considerable pain about the loins and thighs, but without any further effect. Except on that occasion she has never experienced any thing at all resembling a menstrual erethism.

March 18th, 1835. — Present state: tolerably fleshy, though rather leucophlegmatic; appetite good; bowels regular; occasionally troubled with flatus; urine natural; sleeps well; cough severe during the day, with muco-purulent expectoration, which varies in quantity, but on an average amounts to ℥iv. *per diem*, and which, unless immediately yielded to, produces severe headache. On most occasions a mere "hawking" will bring on the expectoration in great quantities, and of a very offensive odour. Pulse 90, small and soft; chest proportionate; mammæ sufficiently developed. No emaciation of chest, though there is a remarkable depression under the right clavicle; one, not so marked, under the left. During respiration the ribs of both sides are equally elevated and depressed, and the intercostal spaces are equally well marked on either side. On right side of thorax, between third and fourth ribs, or at two and a half inches from upper edge of clavicle, and two inches from right margin of sternum, a pulsation is *perfectly visible*, which exactly corresponds to what is produced by the apex of the heart striking against the ribs; while no such phenomenon is perceptible on the left side. On percussion anteriorly, the left side sounds clear, from the clavicle to the tenth rib; but on the right side there is a strongly marked dulness in the region of the first four ribs, which becomes still more appreciable as we pass over the mammary region. The heart's action can be traced over the whole of the right face of the chest. The sternum sounds clear through its extent, though somewhat duller towards the right side; right axilla duller than left; ditto of posterior surface of thorax.

Stethoscopic examination.—Respiration pure over whole face of left side, mamma included; action of heart audible, though slightly, over central portion of mammary region, and somewhat more distinctly more inferiorly. On right side muco-crepitus over humero-clavicular space, which, though it becomes less perceptible as we descend, being masked by the heart's action, is audible as low as the inferior edge of the mamma.

The chest being emptied of the muco-purulent matter by a fit of coughing, cavernous respiration becomes very distinct, and, like the muco-crepitus, is perceptible in the axillary region of same side, as also on posterior surface, where it assumes the character of bronchial respiration. In right humero-clavicular space pectoriloquy (?) is painfully distinct, and extends over the same region as the before-named phenomenon, and with similar alterations and exceptions. At the left side neither of these phenomena is at all discoverable. False ribs descend very low; dulness on percussion over those of right side, but clearness, with respiratory murmur, over same part of left. Bor-

borygmus slightly audible in left hypochondriac region; and when she drinks, the gurgling is perfectly distinct in left hypochondrium, scrobiculus cordis, and over left portion of right hypochondrium, but not at all in right side of latter region.

The result of the preceding investigation having led me to inquire how far the *suppressio mensium* might be dependent on an irregularity in the sexual organs, similar to that in the thoracic viscera, I was induced to request an examination, when the labia and nymphæ were found sufficiently developed, but no os uteri could be detected; while the mucous membrane lining one labium was found to be equally and smoothly reflected over the other, leaving no space or vacancy except for a very small dip or depression, which terminated in a cul de sac.

Having now established the existence of two remarkable facts, first, that the heart was misplaced, and not displaced; and secondly, that there was an adequate explanation for the suppression of the menses; and considering that this last-named functional deficiency kept up, if it did not give rise to, the disease in which the lung was involved, I felt desirous to relieve the chest by establishing (if possible) a menstrual flux; and was supported in this opinion by my friend Dr. Jenks, to whom I feel indebted for the acuteness with which he entered into the investigation of all the different phenomena, which tended to elucidate the various peculiarities of the case, particularly the position of the heart, which *he* shewed must be inverted.

March 19th.—A consultation was this day held—present Dr. Jenks, Mr. Lawrence, and Mr. Kell—with the intent of ascertaining if we might cut down upon the mouth of the uterus; and having learned the real state of that organ, decide whether we would be justified in having recourse to emmenagogues. On this occasion it was finally determined that the symptoms were not yet such as to warrant an operation, or the use of medicines of the above-named class.

22d.—I have daily marked her expectoration, which amounts to four ounces *per diem*, and is strictly of the character already described.

April 1st.—Has this day brought me three ounces of expectoration, in which she says there were traces of blood when it was first ejected.

May 15th.—Has presented herself to me for the first time after a lapse of six weeks; complains of severe pain over anterior of abdomen, and in right lumbar region, especially when she sits. Considering these as merely symptoms of colic, I directed her—

> Subm. Hyd. gr. iv.; Pulv. Opii, gr. ss.; with a carminative rhubarb draught.

16th.—Has had several inefficient attempts to relieve her bowels; complains of some pain in sitting posture, and of a sensation of bearing down, as though some substance wanted to pass per rectum. Urine scanty and loaded, even when recently passed; she then experiences temporary relief.

> Ordered an emollient enema, and warm fomentations to the abdomen and loins.

17th.—Was informed by the person who administered the enema, that there were several large piles protruding from the rectum.

> Directed her some soothing alterative medicines.

30th.—Under the influence of those medicines she has passed her time comfortably, and without requiring to see me until this day, when she sent to request I would call on her. I now found her complaining of increased distress from her former symptoms, particularly the difficulty of making water, and bearing down per rectum. I therefore now proceeded once more to institute an examination of those parts, when I discovered a tumor filling up the space between the labia, and almost protruding into the external parts; it was firm but elastic, extending from the urethra back to the perineum, and in shape and size like a section of a hen's egg.

Examination per rectum.—A large tumor, connected by alæ with either side of the pelvis, projects forwards towards the bladder, and backwards so as almost to block up the rectum. The finger being carefully carried over it, it appears to retain the form of the unimpregnated uterus, though very much enlarged. On percussion being applied with the point of the finger to the base of the tumor, the succussion can be distinctly felt externally; and the external parts being tapped, the sensation is immediately conveyed to the base of the tumor. On exploration no tumor could be detected in the abdomen; but pressure being applied deeply and

forcibly, the tension of the tumor was considerably increased.

Having now determined both the nature of the case, and the only feasible mode of relief, I proceeded on the following day, in the presence of Dr. Jenks, Mr. Davies, R.N., Mr. Kell, and Mr. Best, surgeons to the Lying-in Institution, to make a free incision into the vagina, when there gushed out twenty ounces of a brown, streaked, thickish fluid, closely resembling tar in all its qualities, smell and viscidity excepted. A dossil of lint was afterwards inserted into the opening.

June 2d.—Has had a free discharge of limpid urine since the operation; bowels have been relieved spontaneously; no fever; a considerable quantity of menorrhœal fluid has strained away, the colour of which is now beginning to be changed. On examination, the os uteri, which is thick but very patulous, is in immediate approximation to the opening; the transverse rugæ are very perceptible to the touch. I now introduced a female syringe, and continued it for three hours a day during four days, after which it was replaced with a sponge tent, the parts were thoroughly injected with tepid water, and on the sixth day the discharge became free from colour, &c.

10th.—Says she does not spit up within one-third of what she used to do previous to the operation; cough and hawking less troublesome.

12th.—Has had a slight coloured discharge, which began on the 10th, increased in quantity yesterday, but is less in quantity and paler to-day.

July 12th.—Has had occasional exacerbations and remissions of cough since last report, but has been generally going on well since. Expectoration never more, sometimes less, than two ounces *per diem.* Has had no menstrual return since 12th of last month, but an increased leucorrhœal discharge during the last three days; looks and feels much improved in her general health; chest sounds clear on percussion; mucocrepitus hardly perceptible, except on coughing, when it becomes very distinct over the inferior anterior portion of the right thoracic cavity, and over all the greater bronchial tubes of the same side. Vocal resonance much less distinct, except posteriorly; indeed, anteriorly it hardly enters the tube of the stethoscope.

Dec. 19th.—Has continued to menstruate, with some irregularity, constantly since July. Her cough, which during the summer months appeared to improve, has resumed its original severity; and in point of expectoration, as, indeed, in almost all the other pulmonary symptoms, she is in much the same position as that in which I originally found her; but her health withal does not appear to suffer. I have recently introduced a seton over the right side, and am trying the effect of the terebinthinates, but as yet with nothing like marked success.

REMARKS.—The foregoing case, full as it is, calls for few if any remarks from the author, save an apology for publishing it in its present unfinished state; but when it is remembered that it has already extended over a period of eight years, and may probably reach as many more, without the patient's health undergoing any material alteration, the author feels that he will be excused, if not justified, for wishing it to be now placed upon record.

Case of excessive Quantity of Opium being taken without fatal Results.

The mother of Marianne Croskey, a healthy infant, aged four months, and residing at No. 1, Little St. James's-street, states, that on leaving home on the 5th of May, 1834, she left her child in care of a woman who was an inveterate opium-eater, and who shortly after gave the child a lump of opium, which she describes as having been of the size of a small pea, and a third less than her own ordinary dose. Coma immediately set in; and the woman being alarmed, went, at 8 A. M., to a respectable practitioner, who, seeing the child livid and comatose, and having heard the quantity administered, pronounced that the child could not recover, and therefore declined taking charge of it, though he subsequently saw it at 12, and again at 2 P. M.

At 3 P. M. the parents sent to request that I would go and see the child; but being from home when the message was left I did not see it till 4 P. M., when I found that the midwife of the Lying-in Institution, who had arrived shortly before me, had put the child into a warm bath, and was briskly rubbing the abdomen and limbs. State of the child,—sensation and motion none, countenance livid, pupils dilated, no pulse at either wrists or arms, heart feebly beating

45 per minute, The child being in the bath, I directed a full-sized teacupful of warm water, with a teaspoonful of castor-oil and a saltspoonful of common salt to be administered as an injection; and proceeding to a chemist in the neighbourhood, procured an ounce of vinum ipecac. and the following mixture:—

℞ Sp. Am. Arom. ʒss.; Sp.Anisi ♏xx.; Syrupi Croci, ʒij.; Aquæ Anethi, ʒxij.; ft. Mist.

I now proceeded to give the child a teaspoonful of the stimulant, with one of warm brandy and water, every quarter of an hour. This was at first done by putting the spoon far back towards the pharynx, and then closing the mouth upon it. After the first three doses vitality seemed slowly to return. I now began to add a teaspoonful of the vinum ipecac. to each one of the stimulant, and repeated this every ten minutes until vomiting was produced, which commenced at 5½ P.M.; when the infant being put into another warm bath, and a second injection administered, the bowels were relieved of a dark, offensive stool, but possessing scarcely any odour of opium. After this, stimulants were continued every quarter of an hour until 6½ P.M., when the breast being milked into its mouth, the child was sufficiently revived to be able to swallow of itself. I now left it, having first given directions that a teaspoonful of oil was to be administered every hour, and an injection every two hours, until the opium was voided, recourse being had in the interim to occasional small doses of the stimulant. 8 P.M. saw the child again, who is considerably revived. 10 P.M. Bowels have been relieved three times since last report: the last motion smelt strongly of opium. The baby has taken the breast freely, and for some time. The castor-oil to be repeated every two hours, until I see the child in the morning.

May 6th, 11 A.M. Am informed that at 9 o'clock this morning there was found on her napkin a small, softish, but firm lump, of a deep black colour and strong smell, which had been put by for me, but was subsequently removed by one of the neighbours. From this time the infant had not a single bad symptom. I am informed that the surgeon who first saw the child, and who, like myself, saw the mass from which the lump was taken, pronounced it to be crude opium, which was also my own conviction.

Case of General Dropsy, complicated with Enteritis.

Wm. Furnnell, aged 6½ years, was healthy as an infant, but during the last five years has been subject to periodical attacks of diarrhœa, recurring monthly, and lasting each from three days to a fortnight. Has suffered at times from acute pains in the kidneys, which were generally relieved by vomiting: immediately after his first attack of this kind, passed a calculus of about the size of a pea. Urine usually very scanty. Six months previous to my seeing him, had an attack of diarrhœa, for which he was admitted as an out-patient of the General Dispensary, and attended by Mr. Parsons (then house-surgeon), who, viewing the case as one of enteritis, treated him first antiphlogistically, and subsequently with astringents; under which mode of practice the enteric symptoms disappeared, but his face and upper extremities began to swell, and, on their subsidence, the abdomen and lower extremities assumed a dropsical tendency. He was now put upon a course of diuretics, when the enteric symptoms immediately reappeared. I was therefore requested to visit him, in my then capacity of physician to the General Dispensary.

September 20th, 1833.—Present state, no great emaciation; countenance pale, not bloated; pulse 90, hard; tongue coated at the centre, tip and edges red; papillæ rather prominent; abdomen, superior portion tympanitic in erect position, but fluctuating when supine. Measurement around umbilicus 30½ inches. Scrotum and prepuce transparent, and so distended as to compress the orifice of the penis, the whole body of which organ is excessively twisted, whence pain extends along the course of the spermatics. Lower extremities very much swollen; tenderness, amounting to pain, on pressure, along the whole tract of the colon. Stools purged, mixed with pus, and what looks like small shreds and larger patches of the lining membrane of the intestines. Urine scanty, not more than ℥xij. in the twenty-four hours, of a pale straw colour, inodorous, and coagulating on the application of heat.

Directed that no food or drink be given him under *any circumstances*, ex-

cept one pint of milk in the twenty-four hours, and that in minutely divided portions; the scrotum to be punctured in different places with a cambric needle; ʒss. of mercurial ointment to be rubbed into the sides of the abdomen at bed-time, and one of the following pills twice a day:—

℞ Pil. Hyd. ℈j.; Pulv. Dov. gr. xij. ft. Pilulæ viii.

22d.—Scrotum has not been punctured; pain along the course of the spermatics intolerable. My friend Mr. Haviland, one of the surgeons to the Dispensary, being then with me, at my request freely punctured both scrotum and prepuce. The bowels being irritated by the use of the blue pill, I determined to omit all internal medicine, and abide the result of inunction, which was directed to be applied twice a day to the abdomen, groins, and axillæ.

25th.—Breath redolent of mercury. Though stinted to his pint of milk, has voided, in the twenty-four hours, two quarts of urine, which gives evidence of the presence of a large quantity of albumen. Measures 25 inches across the umbilicus. Scrotum and penis very much diminished, but still exuding. Pergat.

27th.—Discharge of urine increased by a pint per diem, but still albuminous. Measurement of abdomen 22 inches. Scrotum and penis of their natural size; perforations healed; lower extremities very much diminished. Has had but two motions each of the last two days, both of which were of a reasonably healthy character; still some slight tenderness on pressure. Pergat.

October 3d.—He has gone on favourably since last report; no change has therefore been made except in his diet, which has been gradually improved by the addition of an egg beaten up in the milk; some plain animal jelly, and a very small quantity of bread. The mercury appearing to have completely affected his system, I have this day discontinued the use of it, and ordered him three tepid baths, with a day's interval between each.

8th.—On his taking the second bath (which was salt water, all our public baths, with one exception, being of that description), the abdomen began to swell rapidly, and his urine to be diminished in quantity, but increased in albuminous quality. Omit the baths, return to the ung. hyd., and let one of the following powders be taken twice a day:—

℞ Hyd. c. Creta, ℈ij.; Pulv. Dov. gr. x.; Pulv. Calombæ C. ℈ij. Ft. pulveres decem.

18th.—Since last report he has been steadily improving up to this day. Present state, bowels rather confined; pain in the region of kidneys; urine scanty and highly albuminous.

℞ Sp. Æth. Nit. ℥ss.; Potass Nitrat. ℈j.; Syrupi, ℥ij.; Aquæ Puræ, ℥vi. M. Coch. Parv. e. Decocti Hordei Cyatho vinoso; ter die sumat. Rep. Pulveres, Olei Ricini, ʒj. quoque mane quum opus sit. Ung. Ant. Tart. ʒij.; Adipis Nullæ, ʒij. tere; lumborum lateri utrique nocte infricetur, ʒj.

20th.—Pain in kidneys has disappeared; urine more copious, scarcely albuminous; abdomen has again returned to its natural size.

Pulv. Calombæ C. ʒj. in par. xij. ter die. To be removed to the country as soon as possible.

24th.—Every unfavourable symptom having disappeared, he goes into the country this day, taking with him 24 powders.

November 1st.—His mother informs me he has had no unfavourable symptom since he left, but is gaining flesh fast, and beginning to enjoy all his boyish amusements.

This boy has not had a return of his attack since, and is now a strong and healthy lad.

Remarks on the foregoing Case.—The dropsy was evidently dependent on renal irritation, but complicated with enteritis, so as to render inadmissible the use of ordinary diuretics. Mercury, therefore, appeared to be the agent most capable of acting with advantage over both affections; but even this remedy was not available by the mouth, as, when so administered, it increased the irritation of the bowels: inunction seemed, therefore, the most advisable form for administering this mineral, to which was united a system of dietary which, while it afforded a sufficient degree of mild nutriment, greatly diminished the ingesta, thus at the same moment removing a very fruitful source of irritation from the bowels, and, by relieving the absorbents, allowed them to expend their increased action upon

the extravasated fluid; a mode of practical dietary which, though not in exactly similar cases, has been had recourse to with advantage by Dr. Wm. Hunter and Mr. Hey, of Leeds; as noticed by Dr. Todd, in his valuable Treatise on Indigestion *; and which was the more admissible in this case, as my little patient was by no means deficient in muscular power.

Case of Sudden Death nineteen Days after Uterine Hæmorrhage.

Charlotte Thorne, aged 29, married three years, of a leucophlegmatic temperament, had, during the period of her first pregnancy, suffered severely from gastric irritation, accompanied with cough and mucous expectoration, and at the time of the accouchement was in a most debilitated state. The child was still-born; the mother recovered slowly, and in about six months after became again pregnant, when she had a recurrence (though milder) of her former complaint. Oct. 19th, 1833, was seized with labour-pains about 2 A. M., and about 6 sent for me; who, finding the os uteri an inch in diameter, continued with her. From this time the labour went on very favourably, though slowly, until noon, when the child was born; and in twenty minutes after the placenta was thrown off; but instantly followed by a sudden and violent dart of blood, which could not be suppressed by pressure, cold applications, or the secale cornutum, though given in repeated doses; I was therefore compelled to introduce my hand, when I found the uterus perfectly flaccid, and so relaxed as to ascend before my hand into the left hypochondrium. Neither the motion of the fingers, nor yet rapping the walls, produced any tendency to contraction; I was therefore obliged to make forcible pressure on the uterus externally with my left hand, while the right continued in the cavity of the viscus. In this manner a perfect and permanent contraction was at length effected, but not before my patient had lost all power of speech and motion: her pulse was scarcely perceptible. All the usual means of resuscitation were now had recourse to (transfusion excepted), and with success, as she continued to improve gradually until 9 P. M., when I directed for her—

Pulv. Opii, gr. iij.; Acet. Plumbi, gr. vj.; Confect. Aromat. q. s. ut ft. Pilulæ tres, i. q.q. horâ tertiâ.

20th, 8 A. M.—Found she had passed a tolerable night; had taken some warm jelly with wine: pulse 90, and steady though small and soft.

21st.—Has passed a very tolerable night; eyes bright, countenance cheerful; is anxious to put her baby, which is a strong one, to the breast (as the milk has begun to appear), which I have permitted.

After this I saw her each day until the 1st of November; when, finding her steadily progressing, and nursing her child, I ceased my visits, and heard no more of her until the 7th, when I was called at 4 A. M. to see her, but on reaching her residence, learned she had expired at the moment in which the messenger had left the house. On inquiring the particulars of her case from the time I had seen her last, I was informed she had gone on nursing, and, as her friends thought, improving, up to the morning of the 6th; that on that day she had left her room, and having been visited by several of her friends, had exerted herself more than usual; but had complained once or twice in the course of the day of a sensation of internal sinking, which became more frequent towards night, though she did not allow it to prevent her sitting up until 10 o'clock, and nursing her child; that at 3 A. M. she roused her nurse in consequence of this sensation; who, having procured her some nourishment, and placed her, at her own request, in her chair, she leaned her head back and expired.

Nov. 9th, 2 P. M., I proceeded to inspect the body, in company with Mr. Haviland. The body, round and well formed, was sufficiently covered with fat. On opening the chest, the lungs, which filled about two thirds of the pleura, crepitated freely throughout. When reflected forward, they shewed no trace of that dark redness which is generally observed at the back and root of the lungs, and is consequent on the gravitation of the blood; but in each pleura was found about ℥iij. of a dark-coloured serum: the pericardium contained about ℥ss. of the same kind of fluid. The heart was softened, flaccid, and contained neither coagulum or fibrin; nor was there any appearance of venous blood when

* See article "Indigestion;" Cyclopædia of Practical Medicine, vol. ii. p. 636.

the cavæ were cut through. All the vessels were healthy, as were the viscera of the abdomen, with the following exceptions:—The mucous membrane of the stomach, which contained about a teacupful of mixed food, presented small scattered patches, of a pink colour; and the membrane generally was so soft as to yield to a slight pressure of the nail. The liver was small, hard, and of a nutmeg colour. The uterus, which was of the size and shape of a large-sized pear, was soft to the touch, and on pressure gave exit to about a teaspoonful of a brown, thinnish fluid, somewhat resembling the menstrual discharge when recent. The friends would not permit the head to be opened; and as there was a total absence of every symptom which might be considered indicative of cerebral affection, I did not deem it necessary to press for permission to examine it, when contrary to their wishes.

In conclusion I shall beg to observe, that if this be a case of death from anæmia, as I certainly consider it, we must look to three different circumstances, or rather to an untoward combination of them, as the cause: first, the severe hæmorrhage which followed the accouchement, and which reduced her to a very low ebb; secondly, the diseased state of the digestive organs, which prevented the restorative process going forward with sufficient rapidity; and lastly, the constant drain which lactation, in her ensanguined state, must necessarily have produced upon the constitution; which, though equal to resist this depressing combination as long as the patient was kept in a state of repose, was forced to yield to the first powerful call for either mental or bodily exertion, or both, as unfortunately occurred in the present instance.

Should this view of the case be considered correct, it will necessarily oblige us to think seriously before we finally determine to adopt, as a rule of practice, the advice recently given us in such cases, even though emanating from one of the most respectable authorities in modern midwifery, who, having advanced the propositon, "Ought patients who have experienced considerable hæmorrhage in labour, to be allowed to nurse?" replies to it in the affirmative*. Highly as I esteem that gentleman, as an authority in all practical points, I cannot help considering, as the result of my own experience, that though the immediate application of the child to the breast in cases of slight hæmorrhage, or rather where there may be an hæmorrhagic tendency, in the manner recommended by Dr. E. Rigby, is frequently productive of considerable advantage, by causing a revulsion of blood from the uterus, and at the same time exciting in that organ a tendency to contract,—a perseverance in nursing, after a severe hæmorrhage or other extremely debilitating affections, often lays the foundation of diseases worse in character than those which it is intended to obviate.

* See a paper on some peculiar forms of Relaxation of the Uterine Tissue, by Dr. Montgomery, in the Dublin Journal of Medical and Chemical Science, Nov. 1835, p. 235.

Case of Galactorrhœa.

Martha Burchell, a patient of the Dispensary attached to the Lying-in Institution, aged 33, of a clear complexion, excepting a dark ring around the eyes, states, that milk began to be secreted about a month previous to her first accouchement, and in her other subsequent pregnancies became perceptible at the period of quickening. Immediately after she had quickened of her eighth child, the left mamma became hard and painful, and finally suppurated in several different places, all which continued to discharge until three months after her accouchement; the right breast secreted milk freely until the last month of her pregnancy, when it likewise inflamed and suppurated. At the expiration of the third month after her confinement, the child being weaned, and the milk ceasing to be secreted, the abscesses healed spontaneously. The Christmas following she again became pregnant, and quickened in April, when, milk being secreted in the left breast, she was immediately attacked with pain in the right one, which subsequently inflamed and suppurated, and has been discharging pus during the last week.

July 1st, 1832.—Pulse 90, soft; night sleepless; tongue pale, but clear; lips furred in the mornings, with coppery taste; bowels rather costive, flatus; urine high coloured; subject, both day and night, to cold clammy perspirations, accompanied by faintness; hands and feet constantly cold. Around the nipple of right mamma there is a large nodulated, but not hard, mass, with a halo of

inflammation immediately encircling the nipple. This lumpy portion extends deeply backwards, and thence towards the axilla. None of the glands in this neighbourhood are involved, nor does the breast feel heavy in proportion. Below, and external to the nipple, is an opening, through which an abscess is discharging freely. Left breast soft and flaccid, except in a single point, where it is both hard and painful.

Having learned that my friend, Dr. Todd, had on the former occasion been consulted by the gentlemen who then had charge of her, I called on him, and at his suggestion adopted the following mode of practice:—

℞ Extracti Conii, gr. x.; Pil. Hyd. gr. xvi.; Pil. Galb. c. ℈ij.; Ft. Pilulæ, xvi. Unam nocte maneque sumat.

July 4th.—Abscess in right breast still discharging, but all around soft. An abscess has formed in left breast, where the hardness had previously existed; this she will not allow to be opened.

A linseed poultice to be applied to this, but one of recent hemlock to that which is discharging, and let the sides of the breast be smeared with the following ointment:—

℞ Ext. Conii. recentis, Ung. Hyd. Axungiæ, aa ℥j. ft. Ung. bis die utendum.

One of the pills of Hyd. c. Conio to be taken three times a-day.

12th.—Abscess in left breast has ulcerated.

Apply the Hemlock Poultice to it also; increase the Hemlock in the pills to gr. xx. ter die sumat; omit the Ointment, which has caused some irritation, and let the sides of the breasts be gently rubbed with Rum and Oil.

20th.—The mercury having slightly affected the mouth, it is be omitted, but the cicuta and pil. galb. to be continued as before. The abscess in right breast is healed, but another is forming immediately in its neighbourhood.

23d.— Some serous discharge from both nipples; a good deal of fever.

Apply the breast-pump, to try if the breasts can be relieved.

Pulv. Jalap c. ℨiss. in p. iii., i. q. q. hora, 4ta.; Mist. Salinæ Coch. ij.; Comp. q. q. hora 2da.
Repr. Frictiones.

24th.—Fever still high; no milk to be obtained by pump or fomentation, though there is still some serous discharge.

Repr. Pulv. Jalap. c.; Omit. Pil. pro. temp.; Omit. Breast-pump; continue the Hemlock Poultice, except over the incipient Abscess, over which apply a Linseed Poultice.

28th.— Abscess ulcerated and discharging.

Apply Hemlock Poultices to the wall of both breasts; renew Pills as on 20th.

August 5th.— Ulcer healing.

Pergat omnibus.

13th.— General health rapidly improving; breasts becoming flaccid; ulcer healed.

Pergat.

20th.—Still improving in every respect.

Repr. Med. Omnia.

28th.—Health, both general and local, so much improved, as to admit of my laying aside the poultices and one pill per day. A slight serous exudation from nipples.

Sept. 4th.—Says she has not enjoyed such good health, when so far advanced, for some years. Breasts quite healed; no apparent tendency to absorption; a drop of fluid still exuding from each nipple.

Repr. Pil. ut die postero.

11th.—Flying pains about the uterus; in every other respect extremely well.

Oct. 2d.—Was this morning delivered of a fine healthy girl, who, in two hours after, was applied to the breast, and obtained milk.

From the above date she went on, without a moment's check, until her recovery was complete; but at the end of the second month she was obliged to wean the child, from want of milk.

REPORT OF FRACTURES

TREATED IN THE LONDON HOSPITAL DURING NOVEMBER.

To the Editor of the Medical Gazette.

Sir,

I enclose you the monthly report of fractures admitted into the London Hospital during November last. They amount in number to 42, and are in the following proportions:—

Cranium	1
Ribs	10
Clavicle	3
Humerus	3
Forearm	1
Radius	3
Femur	7
Patella	1
Tibia and Fibula	8
Tibia alone	3
Fibula	2
	42

I regret that I cannot furnish you with a strict account of the side of the body on which the greater number of the accidents have occurred.

I have the honour to be, sir,
Your obedient servant,
JOHN ADAMS.

New Broad-Street,
Dec. 1835.

DEFENCE OF

DR. ELLIOTSON'S EMPLOYMENT OF IODINE,

AND OTHER REMEDIES.

To the Editor of the Medical Gazette.

SIR,

THAT love of justice and strict impartiality which ought invariably to characterize alike the editor and the critic, will, I doubt not, insure for the following observations an insertion in the forthcoming number of your valuable periodical; more especially as they refer to a communication from Mr. Forbes Winslow, which was published in the Gazette of Saturday last.*

In the communication above referred to, Mr. Winslow has adduced the opinions entertained by Dr. Elliotson, Dr. Addison, and himself, respecting the efficacy of iodine as a therapeutical agent. With his remarks on this subject I can of course have nothing to do, inasmuch as most practitioners deduce their conclusions from facts which they have themselves observed, or from those which have occurred under the cognizance of individuals of acknowledged credit and respectability, and have by them been made known to the profession generally.

Not so, however, his insinuations respecting the practice of Drs. Elliotson and Addison: they may and do legitimately fall within the pale of inquiry, he having in a strange, and, I must say, unwarranted, manner, made assertions concerning the professional character of these celebrated physicians which, if correct, would tend to hurl them from that station to which, as well by their literary and scientific, as by their professional acquirement, they have been so justly elevated.

I have witnessed, for a considerable period, the practice of Dr. Elliotson at the North London Hospital; and not having been, I trust, altogether inattentive, I may perhaps be allowed to state that your correspondent's assertion respecting his *indiscriminate* use of iodine is totally unfounded, and that Mr. Winslow appears to have deduced his conclusions from incorrect and consequently imperfect premises. Not that I wish it to be understood from this that Dr. Elliotson seldom employs iodine; on the contrary, it is a remedy which he very frequently prescribes, and this, indeed, with the most beneficial results, as is well illustrated by a reference to the clinical reports, from which it will become apparent that eight-tenths of those patients who are treated with this remedy are discharged cured or relieved, and this, indeed, without the exhibition of any other therapeutical agent.

This fact alone speaks volumes, and is, I imagine, sufficient to overthrow all the preconceived ideas of your correspondent.

Lastly, with regard to its empirical administration, which, if not expressed, is at least evidently implied in Mr. Winslow's communication. As a refutation of this I need only refer your readers to the Doctor's clinical lectures, from a careful perusal of which I think it must appear evident, even to the most sceptical, that in all cases where administered, its use has been not only clearly indicated, but also that its exhibition has been directed by scientific and general principles.

That the charge now adduced by Mr. Winslow against Dr. Elliotson, with regard to iodine, has been heretofore urged against him on the subject of other remedies, I am ready to allow; but do not all these circumstances tend to prove, by the universal assent now given to the opinions which he has invariably maintained, that his ideas on

* We should have given immediate insertion to the present letter, had Mr. Munk sent us his name in the first instance.—E. G.

these points were founded on correct bases? What effect do those sarcasms now produce with which he was so continually assailed on first introducing quinine* to the notice of the British public, and proving to them by a series of well conducted and well regulated experiments, that it was a remedy possessing herculean powers over certain conditions of the system; but that to obtain its specific effect in peculiar states of the economy, it was requisite to administer it in doses which set at defiance all the preconceived opinions of its discoverer.

Are not the facts obtained by him respecting the efficacy of iron† in chorea—of hydrocyanic acid‡ in gastrodynia — of sulphate of copper§ in dysentery—of hydriodate of potassa‖ as a diuretic—of creosote¶ in vomiting, *not* arising from inflammation—highly useful? And have not the conclusions which he has deduced from the facts he has observed been treasured up by his contemporaries, and made use of by them in the alleviation and cure of disease? Do the invectives of his brethren at all invalidate the conclusions at which he has arrived? Do they prove that he has been empirical or indiscriminate in their administration? Certainly not.

In conclusion, I may inquire of Mr. Winslow, in what manner the application of new remedies to particular conditions of the system are to be discovered, or their actions understood, unless it be by the collection of facts; and how are these facts to be obtained but by the administration of the remedy?

I am, sir,
Your obedient servant,
W. Munk.

DOES IODINE CAUSE SALIVATION?

To the Editor of the Medical Gazette.

Sir,

Allow me to ask, through the medium of the Gazette, your correspondent, Dr. Ely, of Chatham, what length of time elapsed since his patient had taken mercury and the iodine was prescribed?—as facts, I agree with the Doctor, are valuable in practical medicine. But, sir, I do not admit it to be a fact, although the salivation occur during the administration of the iodine, that it is produced by the latter, but quite the contrary, or surely the cases would be more numerous on record.

I look upon iodine salivation as untenable as sarsaparilla salivation, which some few years back was occasionally mooted, but very rarely now. And how is this, I would ask? For the plain reason, that when any of those cases were duly investigated, the salivation was found to arise either from a prior use of mercury, or the preparation of sarsaparilla containing it in solution. There is another point that I am sceptical about in salivation. We have well-written cases purporting to prove the wonderful effects of a single dose of mercury. Probably the dose has not exceeded one-eighth of a grain of calomel, or at the most iij. grs. This susceptible state of the constitution to the peculiar action of mercury, I have not as yet met with, although I have examined two cases where it was supposed to have occurred from a single dose, when, in truth, that dose only proved as an excitant to excite that action of the salivary glands which had not become previously developed; and it is this same stimulating power that iodine exerts over those organs to cause the same phenomenon—salivation. But of what avail would the stimulus be unless the system contained mercury? I am induced to ask the above question, hoping it may furnish data as to the time which may elapse while the action of the mercury, as it were, may remain dormant in the system, and then shew itself.

I am, sir,
Your obedient servant,
Jas. H. Horne.

Gerrard-Street, Dec. 29, 1835.

SEQUEL OF THE BRENCHLEY CASE OF FORCIBLE LITHOTOMY.

[It will probably be recollected, that some months ago (Med. Gaz. vol. xv. p. 920,) we had occasion to notice the forcible attempt made by a surgeon and clergyman at Brenchley, to perform the operation of lithotomy on a pauper boy;

and for which the parties were tried at the Maidstone Spring Assizes. The unfortunate patient does not seem to have survived the violence long: though we by no means intend to attribute his death to what he suffered under the surgeon's hands—having no ground on which to rest such an opinion. For the following clear and strictly authentic account of the morbid appearances about the urinary organs, we are indebted to an eminent anatomist, who was intrusted with the examination of the body.—Ed. Gaz.]

Appearances observed in the post-mortem examination of James Roberts, æt. 16, who died in the Poor-house of Brenchley, on Friday, July 17, 1835.

The body was thin, but not emaciated; it presented none of the ordinary signs of puberty. On the right side of the raphe, about the centre of the perineum, was observed a dark spot where the integuments were smooth and thin, which indicated the situation of the incision made in the endeavour to extract the calculus. By pressing upwards towards the bladder on this spot, a hard substance (which afterwards proved to be the calculus,) was distinctly felt. The kidneys, ureters, bladder, and urethra, together with the rectum, and the integuments and subjacent parts of the perineum, were removed.

The kidneys were large and flabby; their cavities were dilated, and their lining mucous membrane was thickened, vascular, and in places encrusted with lymph. In the left kidney were found some deposits of pus in the cortical portion, and a quantity of muco-purulent fluid in the pelvis. The ureters were much dilated. The bladder was larger and thicker than natural, and its mucous membrane was dark-coloured and thickened, particularly about the neck, where it was partially ulcerated. The neck of the bladder and the prostatic portion of the urethra (particularly the latter) were considerably dilated, as well as its membranous and bulbous parts. They formed together a large sac, or rather canal, in which was lodged a calculus, extending from the orifice of the bladder to the bulbous part of the urethra. The mucous membrane of the neck of the bladder, and of the prostatic portion of the urethra, was ulcerated extensively. The prostate was flattened by the dilatation of its urethral canal, and it was difficult to distinguish the exact boundaries of the prostatic and the membranous parts of this tube. In the lower part of the bulbous portion of the urethra (which lodged one extremity of the stone) was found a small pouch which extended to the thin part of the integuments of the perineum, which had been the seat of the incision. In front of the bulb the urethra was healthy, and of its natural size.

The calculus measured about three inches in length, and three-fourths of an inch in its greatest diameter; it was apparently composed of the triple phosphate of ammonia and magnesia.

One extremity of the stone projected into the bladder; below this part it had a constriction which was embraced by the neck of the bladder. The body, or large central portion of the stone, rested in the dilated prostatic and membranous parts of the urethra. It had another constriction corresponding to the anterior extremity of the membranous part of the tube, and beyond this, a second head, which was lodged in the dilated bulb, and which was that part of the stone which could be felt with the finger from the perineum.

The calculus appeared to be so lodged and embraced by the surrounding parts as to be immoveable; so that the urine must have dribbled away by its sides. The incision in the perineum must have laid open the bulbous part of the urethra.

The kidneys, bladder, and calculus, are preserved in the Museum of King's College, London.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue a abréger."—D'Alembert.

Nouvelles Recherches sur le Rheumatisme articulaire aigu en général, et spécialement sur la loi de coïncidence de la péricardite et de l'endocardite avec cette maladie, ainsi que sur l'efficacité de la formule des émissions sanguines coup sur coup dans son traitement. Par J. Bouillaud, Professeur de Clinique Médicale à la Faculté de Médecine de Paris.

The design of M. Bouillaud in this work is to prove the pathological coincidence between pericarditis and rheumatism, and the practical efficacy of blood-

letting, "*coup sur coup*," in its treatment.

In order to establish the former proposition, he in the first place examines the opinions of various writers, particularly among his countrymen, in order to shew that they have only mentioned the subject incidentally, which, indeed, would seem to have been the case with Corvisart, Laennec, Chomel, Andral, and Louis. But when the author extends his observations to English writers, we find no other authority quoted except that of Dr. Hope. The inference to which we are naturally led, both by the doctrine of M. Bouillaud and the manner in which he endeavours to establish it, is, that he is himself very ignorant of the state of medical practice in this country. There is probably no point in modern practice more firmly established than the connexion between acute rheumatism and inflammation of the investing membranes of the heart; and that Dr. Hope did not direct more especial attention to the circumstance, is to be attributed to his well-grounded conviction that to have done so would have been to insist upon a fact already perfectly well known. He therefore contented himself with stating in general but express terms, that in acute rheumatism the most frequent, as well as the most pressing danger, resulted from the supervention of carditis or pericarditis.

The only novelty, therefore, in the pathology of M. Bouillaud, appears to us to consist in a question of degree. All who have seen much of acute rheumatism will readily acknowledge that the coincidence of it with pericarditis is very frequent; but M. Bouillaud puts it interrogatively, whether in the great majority of cases of acute general articular rheumatism, with fever, there does not exist rheumatic inflammation of the sero-fibrous tissue of the heart. This coincidence, therefore, with him is the rule, and its absence the exception.

He admits, however, that the rheumatic inflammation about the heart may exist in many different degrees of intensity, and shields himself against the charge of having represented it as more common than it really is, by implying that its presence often escapes the investigations of the unskilful. The symptoms which indicate inflammation of the pericardium as a concomitant of rheumatism are thus described by M. Bouillaud:—

"The existence of pericarditis in a patient affected with acute articular rheumatism becomes certain when we observe the following symptoms:—Dulness of the precordial region; much more extended than in the natural state, being doubled or tripled in every direction; projection of the same region; beating of the heart distinct; little or not at all sensible to the touch; sounds of the organ remote, obscure, accompanied by various anormal *bruits*, some depending upon friction of opposite surfaces of the pericardium against each other, and others proceeding sometimes from the complication of the pericarditis with inflammation of the valves of the heart. Pain more or less acute in the precordial region, palpitations, irregularity, inequality, or intermission, of the pulse, are sometimes added to the preceding symptoms.

"The coincidence of endocarditis with acute articular rheumatism I hold to be certain when we have the following symptoms:—The bellows, rasping, or sawing *bruit*, in the region of the heart, which further yields a dull sound over a space considerably larger than natural, and presents also a certain degree of projection, though less than we witness in pericarditis with effusion. The action of the heart raises the cardial region remarkably, and is generally irregular, unequal, and intermittent, sometimes with a vibration or tremor, the pulse being hard, strong, and unequal, corresponding to the beating of the heart."

The above description is followed by the detail of a considerable number of examples, not fewer than twenty cases of rheumatism having been met with by our author between the month of August, 1835, and the beginning of October. These consist of three series: the first consisting of general acute articular rheumatism, accompanied by fever more or less severe; the third set consists of those cases in which the rheumatism was slight, and without fever. Between these two is another category, containing those cases in which a lesion of the heart, supposed to be organic, was met with in persons formerly affected with rheumatism of an acute character and frequent recurrence. The list of these is intimately connected with the two

others, and the organic lesions it displayed are held to have been endocarditis, or pericarditis, in a chronic form; that is to say, with accidental productions which had resulted from the previous inflammation. And assuming this reasoning to be correct, it gives us a rheumatic affection of the heart or its membranes, in eight cases out of nine of acute articular rheumatism.

After the relation of twenty cases of rheumatism in support of the above opinion, M. Bouillaud proceeds to consider the symptoms, progress, intensity, duration, and termination of the disease. Of these subjects the only one in which we find sufficient novelty to arrest us, relates to the *mobility* of the disease. He holds that acute articular rheumatism is not capable, according to common belief, of rapidly changing its seat, or rather of being very suddenly dissipated. If, for example, there be considerable swelling of the knee, with effusion into the joint, it is true that the pain of the joint may suddenly cease, with or without occurring in another part; but it is not always the same with the effusion, which he holds to be the essence of the disease, the mere pain being only a kind of neuralgic symptom. Rheumatism of the joints, which does not exceed a certain degree of severity, may shew a great mobility; but such is not the case with rheumatism of a more intense degree, which tends to suppuration, or which has already terminated in a sero-purulent effusion. This, if left to itself, is not dissipated until after the lapse of considerable time; but the pain which accompanied it may disappear long before the articular effusion, just as a pleuritic stitch in the side may cease before the reabsorption of any effusion caused by the inflammation.

A remarkable fact, according to our author, which has itself been observed, although its cause has escaped detection, is the persistence of fever in some rheumatic patients, although the joints have long been free from the disease. The alleged cause, to which M. Bouillaud attributes great importance, is the existence of rheumatic inflammation of the heart, vessels, pleura, &c., which hold on their course in a manner completely indolent,—a circumstance which has led to their being so generally overlooked. This is also regarded as an additional proof that pain is not essential to rheumatism, and that this effusion is not so mobile as has been supposed, since in the cases alluded to it is so rooted as to keep up a state of fever for many successive weeks.

In speaking of the morbid anatomy of rheumatism, M. Bouillaud remarks, that suppuration is of more frequent occurrence than has been supposed. He quotes the authority of Stoll in support of this opinion, and informs us that he has himself seen three cases in which rheumatism terminated in suppuration of the joints. Two of these are detailed; the first is as follows:—

"April 11th, 1828. The body of a young woman was opened at La Charité, she having been affected with acute articular rheumatism, in the course of which a pleurisy supervened; the patient was only fifteen days in the hospital. The left knee-joint internally was red, somewhat dry; condyles of the femur eroded; no pus. The right knee-joint was filled with genuine pus, mixed with synovia. There was but little sanguineous congestion (during the last days of her life the patient had ceased to have pain in this joint). One of the wrists was red, and evidently inflamed. The portion of the crural vein nearest the joint which contained pus, was filled with purulent matter, mixed with reddish sanies; in all the rest of its extent it was obliterated by a coagulum, as were its subdivisions; at various points a certain quantity of pus was observed. The parietes of the vein were thickened, particularly towards the knee; the artery was healthy; the nerve which accompanied the vessels was redder than natural, and sensibly enlarged."

"Of five cases of articular rheumatism, mentioned in a summary of my clinique, from March 10th to August 30th, 1832, one proved fatal. The following is a short note of it:—

"The individual was attacked, during his stay in the hospital, with a violent erysipelas of the left hand and forearm, accompanied by violent fever and cerebral disturbance. He died the fourth day from the accession of this disease. On post-mortem examination, several large collections of matter were found in the integuments of the arm and hand; and the veins of this limb, as well as several others, were inflamed. Most of

the joints contained thick, turbid, synovia, having some specks resembling pus."

Other cases are quoted from various authors; and we presume no reasonable doubt can be entertained of rheumatism occasionally terminating in suppuration. But at the same time we must remark, that the only cases adduced by M. Bouillaud as having been witnessed by himself, are of a very unsatisfactory nature, both, and more especially the latter, being examples of those purulent deposits connected with inflammation of veins, and well described by Mr. Arnott (Medico-Chir. Trans. vol. xv.)

We now come to the treatment, and this, although the most important point of all, may be discussed in few words.

The rule of M. Bouillaud is to bleed, "*coup-sur-coup;*" and the meaning of this expression will be best understood by giving the author's formula, if we may so call it, as applied to an acute case of rheumatism in a patient of medium age, constitution, and strength.

First day.—The patient, supposed to be visited in the evening, is bled to the extent of four pallettes.

Second day.—A double bleeding of from three and a half to four pallettes, and in the interval local bleeding by leeches or cupping, the latter being preferred. By this local depletion, it is calculated that three, four, or even five pallettes are obtained.

Third day.—One general bleeding, and one local, similar to the above.

Fourth day.—The fever, pain, swelling, and other inflammatory symptoms, have sometimes disappeared. If so, no more blood is drawn; but if not, three or four pallettes are again taken from the arm.

Fifth day.—Resolution is by this time generally accomplished; but if otherwise, three pallettes are to be taken by venesection, and the same to be repeated at any time that a relapse may occur.

The average quantity of blood required to cure acute rheumatism is from four to five pounds, but in some instances amounts to seven or eight.

The auxiliary remedies mentioned by M. Bouillaud are not very important, with the exception of opium. They consist of the antiphlogistic regimen, blisters, compression, bandages spread with mercurial ointment, and lastly, cataplasms. No mention is made either of calomel or purgatives,—an omission which, in our opinion, is of vital importance. The great difference, in other respects, between the treatment recommended by M. Bouillaud and that usually adopted in this country, relates to the quantity of blood abstracted, and to the persevering manner in which the venesection is repeated. Yet does not the practice of our author differ so much as might be supposed from that formerly recommended by, probably, the greatest of English physicians; — we mean Sydenham: and we shall close the present article by quoting his own words upon the subject:—

"Ut primum accersor, statim sanguinis ℥x. è brachio LATERIS AFFECTI mitti jubeo . . . . . . Die sequenti, sanguinis tantumdem detrahi præcipio; atque intercalato die uno alterove, pro ægri viribus, tertiò; dein, interjecto trium quatuorve dierum intervallo (prout ægri vires, ætas, constitutio, aliæque circumstantiæ suadent monentque), quartò, atque ultimo ut plurimum, venæ-sectionem repeto; raró enim usu venit, ut ultrà quartam vicem venam incidamus, nisi vel regimen justò calidius præcesserit, vel medicamina calidiora ægro præter necessitatem fuerint ingesta."

An Introduction to the Study of Practical Medicine; being an Outline of the leading Facts and Principles of the Science, as taught in a Course of Lectures delivered in the Marischal College of Aberdeen. By JOHN MACROBIN, M.D., Member of the Royal College of Surgeons, Edinburgh, &c. &c.

THE first part only of this work has yet been published; it relates to the pathology and treatment of congestions, inflammations, hæmorrhages, dropsies, and fevers. We never analyse treatises which are merely elementary, but content ourselves with perusing them, and offering our opinion for the guidance of such of our readers as may be disposed to think it entitled to such confidence. On this principle we hesitate not to recommend Dr. Macrobin's book to our junior friends as one of the best introductions to the study of medicine which has fallen under our notice; it is but an "introduction," however, and can only be looked upon as containing an outline of the diseases of which it treats. Still that outline is correct, and conveys a favourable impression of the course of lectures from which it is taken.

The present is, we believe, the first work which has emanated from the Medical School at Aberdeen, and we are gratified to perceive the activity of which it constitutes an example. In many respects Aberdeen is well calculated to succeed in this respect. It has an excellent hospital, a first-rate professional library, contained in a handsome building belonging to the "Medical Society," efficient teachers in the various branches of the science, and pupils who, for the most part, have received a good preliminary education, many of them having taken their degree in arts at one of the two Colleges which the town contains.

We shall be glad to find that Dr. Macrobin extends his work to the other subjects of practical medicine.

Illustrations of the Comparative Anatomy of the Nervous System By Joseph Swan. Part I.

This first portion—of what we have no doubt will prove to be a splendid work—contains seven plates, quarto size, admirably drawn and engraved, and accompanied by explanatory letter-press. The nervous system of the crab, the lobster, the centipede, the leech, the slug, the earth-worm, &c. is displayed with a degree of clearness which we had hardly hoped to have seen attained; and the views of the sympathetic and spinal nerves of the cod are pre-eminently beautiful. We are satisfied that the publication of this work must contribute to raise the reputation of the author, high as it was already, and to place him among the first anatomists of this or any other country.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

Cicero.

EVILS OF THE PRESENT POOR-LAW, AND THEIR REMEDY.

The universal and continued outcry against the working of the amended Poor Law, proves pretty clearly that this vile and heartless specimen of legislation has not a redeeming quality about it. Time, which is said to bring a remedy for every evil, has as yet done nothing towards mitigating this: on it goes doggedly, in the manner of its outset; and every day produces some fresh examples of the malignant principle with which it is animated.

We form our judgment of the measure precisely as the Poor-Law Commissioners pretend that they are willing it should be judged. In their Annual Report, published in August last, they state, that "the change in the system has not, in many instances, been so long in operation as to develope the whole of the effects which may be anticipated from it." The four or five months which have since elapsed have served amply in the way of illustration; and we think we may now as safely form our opinion of the ultimate tendency of the system as if it had been in operation for years. All that we can anticipate from it is pure and unmixed evil for the future; while at the present, and since the introduction of the new order of things, we can see nothing in the conduct of the Commissioners but inhumanity towards the poor, and an insolent demeanour towards the profession.

That part of their report (just referred to) which relates to the medical arrangements in the several districts, is, we have no hesitation in saying, a tissue of the most paltry meanness and falsehood. Of this latter character is the assertion that they have ascertained instances in which medical men, attending the settled poor of a parish for a small fixed sum, had contrived to get upwards of three hundred pounds a year by treating paupers of other parishes under suspended orders of removal; and that this system was the result of a sort of collusion between the parochial surgeons and overseers! This gross charge is made without an atom of proof in the shape of evidence; it has been again and again contra-

dicted by trustworthy and indignant parties: the Commissioners have been called upon, directly, or indirectly (through the anonymous officials who sometimes venture to echo them in the public prints), to adduce specifically, and to point out those instances individually, upon which they ground a statement so derogatory to a large and respectable class of the community. But no; this would be too great a mark of condescension, or, more probably, it would lead to unpleasant explanation; and so it has been permitted by the worthy functionaries and their retainers to pass *sub silentio.*

There are two points connected with the new Poor Law measure which cannot be too frequently adverted to and dwelt upon. The first is, that the tenure of office by the Commissioners subsists on the condition that savings shall be effected at all risks, and that the starving and sick poor shall be tested to the uttermost, in order to find out upon *how little* relief they may contrive to keep soul and body together. The second point to be kept in view is, that the avowed notion of the authors of the *amended* Poor Law is, that by adopting a rigorous and severe system in dealing with the poor, pauperism may be eventually seared away, or abolished totally: by affording no indulgence, and as little countenance as possible to the sick and hungry, they hope—and with very good reason—that there will be no sick or hungry at last to relieve: disgust and despair, they are confident, will aid their cause; and it is only natural to conclude that they calculate also on another worthy agent equally effectual in assisting them—death!

This odious manœuvre of goading the unfortunate to desist from soliciting parish relief, we perceive, is steadily kept in view by the Commissioners; but, as might be expected, their only mode of upholding it in principle is by a sophistry which would be beneath contempt, were it not for the dangerous consequences to which it leads. They find out, for example, that by pursuing their plan, a few persons who hitherto availed themselves of parochial medical attendance, while they could very well afford to pay for it, have now abandoned their claims. One of the new contract-surgeons is brought forward to vouch for this notable fact: he says, in his evidence, that he has met with many cases of the kind, and cites *one* instance. Thus, then, because the practice of relieving the poor, under the pressure of their wants and bodily infirmities, has been found liable to abuse, it must be abolished altogether. Because impostors sometimes succeed in extorting the charity of the benevolent, the really necessitous shall no longer have assistance; because there are malingerers abroad, and persons who feign diseases, therefore there shall be no medical relief. Such is the sort of argument, if it be not the identical one, with which our sapient and humane New Poor-law functionaries amuse the public, and establish their right to the enjoyment of their ample salaries.

But the public must be very obtuse indeed, if it cannot see and appreciate what is daily passing before its eyes. Take the recent affair at Thatcham as an example. The new system was exhibited there in its true colours, and with all its native inhumanity thick upon it. The life of a wretched man was sacrificed for want of that medical assistance which ought to have been supplied by the Guardians (as they are miscalled) of the Poor. The circumstances must be fresh in the recollection of the reader; the newspapers contained the details, shocking as they were, elicited at the coroner's inquest. A man, in a dangerous and (as it proved)

fatal state, was removed in a cart a distance of some miles, and seen *but once* by the contract-surgeon (and that after grievous delay) during the last two or three days preceding his death. All this, as well as the general mischief attendant on the system, was abundantly exposed at the inquest, and stands confirmed by the verdict of a respectable jury.

Nor has the sequel of this lamentable affair been less disgraceful to the same parties. The coroner and foreman of the jury waited on the Board of Guardians to make remonstrance on the evils complained of, and to suggest remedy and redress. But the result of the mission was as might have been anticipated: there was no redress nor relaxation of the usual haughtiness. The all-sufficient functionaries hesitated not to act as advocates and judges in their own cause. The jury, on their oaths, found that there was a culpable negligence and insufficiency in respect to the medical attendance yielded to the deceased: the Board, at their leisure, announced that *they* found no such thing—the medical attendance was what it ought to be—and that if the man died, it was no fault of theirs.

There is but one way of dealing, that we can see, with these insolent personages. They are not amenable, indeed, to the power of a coroner; nor do they seem in the slightest degree affected by the influence of public opinion. One tribunal, however, is still open; and we are greatly deceived if the evidence already accumulated have not its due weight in the quarter to which we allude. Parliament meets presently; let petitions be prepared in strong and respectful language, praying the interference of both Houses to prevent the abomination of further proceedings under the New Poor Law. Let it be urged that that law—or rather the *amendments* (so called) introduced into it—and the practical results of which are found to be so iniquitous, shall be repealed, and a more suitable and salubrious system adopted. Then, and not till then, can we expect any change for the better: but *until* such a step have been duly taken, and have failed, we can see no reasonable ground for despair.

PROCEEDINGS OF THE PANTON-SQUARE PHILOSOPHERS.

SKULLS FROM THE MAURITIUS.

Dr. Stewart, a medical officer at the Mauritius, lately sent to Sir James Macgrigor four skulls, requesting that they might be handed over to the Phrenological Society here, for the purpose of obtaining the opinion of that learned body as to the characters of the individuals from whom they had been taken. With them was transmitted a sealed packet, which was to be retained at the Army Medical Board in Berkeley-street, until a written statement of the result of the phrenological examination was forwarded from Panton Square.

The Society, as a body, rather knowingly, declined the proposal; but Dr. Elliotson undertook the task, and forwarded his opinion to Sir James Macgrigor, as required. The sealed packet was then opened in due form, and with the following result. We ought to remark that the skulls and the characters of the individuals were labelled with corresponding numbers. Of Nos. 1 and 3 nothing is known, and they were probably added only as a further test for the phrenologists; but the skulls of No. 2 and 4 belonged to remarkable personages.

Of No. 2, Dr. Elliotson's estimation runs thus:—"Might have been undistinguished in talent, though possibly quick of observation; but proud, quarrelsome, selfish, and sly."

The written packet informs us that "this man, a negro slave, was tried on the charge of having murdered one of his comrades, and tried and convicted of a barbarous attempt to murder another, a female, upon the very slight provocation of accusing him of having stolen a pair of scissors." He was also "sly and cunning," and so far Dr. Elliotson's guess is pretty good, though the degree of ferocity displayed by a double murder is greater than the mere term "quarrelsome" would imply. But three

of the most conspicuous points in the character—namely, jealousy, lust, and intrepidity—are not even hinted at. "He was extraordinarily jealous, (says the packet) and while under the influence of jealousy, quickly rendered ferociously irritable, most abusive in language, and violent in acts. The attack on his first victim was caused by slight attentions shown to his comrade, by his master, for good conduct." And again, as to his measureless lasciviousness, "he was most libidinous in temperament; two examples of the disposition are striking. He made indecent propositions to a person in a class very highly above him; and only a few hours before his execution, on being kindly asked by his spiritual attendant whether he wished to have any thing, he answered, 'Yes, a woman.'" Neither is any phrenological notice taken of his reckless boldness. "His intrepidity amounted nearly to insensibility at the place of execution; he mounted the scaffold boldly, examined the axe, talked freely to the executioner, and laid his head on the block without a sign of fear."

It is proper to add, however, that afterwards it was remarked by the Society, and assented to by Dr. Elliotson, that "mativeness" was very large in the skull; but this, as an *ex post facto* discovery, is good for nothing.

Come we now to No. 4; concerning which Dr. Elliotson's summary is, "*May have been, in every respect, a highly respectable character, though of ordinary intellect.*" We shall give the biographical sketch of this "highly respectable character," from the packet, without a single comment:—

"No. 4 is the skull of Rhugoburg-Sing, an Indian, who was convicted in India of killing one man and wounding two others, under circumstances unknown to the writer of this note. He was transported to Mauritius, and was for some years employed there as a convict. He was violently ferocious, and had a strong propensity to destroy. Some time back he was tried, for having, almost without provocation, knocked down two men with a staff, nearly killing one of them by fracturing his skull. He escaped on the trial through an informality. He was afterwards convicted and executed for a murder, supposed to be committed in revenge for an insult offered to the family of the culprit, who was of a high caste. His behaviour immediately after condemnation was brutally savage, but he afterwards became more quiet, and died courageously. He seemed irritated at his sentence, because no one saw him commit the act. He endeavoured to escape, and severely stabbed two persons who were employed to take him."

In this dilemma, Dr. Elliotson at once adopts the obvious and most satisfactory explanation, that "as phrenology is true," the numbering must be false; in short, that packet No. 4 did not belong to skull No. 4; and as the gentleman by whom they were furnished, himself "a zealous phrenologist," has been written to on the subject, we have no doubt the mistake will be rectified with the least possible loss of time.

SKULL OF SWIFT.

At the second meeting for the season, the Society was entertained by a Mr. J. I. Hawkins, with a critique on an article of ours. How proud we ought to be! But though the gentleman brought to his task an abundant quantity of phrenological zeal, we must say he displayed a marvellous lack of information and candour *. In order to prove that Dean Swift possessed Amativeness "large," Benevolence "small," Ideality "small," Wit "small," &c. &c. by way of gainsaying our assertions to the contrary, and which we derived from the most authentic sources, Mr. Hawkins raked the puddle of the libellers of Swift's character, and thus eked out the principal portion of his paper.

For example, he finds that Dr. Beddoes, in an essay in his Hygeia, throws out some conjectures on the probable cause of the Dean's vertigo, which the Doctor attributes to certain "habits of early and profligate indulgence." This Mr. Hawkins takes for "confirmation strong" of Swift's *amativeness*; though he must know that Beddoes had not an atom of proof of the real existence of any such habits as he indecently and most disingenuously imputes to the Dean. We say that Mr. Hawkins must know this; for he borrowed the quotation from the very page of Scott's life of Swift in which the passage is both cited and censured in terms of indignation by the biographer. Sir Walter, having shewn, in disproof of Beddoes'

* We refer for further particulars concerning the matter of this article, to Dr. Macleod's letter, at p. 543.

assertion, that the gross images indulged in by Swift were the very reverse of the licentious or amative, adds a remark which will apply to certain medical phrenologists, as well as to him for whom it was originally intended—"Until medical authors can account for and radically cure the diseases of their contemporary patients, they may readily be excused from assigning dishonourable causes for the disorders of the illustrious dead."

But again, Swift's *benevolence* was "small." How is this point made out for the satisfaction of the phrenologists? By having recourse, in contempt of Scott and all the best biographers, to the notoriously malignant and disgraceful article on Swift which appeared in the Edinburgh Review in the year 1816. Mr. Hawkins also quotes a hearsay story, which he picked up in a recent visit to Dublin, to the effect, that the Dean used sometimes to institute legal proceedings against persons to whom he had *benevolently* lent money: of this, says Mr. H., "I was informed in Dublin as a notorious fact." Poor simple critic! Did he really think he met any one in Dublin who could give him better information on this point than is contained in the biographies of Swift?

Will it be believed, also, that our phrenologist cites, in proof of his position, that the Dean had *ideality* "small," the well-known remark of Dryden, who, when Swift, then a mere boy, presented him with a copy of verses in the shape of an ode—"Cousin Swift, you will never be a poet?"

And again, to show that Dean Swift possessed *causality* and *comparison* only in a "moderate" degree, as the "organs" of the skull indicated, our critic quotes Scott, where he informs us that logic was a distasteful study to Swift in his College days: but Mr. Hawkins ought to have recollected that a hatred of Burgersdicius does not necessarily imply a deficiency of the reasoning faculty: even Locke himself had no great attachment to the logic of the schools.

But we have bestowed more notice on the silly and shallow performance of our critic than it deserves. In our original article on what appeared in the Phrenological Journal concerning Swift's "*developments*," we proved that either the skull which the philosophers in Dublin had got hold of was not Swift's skull, or that phrenology was an impudent lie. Mr. Hawkins has laboured heartily to affirm the former position, but he has failed to extricate his beloved phrenology from the other horn of the dilemma.

We may as well append, for the benefit of Mr. Hawkins and the phrenologists generally, the remarks which appeared in the *Times* of Wednesday last, on the same subject as the foregoing: they may serve, along with our own observations, to furnish another evening's entertainment for the frequenters of Panton-Square:—

"Dull witted and half-educated men always seek some by-way of notoriety, having just sagacity enough to discover that they have no chance of acquiring any reputation in the regular field of art and science. Among the most offensive of these quacks may be classed the phrenologists, or bumpologists, as they are more appropriately called. Every body knows what blunders these blockheads made over a supposed skull of Raphael, which turned out to be the skull of a grave-digger: and we have already noticed some impertinent trash which has been poured forth respecting the skull of Dean Swift, which was pulled from the body, and subjected to the scrutiny of these pedantic dunces. We see, in more than one quarter, that this disgusting folly is still at work: we cannot waste our time, nor that of our readers, by any detailed exposure of the absurdities which have been published, but we give one specimen as a decisive sample of the rottenness of the bulk. These worthies, then, have discovered, and are ready to prove, by the size of the "organs of wit and ideality" in Swift's skull, both "small," to adopt their jargon, that the world must be totally mistaken about the Dean of St. Patrick's; and that the author of the ***Tale of a Tub*** and *Gulliver's Travels*, had neither brilliancy nor originality! And there are gaping simpletons who swallow these crudities, and call them science."

A LAST WORD TOUCHING THE CHAIR OF SURGERY IN EDINBURGH.

A NOTICE in the Lancet of this day (January 2d) confirms all we have said in reference to the absurd puff about the Surgical Chair in Edinburgh having been refused by Mr. Liston. We conjectured that some unauthorized indi-

vidual had asked Mr. L. to become a candidate, and he, knowing how matters stood, very wisely said he would not. It now appears that a Mr. Dick was the individual. "*This* is the whole of the matter."

INSURANCE OFFICES.

FEES FOR CERTIFICATES: WHO OUGHT TO PAY FOR THEM?

To the Editor of the Medical Gazette.

Sir,

I am induced, by your leading article of last week, to address a few observations to you on the interesting subject discussed in it.

After carefully weighing all you have said, I am still not convinced that a medical man has any just claim on an Insurance Office, for certifying respecting the health of an individual whom he has attended, or with whom he is acquainted, and who refers the Office to him for a testimonial as to the insurability of his life.

The case, when divested of all unessential considerations, appears to me to stand thus:—An individual, for his own purposes, wishes to insure his life: the Office to which he applies, says to him—We will insure you on these conditions: first, that you will present yourself to our examining Physician or Surgeon, and satisfy him as to your actual freedom from obvious disease, and your healthy and unexceptionable appearance:—Secondly, you must arrange with your ordinary medical attendant, or some professional person who has a sufficient knowledge of you to enable him to give an opinion on the subject, that he shall answer such questions as we may think it necessary to put respecting your past state of health, and the general habits and predispositions of your constitution, with a knowledge of which a mere inspection by our own physician cannot supply us. If you will do this, and if we are satisfied with your appearance, and with the answers given by your medical referee, we will insure your life; if not, we decline insuring you.

Now, in this case, as it appears to me that the medical man answers the questions for the sake of his patient and employer, who, without his testimony, cannot get insured, whatever remuneration he may think due to him, should, in my humble judgment, be claimed not from the Office but from his patient, who is, in fact, virtually though not actually, the asker of the questions.

Besides, supposing the medical man refuses to answer the questions; whom, I would ask, does he chiefly disoblige? not, surely, the Insurance Office, for in such a case the Office refuses the life, and there is an end of the matter as far as they are concerned; they have one insurance less, which might or might not have turned out an advantage to them; but it remains for the medical man to account to his patient for not doing what he requests him to do; and without which, he was told by the Office, from the commencement of the affair, that his life could not be insured. He it is who by such refusal has lost the opportunity of making an advantageous purchase, or a marriage-settlement, or a provision for his family; and he must settle the matter between his medical attendant and himself.

The case of one individual insuring another resolves itself into the same elements, *mutatis mutandis*, as the above, and therefore need not be dwelt upon.

I have argued this question on the supposition that a fee ought to be offered to and accepted by a medical man who writes a certificate for his patient; it being only a doubt, when such certificate happens to relate to the insurance of his life, from what quarter the fee ought to come to him: I trust, however, I may be allowed to say, without giving offence to those who may differ from me on this head, that I was early advised by an eminent professional friend, now no more, to decline altogether taking any remuneration for certificates, and I have always acted on this principle, not because I suspect myself, or suppose that others deliberately suspect me, of being capable of receiving a bribe to testify to a falsehood, but because I would place myself, if possible, above even the insinuations of a hostile advocate, should the matter to which the certificate refers be at any time disputed in a Court of Justice; for I think it cannot be doubted, but that the receiving of a fee for such a duty depreciates to a certian extent the document itself as a disinterested testimonial, in the eyes of the vulgar, and it is with the vulgar we generally have to do in such cases. This, however, I am aware is not exactly the

question at issue; I will not, therefore, occupy your time by saying any more respecting it.

With regard to the promises made by some of the Offices to medical men, that their answers will be considered confidential, I would join you in reprobating it in the strongest terms—We neither ask nor want their confidence. In answering correctly the questions put to us, we are merely acting the part of honest men, and the only return we can claim, as a matter of confidence, for our disinterestedness and candour, is that our opinion should not be wantonly or unnecessarily divulged; or divulged at any rate in such a manner as should disturb the mind of our patient, and place us in an uncomfortable posture with respect to him. More than this they cannot honestly promise us, unless our certificate is to be considered a dead letter.

I quite agree with you also as to the unreasonable demands for gratuitous labour that are frequently made on the profession, especially by the government or the public, who have certainly no more right to call on us to transact their business without adequate remuneration, than they would have to ask an attorney or a barrister to prepare briefs and plead against felons for the mere satisfaction of performing this useful duty. All I contend for is, that the duty of granting certificates for the insurance of lives is not quite a fair illustration of your position. I am, sir,

Your obedient servant,

MEDICUS LONDINENSIS.

Dec. 28, 1835.

CLINICAL LECTURE

ON

TIC DOULOUREUX, OR FACIAL NEURALGIA,

Delivered at St. George's Hospital, Dec. 15, 1835;

BY SIR BENJAMIN C. BRODIE.

"JOSHUA KINGETT, 48 years of age, was admitted into the hospital on the 14th Oct. 1835. On his admission he stated that for the last ten months he had been suffering the most severe pain, which was entirely confined to the left side of the face; that this pain at first had an intermittent character; but that latterly it had become constant; and at times was so acute that, to use his own language, he would have rejoiced if any one had knocked him on the head. At these times he seemed almost to lose the sight of his left eye, and very often suffered from tooth-ache. At the time of his admission the pain was chiefly confined to the cheek and nostril, which were puffy, and tender to the touch. There was no disease to be observed on looking into the nostril. The bowels were always torpid, and the tongue was covered with a whitish-brown fur. He was directed to apply the veratrine ointment, in the proportion of a scruple of the veratrine to an ounce of lard. A portion of this was to be rubbed in twice a day, and he was to take five grains of blue pill every night, with a draught containing five drachms of infusion of senna, five drachms of compound infusion of gentian, a drachm of tincture of senna, and a drachm of sulphate of magnesia every morning.

"On the 23d, having pursued this plan for about week, he thought that he was a little better. A bad tooth was discovered in the upper jaw, which was extracted. The tongue was a little cleaner He was directed to take infusion of rhubarb and columbo, of each six drachms, with a drachm of compound tincture of cardamoms, and half a scruple of carbonate of potass, three times daily. He was to go on taking the blue pill."

On the 29th the report runs thus:—"He has improved rapidly; the pain is now very tolerable; the bowels are open twice daily; the tongue is nearly clean."

On the 7th November it is said, "The pain, which had almost left him, returned with great severity two days ago. He has had no sleep since, in consequence of it. The tongue is again white and furred. The medicine was not sufficient to act on the bowels, which have been confined for the last two days. He was directed to take five grains of blue pill every night, and a dose of compound infusion of senna with sulphate of magnesia every other morning."

On the 15th it is said that "he had been again relieved as soon as the bowels were well opened."

On the 17th November I placed him on the following plan of treatment. He was to take five grains of blue pill, five grains of compound extract of colocynth, with three grains of extract of lettuce, every night. This medicine acted well on his bowels; he has been purged ever since he took it, two or three times daily. He has continued to take it up to the present time. The tongue is now quite clean. He is entirely free from any thing that deserves the name of pain, although he has

still some feeling of uneasiness in the face."

A violent pain in the face attacking the patient at intervals,—a pain so violent that the patient wishes that somebody would destroy him, and yet there being no disease perceptible in the parts to which the disease is referred: it is to a pain of this kind that we commonly apply the name of *tic douloureux*, or as some call it, with more propriety, *facial neuralgia.* We must regard this case, then, as one of tic douloureux, or, if you please, facial neuralgia.

You will observe, that besides other classifications which you may make of the pains that occur in disease, you may divide them under these two heads. There are cases in which the pain is felt where the disease exists, as there may be inflammation in the knee, and pain in the knee in consequence; carcinoma in the breast, and pain in the breast in consequence; disease in the liver, and pain therefore in the hepatic region. Then there are other cases in which the pain is referred to parts which are not actually the seat of disease. Thus, there may be pain in the knee while the real disease is in the hip; there may be pain in the shoulder while the real disease is in the liver; there may be pain in the breast, while the real disease is an hysterical state of the constitution generally.

Tic douloureux, or facial neuralgia, belongs to this last class of pains. The pain which is felt is referred to some part or other of the face, or to the whole of one side of the face, and yet there is no disease there. You are not to suppose that the cause of the pain in this complaint is always the same: the fact is, the pain is but a symptom, and it may depend upon different causes; so that in those patients who are said to be affected with tic douloureux, the real nature of the disease varies very much in different cases. You may have half a dozen persons with tic douloureux in the face, the symptoms in all of them being the same, or very nearly the same, and the real disease may be different in every one of them. The pain, as I have said, has the same character in all these cases, and it differs from the pain of most other nervous affections. You will observe that the branches of the fifth pair are all under particular anatomical circumstances; that they all proceed from that remarkable plexus which is bathed, as it were, in the blood of the cavernous sinus, and that the branches of it all run through bony structures; the second and third branches especially being enveloped in bone to a great extent; and probably it is from one or other of these anatomical circumstances, or from both of them combined, that the pain derives its peculiar character.

The pain in all these cases, whatever may be the cause of it, generally comes on gradually. At first it is a pain which, though severe, may be borne; but at last it becomes quite intolerable,—so intense that the patient always says he would rather die than bear it. At first he complains of an odd twinge every now and then in the face; and it generally begins in the cheek where the second branch of the fifth pair of nerves is distributed. The twinge becomes more severe, and recurs more frequently. At first it recurs only two or three times daily, and lasts for an instant; then the twinge becomes more severe, of longer duration, recurring several times in the twenty-four hours; and so it goes on increasing. When the disease is at its height, the patient is in as wretched a condition as you can well imagine a human creature to be in. The pain attacks him every quarter or half hour, sometimes oftener, coming suddenly and unexpectedly on him at uncertain intervals. He states that at first here is a sensation of spasm, which is followed by a violent and continued pain, accompanied in some cases with a sense of pressure acting from above. You see the patient acting with all the muscles of the trunk, as if it were necessary that he should make this effort in order to support himself under a heavy weight that was forcing him to the ground. This will last perhaps for two or three minutes, and then the pain goes off, and he is quite well again till the attack returns. The recurrence of the pain is always readily induced by the patient's attention being directed to it. If you ask him how his face is to-day, the attack comes on directly; but if you hold him in earnest conversation upon any other subject, it may stay away for half an hour. The patient often cannot get to sleep on account of the pain; but having once fallen asleep, he may continue so without the pain recurring for several hours. I have known this to happen even in the very worst ca es.

When the pain comes on there is often violent spasmodic contraction of the muscles of the face; and perhaps it is this which causes the face, on the side on which the disease exists, to become swollen and puffy. The conjunctiva of the eye on that side looks red and blood-shot. The pain, I say, generally begins in the cheek; and often it is altogether confined to the parts to which the second branch of the fifth pair of nerves is distributed; but in extreme cases it will sometimes extend to the forehead, that is, to the parts supplied by the first branch of the fifth pair of

nerves; and to those supplied by the third branch of the fifth pair, that is, to the chin, and even to the teeth. In some cases the tongue and palate are affected also.

In some cases the disease torments the patient for a month, six weeks, or even six months, and then, without rhyme or reason, vanishes, and he continues well for an uncertain period: then it recurs, and continues as long or longer than before. In other cases the disease may vanish, not for a time but altogether, the patient obtaining a complete recovery. In other cases, again, there is never an actual giving way of the disease; it goes on tormenting the patient day after day, month after month, year after year; and in some of these cases other symptoms ultimately supervene, and the disease proves fatal. But of this I shall speak again hereafter. In addition to what I have already stated, it is worthy of notice that the disease attacks only one side of the face; I never saw it in both sides.

On what cause do these symptoms depend? Many persons thus affected have a bad tooth, and they generally go and get it drawn, it being thought that the carious tooth may be the cause of the pain. I never knew a case myself where the patient was relieved of genuine tic douloureux by the extraction of a carious tooth; and I remember that in a conversation which I had some years ago with a very experienced dentist, he told me that he had frequently been called upon to draw bad teeth where the patient had laboured under tic douloureux in the face, and he could not remember that the operation had ever been of any service. I have said that the disease may depend on different causes. Sir Henry Halford has published a paper, in which he mentions some cases bearing all the character of genuine tic douloureux, in which the symptoms seemed to be connected with a diseased condition of the bones of the face; and I have no doubt that such is their origin in some instances. There was a man in this hospital suffering from a pain in the face and cheek, having all the characters which I have just endeavoured to describe, and in whom there was disease of the bone of the upper jaw. If I remember right, for I have preserved no notes of the case, he went through a course of sarsaparilla; a portion of the bone exfoliated, and after this the pain was very much relieved. I saw another case where there was pain very like that of tic douloureux existing in combination with disease in the bones of the upper jaw, but of which I know not the result. But these are rare instances. There is no diseased bone to account for the pain in ordinary cases. Then from what else may it arise? You will find it sometimes in young women of hysterical constitution, a product of hysteria. Where there is hysterical pain referred to the part in which the branches of the fifth pair are distributed, it assumes the form of tic douloureux. Then at other times the pain is intermittent and periodical, depending on that peculiar state of the system which may produce the phenomenon of ague, and may be cured as ague is cured, by quinine or arsenic. In other cases, again, the disease evidently depends upon the state of the digestive organs, and the patient is cured by great regularity as to diet, and a course of medicine which is calculated to put the digestive organs into a more healthy condition. In another order of cases, the pain in the face is the result of disease in the brain. The late Dr. Pemberton, who was for many years physician to this hospital, and was engaged in a large practice at this end of the town, in the midst of his career of prosperity became affected with tic douloureux, and suffered from it in the most horrible manner. I never saw any individual, under any circumstances, suffer more. He went into the country, and died with symptoms of disease in the brain.

There was a gentleman who had tic douloureux in the face for a very long time. The pain at last left the face, and then he was attacked with fits of epilepsy. As the pain left the face when the patient became affected with epilepsy, that alone seemed to be sufficient ground for believing that there was some disease in the brain. After that, however, there was a ptosis, or a dropping down of the upper eye-lid, on the same side on which the tic douloureux had existed. After a more than usually severe epileptic fit, he fell into a state of apoplexy, and died. Mr. Green, Mr. Freeman, and myself, who had attended him, examined the body after death. We found all the membranes of the brain bearing marks of chronic inflammation; the vessels connecting the *dura mater* and the bone unusually large; the *tunica arachnoides* thickened, and at the upper and back part of the left hemisphere of the cerebrum adhering to the inner surface of the dura mater, in a spot about an inch in diameter. The cerebrum generally was soft and vascular, exhibiting a red mottled appearance on many places. The softening of its substance was most distinct in the crura cerebri, fornix, and adjacent parts. The nerves of the fifth pair were carefully dissected to the extremity of the cavernous sinus, but presented no morbid appearances.

There are still other cases in which you cannot trace tic douloureux to its real source. There is something or

other somewhere or other in the system, which acts as a source of irritation to the nerves of the face; but where that something is, and what it is, we cannot discover. Indeed, generally speaking, I should say that nothing is more difficult than to trace any local nervous affections to their real source. The disease may be in one part of the body, and the pain or spasm which it produces may be in another. I have known a patient have violent neuralgia of the foot, which depended on a stricture of the urethra, and which, whenever it occurred, was invariably relieved by the use of a bougie. I have known another patient have neuralgia of the foot depending on internal piles, which came on when the piles were protruded through the anus, and went away when they were reduced. I have known a spasmodic wry neck, or a nervous pain in the back, to alternate with insanity.

If it were worth while to do so, I might mention other cases illustrative of this observation, that the disease may be in one part of the body, and, from some nervous connexion, it may produce pain in some other part of the body. We cannot explain the matter much further than this. I may, however, venture to make this additional observation—namely, that there is good reason to believe that the seat of the nervous communication, on which those sympathies depend, is for the most part not in the nerves themselves, but in a higher place—in the brain, or in the spinal cord.

Treatment.—The treatment of *tic douloureux*, of course, must differ in different cases. In some instances it may be relieved by one method; in others, by another; but in the greatest number of cases it cannot be relieved at all. A very old operation, which had fallen into disuse, but has been revived of late years—namely, that of dividing the trunks of the nerves, to the extremities of which the pain is referred. It has been said that if the pain be referred to the extremity of the second branch of the fifth pair of nerves, you should divide the second branch where it passes out of the infra-orbitary foramen on the face; that thus you will cut off the communication between the extremities of the nerve and the brain, so that the painful sensation may no longer be communicated to the sensorium. Now this would do very well if the seat of the disease were really in the extremity of the nerve; but there is no reason to believe that it is so, and there is every reason to believe the contrary.

The irritating cause, whatever it may be, manifestly acts not on the extremity of the nerve, but on its origin; and both reason and experience prove that the division of the nerves below the origin is of no service. I have myself performed this operation without the smallest benefit to the patient.

In the late Dr. Pemberton's case the branches of the nerves were divided by Sir Astley Cooper. Sir Astley did not recommend it, and, if my recollection be accurate, when Dr. Pemberton first applied to him to do it, he declined acceding to his wishes. He did it at last in order to satisfy the patient; but the division of the nerves, instead of giving relief, very much aggravated the evil. It is altogether an unscientific operation, from which we have no more right to expect any benefit than we should have if we were to amputate the testicle, because pain was referred to it in consequence of a calculus being lodged in the ureter.

In those cases in which the disease has an intermitting and periodical character, you can always relieve it, as you may all other cases of intermittent and periodical disease, by the exhibition of quinine, bark, and arsenic. But then, if you give quinine, it must be in large doses; you must begin with ten grains, and go on increasing it. I saw this very morning a gentleman who had formerly a nervous pain in the back, almost as bad as tic douloureux in the face. It was intermittent and periodical. I told him, when he consulted me about it, that I was sure that quinine would cure him. He took ten grains without benefit; he took twenty with little benefit; and was not cured till he took half a drachm daily. He remained well for two or three years afterwards. The combination of bark and arsenic, also, is an excellent remedy in these cases of intermittent and periodical disease; but I generally prefer giving quinine first, because it is a more innocent medicine, requiring no watching, and not subject to the inconveniences which belong to the use of arsenic.

I was consulted, in conjunction with another practitioner, concerning a young lady who had tic douloureux of the face. She was hysterical, and the disease had followed the occurrence of some circumstances which had occasioned great agitation of mind. The case was evidently connected with hysteria and an irregular state of the menstruation. We gave her steel and ammonia in combination, which put her into better health, and in the course of a few weeks the tic douloureux, which had existed for many months, had disappeared.

If you can really trace the pain to disease in the bones of the face, you must of course, instead of directing your attention to the pain which is the symptom, endeavour to cure the disease in the bone which

produces it. A piece of bone may exfoliate; and if the dead fragment has caused the pain by pressing or otherwise irritating the trunk of a nerve, the pain may thus be removed; or perhaps the patient may get well under the use of sarsaparilla, which, as you know, acts most beneficially in a number of cases of disease of the bones; or if sarsaparilla fail, you may serve your patient by the exhibition of calomel and opium, oxymuriate mercury, some preparation of iodine, or the mezereon; every one of which may in its turn be advantageously resorted to in cases of disease of the bones.

In cases where the pain depends on an organic disease of the brain, you must of course turn your attention to the primary affection, although it is probable that in the majority of these cases you will be able to render the patient but little real service.

But supposing that you can trace the disease to no other source, and that you find the tongue furred, the bowels confined, and other indications of an ill performance of the digestive functions, you have a right to conclude that this very probably is the origin of the pain in the face; at any rate you are called upon, in the first instance, to ascertain what will be the result of putting the digestive functions in better order. It was upon this principle that I proceeded in the case to which I called your attention in the beginning of the lecture; and you see that the practice has answered so far wonderfully well. As the bowels were opened, and the tongue became clean, so the pain abated. A great number of diseases depend on the state of the digestive organs. You will meet with examples of this every day; and there is nothing more remarkable in a patient having tic douloureux from a deranged state of the digestive organs, than there is in having sick headache in consequence of an overloaded stomach, or a lumbago from costive bowels.

But supposing that you cannot trace the disease to its real source,—that the patient is in other respects well,—that all the functions are well performed,—that there is this frightful pain, and you have no clue to lead to the real seat of the original malady, and therefore no clue to the practice you ought to adopt,—you are driven to the expedient of trying remedies at hazard,—a very unsatisfactory mode of proceeding, it must be acknowledged, but you have no alternative. You may give the patient quinine, which is useful in many cases of nervous pain, even though it be neither intermittent nor periodical; or you may give carbonate of iron, which I do not hesitate to say relieves many neuralgic affections also. Half a drachm of the carbonate may be given three times a-day, and the dose may be gradually increased to a drachm. I never saw any good arise from pushing the use of the carbonate of iron beyond this; and I can easily conceive that much evil may arise from its being given in those enormous doses in which, if I am rightly informed, it is given by some practitioners. It is easy to conceive that when thus exhibited, the bowels may be actually clogged by it, just as in other cases they are found clogged by cubebs or by Ward's paste. Whenever you give these insoluble substances, you should give an occasional purgative, to prevent the accumulation of an insoluble mass in the bowels. I heard of a patient who died of inflammation of the bowels, in consequence of taking large doses of cubebs, which were not purged off. So I can conceive that inflammation of the bowels may be produced by the large doses of carbonate of iron being suffered to accumulate in the intestines.

If the quinine and carbonate of iron fail, it may then be worth while to try the effect of zinc or copper, or some of those other metallic salts which are occasionally useful in cases of chronic nervous affection.

But supposing that you have tried all ordinary means without benefit, are you to go on *ad infinitum* tormenting the patient with medicine? The first rule of our art is to do no harm; and if you have tried all reasonable expedients without benefit, you had better not go on to further experiments. No one can be dosed constantly with medicine without the health being injured by it, ultimately, if not immediately; and if you have not some reasonable grounds for giving medicine, you should not run the risk of doing harm by its continued exhibition. It is much more wise and honest, when you do not know what to do, to advise your patient to wait, and take the chance of the pain subsiding of itself, as it does in many instances. But where you cannot cure your patient, you may often succeed in making his life less intolerable than it would otherwise be. Some patients are capable of being much relieved by the use of opium, and among them there are a few with whom opium never disagrees, so that they may take it without harm. Even in these, however, it should be given only when the pain is more than usually severe. Let them avoid taking it constantly, because then the opium loses its effect. In slighter cases, the patient may perhaps be benefitted by ext. of lettuce, ext. of henbane, or some other of the slighter narcotics. In all cases the patient is likely to derive advantage from avoiding

as to diet, and mode of life in other respects, irregularities, including all unusual demands on the nervous system, great mental exertion and anxiety.

In the present case, one of the first things which I did was to direct that the part should be rubbed with the veratrine ointment. This has been lately proposed as a remedy possessing a most extraordinary influence over a number of diseases, neuralgic affections among the rest. I saw one patient who thought himself relieved by it of a pain in the forehead, connected with disease of the frontal bone in the neighbourhood of the frontal branch of the fifth pair of nerves. I was, however, by no means satisfied that the relief really arose from the use of the ointment; and in several other cases I have had recourse to it without the smallest advantage: however, there could be no objection to the use of it on this occasion, and I thought it worth while to make one experiment more—you have heard the result.

Although I employed the veratrine ointment in this instance, I am not one of those who would be trying indiscriminately all the new remedies which, in these days, are being constantly brought before the public; nor can I think well of this modern fashion of resorting on all occasions to novel methods of treatment. I see many practitioners who would always rather give a new medicine than an old one, but I advise you, if you wish to succeed in your profession and to be useful to the public, to pursue a different course. Make yourselves masters of the old remedies. Learn how to handle them, and what good they will do, and as a general rule, have recourse to them in the first instance. If the old remedies fail, and you are at a stand-still, then, and not till then, have recourse to the new ones. If you always begin with new remedies, you throw away all the valuable results, not only of your own experience, but of the experience of those who have gone before you. You have to begin, as it were, *de novo*, and the first consequence of this will be that you will not cure your patients; and the second, that you will have none to cure. Where old remedies fail, I say that it is not only not unreasonable, but proper, that you should ascertain what can be done by new ones; but it is very unwise to employ the latter, where there are sufficient grounds to believe that those already in use will answer the intended purpose. I should be very sorry to see the march of science impeded by an unjust apprehension of experiments and innovations; but, surely, there is a broad enough line between a discreet and prudent use of new remedies, and that indiscreet and hasty use of them which we find to prevail in the practice of the medical profession at present.

PAROCHIAL SURGEONS AND THEIR VILIFIERS—

THE DEFENDERS OF THE NEW POOR LAW SYSTEM.

[We give insertion to the following letter (from the *Times*), as it was partly promised by our correspondent, Ruricola, in his last communication to us.]

Sir,

In your paper of the 28th of November I read a letter from a guardian of the poor, signed "Rusticus," vindicating the arrangements of the poor law authorities in the matter of medical relief.

As this is, I believe, the first public attempt to defend what is so generally considered to be indefensible, I looked with care through his communication for arguments in support of his views. I was, however, surprised to find that it contained nothing but a quotation of regulations which were already sufficiently well known, an unauthorized contradiction of authorized statements, and an unwarrantable attack on a large body of men whose characters, fortunately, stand too high to be injured by his representations.

With regard to his first point—viz. "that medical men are bound to attend on all sick paupers resident within the union," and his assertion that "medical men very generally have wished to interpret this as relating only to those on the parish books," I can affirm, from a much more extensive acquaintance with the opinions of general practitioners than it is possible that "Rusticus" could obtain, that they do not wish so to interpret this clause, but are glad to take it in its literal meaning; that it is regarded by a large majority of the profession as a most desirable preventive to the vexatious and injurious mode of attendance on extra parochial poor formerly in vogue; and that, so far from their craft being in danger, they are well satisfied that that practice, extremely troublesome in its nature, and uncertain in its remuneration, should be abolished.

The insinuations of the Poor Law Commissioners, and the bold assertions of "Rusticus," as to the profitable nature of this attendance under the old system, are

wholly without foundation; for, in the first place, parish authorities were accustomed to take a most dishonourable advantage of medical men, by availing themselves of their readiness to attend sick non-parishioners in cases of emergency, and then protracting or altogether refusing an "order," thus leaving the medical man without any legal claim for his previous exertions and supply of medicines, the charges for which were therefore scarcely ever allowed.

2d. These charges were usually at a much lower rate than ordinary professional demands.

3d. No proof is alleged that these bills, however large in some instances, were not fairly proportioned to the amount of labour and expense bestowed by the attendant, and for which he had no alternative left but to send in an account. Not only, therefore, are the parish medical men most unjustly charged with the evils arising from the system itself, but certain gentlemen, recently intrusted with power under the Poor Law Amendment Act, constitute themselves judges of the remuneration due to a medical man for his professional exertions

I believe that no other liberal profession can be treated in the same way. The charges of a lawyer, if exorbitant, may be referred to Masters in Chancery, &c., members of their own body, and redress obtained from them; but what attorney or solicitor would bear to have his bills submitted to the taxation of his clients?

4th. The attendance on parishioners residing at a considerable distance from the parish was generally part of the contract; a limit of six, or even of ten miles, was not uncommonly specified as the distance within which the medical officer was to attend, free of extra charge. The losses sustained in this way, and by the before-mentioned conduct of overseers and vestries, were such as to render an alteration as desirable to the medical profession as to the rate-payers.

"Rusticus" further announces his opinion that relieving officers are the most competent persons to give orders for medical relief; as he gives no reason for this unaccountable conclusion, I might be content to let it pass without notice, feeling assured that few of your readers who have paid attention to the subject would agree with him. Let me, however, remark, that so long as the power of giving orders depends on the caprice or convenience of a relieving officer, the poor must suffer a needless hardship. Accident and sudden illness require of course much more immediate attention than applications for weekly pay or provisions. The circumstances are totally dissimilar, and the officer who may be qualified and prepared to bestow sufficiently prompt attention on one set of applications, may be, on various accounts, quite unable, as well as unsuitable, to act as the necessities of the case may require in the other.

But "Rusticus," in the plenitude of his knowledge, coolly asserts, "your correspondent 'Ruricola,' is wrong in saying that in some unions a like power is granted to overseers and guardians;" and supports his criticism by a reference to the proceedings in "our union." Now, although I doubt not that this union affords an ample field for observation, I beg to tell him, that I deduce my statement not only from one union, or from half a dozen, but from an extent of country that would make "our union" look rather insignificant. I therefore repeat my former remark, with the additional information that the mode of granting orders is not the same in all unions, some leaving it entirely to the relieving-officer, some intrusting it freely to the guardians and overseers, and others adopting a medium course.

And now, sir, I come to your correspondent's summing up: "Let me warn you against receiving all the statements of medical men on these points. It is their interest to misrepresent the whole of the Commissioners' arrangements on the head of medical relief." A modest accusation truly! Pray what would be said of any medical man who should descend to the ungentlemanlike course of aspersing the motives of the Poor Law functionaries by such remarks as the following:—"Let me warn you against receiving all the statements of the Poor Law Commissioners in their report on medical relief. It is their interest to misrepresent that matter, for in proportion as they reduce any part of parochial expenditure, so do they secure their continuance in office, and their receipt of 2,000*l.* per annum for a longer period;" or, "Do not listen to the statements of guardians; they are considerable rate-payers. It is their interest to misrepresent an expenditure which so nearly affects their own pockets, their object is only to save themselves, whatever may be the miseries of the poor."

If "Rusticus" has no better argument left than to asperse the motives of his opponents, let him prudently forbear; he is handling a weapon which may be turned with double force against himself.

Such, sir, however, are the arguments of those who attempt to defend the present system of parochial medical relief: un-

able to support their proceedings by a reference to the broad principles of humanity and justice, they satisfy themselves, and hope to succeed with the community, by slandering the laborious and ill-requited body of parochial surgeons — gentlemen whose disinterestedness, whose gratuitous exertions, and whose devoted attention to the wants of their suffering fellow-creatures, are probably not surpassed by the excellent qualities of the worthy "guardian" himself.

Your early insertion of this letter will be conferring an additional favour on

Your much obliged and very obedient servant,

RURICOLA.

THE OLD AND NEW SYSTEMS OF PARISH ATTENDANCE.

To the Editor of the Medical Gazette.

SIR,

THE Editor of a contemporary periodical has for some time past manifested symptoms of uneasiness on the subject of the present Poor Law medical contract system, apparently undecided as to the course he should pursue; whether to uphold the profession at the expense of the Commissioners, or the Commissioners at the expense of the profession. Probably if he could have divested his mind of all political associations for the time, and given the subject a fair and impartial consideration, his known tact and ingenuity might have led him to the suggestion of some plan whereby the evils of the present wholesale contract system might in some degree be mitigated. He asks, what is the plan which is to be sanctioned as a substitute? what plan can medical men themselves suggest?

Not being vested with senatorial dignity, it is not to be expected that I should be sufficiently versed in the art of legislation to answer satisfactorily the honourable gentleman's query; nor do I think that it admits of a very ready reply. Looking at the differences which present themselves in all the various unions, it is scarcely to be expected that any one general plan can be laid down, which shall be applicable to all cases. Until some such plan can be devised, I would recommend that the Commissioners should, as a general rule, desist from interfering with existing contracts, and leave it entirely in the hands of the local authorities. It is generally admitted that the old contract system was bad, and in many instances injurious and oppressive, but it will not bear a comparison with the present. Economy has been sufficiently observed, and care enough has been taken by overseers for some time past that the *parish doctor* should not be *too well paid*; and from the knowledge I have of parochial contracts, I feel justified in asserting that no injustice would be done to rate payers by their continuance.

Let the rule be, "to continue the contracts as they are found:" exceptions would, of course, arise; as for instance, where the contracting practitioner lives at such a distance from a parish as to render applications to him by the poor difficult; where the rate of remuneration being higher for any particular parish than for those in the neighbourhood, a saving can be effected by fair and open competition; and in many other cases which could quite as well be judged of by the local authorities as by the Commissioners. I do not mean to assert that, by the adoption of this rule, an equal and just rate of remuneration would be established throughout the kingdom; but I apprehend that such a course would carry much less of tyranny, of injustice, and of petty oppression, upon the face of it, than the compulsory one now in use, and might therefore be adopted until the legislature can provide an efficient and permanent remedy for the evils now so loudly and so justly complained of.

Hitherto parochial contracts have generally been undertaken by medical men with reference to their general practice; and even if it were politic, which I must take leave to doubt, few will be found to assert that it is either just or fair that such arrangements should be wantonly and unnecessarily destroyed—that they should be broken up or interfered with, unless the amount of benefit to the public from such interference be at least equal to the amount of injury inflicted upon the profession. It is to be feared that in many instances country practitioners will find that their practices are much cut up, their means curtailed, themselves deprived of comforts which habit and a somewhat advanced age may have rendered almost essential, the hopes and expectations of their families blighted, and every chance of any future provision for them altogether destroyed; not because any good was to result to the community from the means taken to effect this, but simply because the Poor Law Commissioners, in the plenitude of their liberality, had so willed it. To take a parish from a man who may have had the charge of it for more than a quarter of a century, and whose talents are known and appreciated, merely to give it, perhaps, to some youth

whose only known qualification is his pliant submission to the commands of the Central Board, is too obvious an act of injustice both to the poor and to the profession, to need any comment: equally so is it to amass together several thousand human beings, merely because they all happen to exist within a defined space, and insist upon one man taking charge of the whole, whether it may be compatible or not with his other engagements, or whether it be possible or not for him properly to execute the duties imposed upon him: and still more iniquitous is it arbitrarily to fix upon a rate of remuneration admitted on all hands to be totally inadequate, and to compel acquiescence on the part of the profession by a threat, in many instances carried into execution, of introducing some protegé of theirs, whose character and future conduct may, with tolerable accuracy, be predicted by reference to the character in which he appears. The barefaced injustice,—I may say iniquity, of the present system, is such that I am truly astonished that any set of men of gentlemanly feelings and correct principles can have brought themselves to adopt, or even to sanction it. To the profession I would earnestly recommend that they should keep themselves aloof from, and refuse all intercourse with any intruder who may appear amongst them under such auspices. I would also recommend that all cases of insufficient attendance, whether from neglect or otherwise, should be made known, so that the public may not only know, from time to time, what savings have been effected, but also at what expense of life and misery such savings have been purchased.

Your obedient servant,
EDWARD BARBER.

Cambridge, Dec. 23, 1835.

CURE OF WOUNDS WITHOUT INFLAMMATION.

LETTER FROM DR. MACARTNEY.

To the Editor of the Medical Gazette.

SIR,

I BEG to state, through the medium of your journal, that the paper on the cure of wounds without inflammation, extracted from the Memoirs of the Royal Academy of Medicine, is much changed since it passed out of my hands. Any writing must suffer in style and perspicuity from being translated first into French and again into English; but that would be a matter of minor importance. In my paper, however, there are not only typographical errors, but some passages with a contradictory meaning: the paper is throughout abbreviated, and some essential parts omitted altogether; one in particular, where I claimed the priority with respect to the use of what the French call *irrigation*. There were three lithographic figures, explaining the mode of generating and applying steam, of which no notice is taken.

I take it for granted that the publication in your journal is a translation of the paper as it has been printed by the French Academy, and that the mutilations were made in other quarters, partly from persons not understanding the principles announced in the paper.—I am, sir,

Your obedient servant,
JAMES MACARTNEY.

Dublin, Dec. 23, 1835.

SIR GILBERT BLANE'S MEDAL.

(*From a Correspondent.*)

WE announced, now several years ago, that the venerable and distinguished Sir Gilbert Blane had sunk a considerable sum of money for the purpose of awarding a Gold Medal every two years, to two such Medical Officers of the Navy, serving afloat, whose treatment of diseases and accidents on board of men-of-war was most approved of by the principal Medical Officers of the Navy, and the Presidents of the Colleges of Physicians and Surgeons—the selection of the successful competitors being made by the three named functionaries, after a careful examination of the Surgeons' journals.

Since that period, four awards of the medals have taken place, but none were forthcoming, in consequence of the great delay in cutting the die, and which was a source of great anxiety and uneasiness to the founder, during the last two years of his protracted existence. This, however, has been now accomplished by the completion of the die, and the medals are struck off. It is beautifully executed, and bears a most correct likeness of Sir Gilbert Blane on the *obverse*—as, at least, we understand from a friend, who for 36 years was intimately acquainted with him, and who was shewn the medal by the kindness of Sir William Burnett, of the Admiralty, the present Physician-General to the Navy. The *reverse* is a wounded seaman, apparently lifeless, supported in the arms of another. An erect female figure stands by with a *trident* in her hand (Britannia), and behind her feet a *serpent* entwined with an *anchor*. The motto over the reverse is "Mente Manuque." The money and the die are deposited at the Royal College of Surgeons.

Dec. 29, 1835.

CONCOURS AT STRASBURG.

A CONCOURS was recently held for the Chair of Legal Medicine, vacant in the Faculty of Strasburg by the death of M. Foderé. Two candidates presented themselves, and went through the requisite trials in presence of a large number of spectators. But the judges were dissatisfied, and unanimously determined not to make any nomination. There will consequently be a new contest for the appointment.

COETANEOUS PARALYSIS.

NOTE FROM MR. NOBLE.

To the Editor of the Medical Gazette.

SIR,

You will oblige me by noticing, in your next week's journal, a typographical error, in the publication of my remarks on the subject of Taste and Common sensation, which appeared in the Gazette of last Saturday. I am made to speak of *cutaneous* paralysis of two functions in the same structure; when I wrote, as will be seen on reference to the manuscript, "coetaneous paralysis, &c." This error might be of but little importance, did I not refer, in the next sentence, to cases of simultaneous abolition of motion and sensation as exemplifying such coetaneous paralysis; thereby rendering the novel expression "*cutaneous* paralysis," very much an absurdity.—I am, sir,

Your obedient servant,
DANIEL NOBLE.

Manchester, Dec. 29, 1835.

PHRENOLOGICAL SOCIETY—

LETTER FROM DR. MACLEOD.

To the Editor of the Medical Gazette.

SIR,

THE last number of the Lancet contains what professes to be a report of the proceedings of the Phrenological Society, from which it appears that a recent meeting was devoted to the consideration of certain editorial observations published in the London Medical Gazette, some months ago, in reference to a skull supposed to be that of Dean Swift. Seeing that my name was introduced into the report, and mixed up with much impertinence, in such a manner as to convey the impression that this had been done by the author of the paper, I wrote to Mr. Fearnside, the Secretary of the Society, requesting to be informed whether such was actually the case. To this Mr. Fearnside replied, "I have no recollection whatever of your name having been mentioned by Mr. Hawkins while reading his paper, or, in fact, during the conversation that arose upon it."

It would thus appear that the introduction of my name, the citation of passages with inverted commas as my words, and even the conjectural explanation of the author's motive in selecting me as the victim of his criticism, namely, because "Dr. Macleod professed to be a medical man"—all this, I say, appears to be an unauthorized and dishonest interpolation.

Various circumstances have led to a general belief that the accounts of the proceedings of the Phrenological Society, which appear from time to time, are furnished by a common reporter; but whoever the party may be, as at least he "professes" to be a phrenologist, I take leave to remind him that there are faculties called candour and honesty, which, when but moderately developed, deter men from unprovoked aggression, and prevent them from quoting as the words and opinions of any one, expressions and sentiments which the person named has never acknowledged, and which, as in the present instance, he may have become first acquainted with, like his assailant, from seeing them in the pages of a public journal. It is true, I have not thought it necessary to take notice of the numberless instances in which language and sentiments which were never mine have been attributed to me by the Lancet, because I know that its abuse is part of a system, that it is "a purposed thing, and grows by plot;" but the present case is somewhat different, and I notice it solely because one who, for aught I know, may be a respectable person, is represented—and it would appear falsely represented—as taking impertinent liberties with my name, and ascribing to me a paper of which *I am neither the author nor editor*.

But I have also another motive in making this declaration—my dislike to appear in borrowed plumes; for the paper thus attributed to me is, in my humble judgment, a very clever one, and demonstrates most convincingly, as it is evidently intended to do, either that the skull in

question was not Dean Swift's, or that the present system of phrenology is little better than an ingenious fiction.

I am, sir,
Your obedient servant,
R. Macleod, M.D.

23, Henrietta Street,

COLLEGE OF SURGEONS.

LIST OF GENTLEMEN WHO RECEIVED DIPLOMAS IN DECEMBER.

George Harrison, Great Marlborough-Street.
Alexander C. Morison, London.
T. W. Atkinson, Broughton House, Cartmell.
John R. Wall, Ross, Herefordshire.
Astley Purton, Alcester, Warwick.
George Vaux. Birmingham.
John Lawrence, Brighton.
Henry Bell, Cockermouth.
William A. Cox, Bath.
James K. Parkinson, Hoxton Square.
Samuel K. Parson, Campsey Ash, Salop.
Robert G. Higgins, Newport, Salop.
Henry Weekes, Chatham.
Robert T. Maginniss, E. I.
Charles Stokes, London.
Robert Wilson, Milnthorp.
Andrew M. Needham, Wenn.
James Watson, Sheffield.
James Whitehead, Westwood, Oldham.
James Berry, London.
Richard Jones, Suffolk.
Henry Wilkins, Portsmouth.
Gerrard Potter, Adlington, Lancashire.
Edward J. Staples, Bristol.
John W. Potter, Ongar.
Robert Stevenson, R. N.
Ronald Montgomery, Brentford.
Percival Leigh, St. Cross, Hants.
David N. Carr, Alnwick.
James C. A. Staig, A.
Luke D. Fitzgerald, Ballinarobe, Mayo.
Arthur Stillwell, Uxbridge.
John Bowes, Richmond, Yorkshire.
Thomas Lowe, Solihull, Warwickshire.
Thomas F. Sagar, Leeds.
Anthony C. Clifton, Islington.
Robert V. Leese, South-Street, Finsbury.
William Clark, Devizes.
Thomas Baskerville. Canterbury.
Frederick Cripps, Wisbeach.
Joseph Ward, Birmingham.
George J. Jones, London.
Charles Cooper, Killala, Mayo.
John W. Pearce, Cambridge.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

December 23, 1835.

Geo. Warren Watts Firth, near Norwich.
John Barrett, Corton, Somersetshire.
Edward Hugh Thorpe, Hastings, Sussex.
Charles Bodenham Garrett, Bushey, Herts.
James Compigne Chase, Northampton.
Peter Gregson Heatley, London.
Alfred Heale.
James Buckland, Malmsbury.
Edwin Clarke, Birmingham.
Cardinal Brewster, Tolleshunt D'Arcy.
Richard Nickols, Cawthorne, Yorkshire.

December 31.

William Brook Addison.

LITERARY INTELLIGENCE.

Shortly will be published, a Treatise on the Analysis of Blood and Urine, in Health and Disease; with Directions for the Analysis of Urinary Calculi; by G. O. Rees.

LECTURES
ON
MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XV.

THE MEDICINAL LEECH—ITS PROPERTIES AND USES.

IN my last lecture, I gave an outline of the structure of leeches, and pointed out the zoological characters of those used in this country. It is my intention now to notice the different modes of application; the manner in which these animals perforate the skin; their effects; and uses.

As most persons have had more or less experience in applying leeches, I do not think it necessary to dilate much on this subject. *First*, let the part be well cleansed (sometimes it may be necessary to shave it): then dry the leeches, by rolling them in a clean linen cloth: place them in the lid of a pill-box, and apply to the affected part. This, in my opinion, is preferable to applying them by the fingers, or in a wine glass. A narrow tube (called a leech-glass) will be found useful when we wish to affix one of these animals to the inside of the mouth, or any particular spot.

It is necessary to beware of several circumstances which influence the fixing of leeches. The *first* is the condition of the animal, whether healthy or otherwise. *Secondly*, the nature and condition of the part to which it is applied; thus, leeches will not readily attach themselves to the soles of the feet, or the palms of the hands, or to hairy parts—the presence of grease, vinegar, salt, and some other substances, will prevent their biting; whereas milk, sugared-water, and blood, are said to have the contrary effect. Scarifying the part has been advised to promote their attachment. *Thirdly*, the condition of the patient will affect the fixing of the animal. Derheims says that leeches will not bite those under the influence of sulphur, on account of the evolution of sulphuretted hydrogen by the skin. *Fourthly*, the effluvia, or vapours of the room, as the fumes of tobacco, sulphur, vinegar, &c., it is said by the same authority, will prevent them biting, or even cause them suddenly to fall off.

The quantity of blood a leech is capable of drawing varies considerably. I believe four drachms to be the maximum. In one instance within my own knowledge, this was found to be the quantity, by weighing the leech before and after the operation. This, however, is a rare case. On an average I do not think we ought to estimate it at more than one drachm and a half. Of course this has no reference to that lost after the animal has fallen off, and which varies according to the vascularity of the part, in children being oftentimes very considerable. When the leech has had sufficient it drops off; but it is said that if the tail be snipped, the animal will continue to bite, the blood passing out posteriorly as fast as it is taken in by the mouth. I have tried several, but I find they usually let go their hold the instant the tail is cut. Cloquet has made the same remark.

In order to disgorge the leech of the blood, the usual practice is to apply salt to its body; but it is objectionable, (if you wish to preserve the animal) since the surface is frequently thereby blistered, and several days elapse ere the creature regains its former activity. Some advise squeezing the blood out by the mouth; others the application of vinegar to the head. If no kind of emetic be employed, the blood remains for a considerable time in the stomach of the leech undigested, but without putrifying.

After-treatment. — When leeches have fallen off it is generally desirable to promote the sanguineous discharge, which is best done by the use of warm fomentations or cataplasms; or even, in some cases, by cupping-glasses. When applied to children, be cautious as to the directions you give respecting the promotion of bleeding: your instructions may be misinterpreted either through ignorance or wickedness. Some years since, the application of a leech was ordered to the chest of a child labouring under pneumonia; it was at the same time mentioned that the bleeding should be encouraged. The directions were literally fulfilled—the discharge of blood assiduously promoted—until so large a quantity had been lost, that death was the result. No attempt was made to stop it, nor notice sent to the Dispensary, in the practice of which the case occurred. The child being illegitimate, and the mother evidently careless of its recovery, led some to suspect that this did not take place through mere ignorance. In another instance, two leeches were ordered for a child aged about eighteen months, suffering with pneumonic inflammation, a consequence of measles. The following day the poor little creature was found in a fainting, or rather dying state, with face and lips completely blanched. On inquiry it appeared the leech-bites were still bleeding, and no attempt had been made to stop the discharge, the mother thinking it would be beneficial, more especially as the pneumonic symptoms had considerably abated. As predicted, the little sufferer died within twenty-four hours.

In some persons there appears to be an hereditary predisposition to hæmorrhage, so that very slight wounds are attended with serious, and even fatal effects. Mr. Wilson has related the case of a child where one leech had nearly caused death, by the serious hæmorrhage. When about three or four years old, this child bit its tongue, and notwithstanding that every attempt was made to stop the discharge, death took place from loss of blood.

I have been called to many cases of hæmorrhage after leech-bites, and never failed in stopping it by compression. Sometimes mere exposure to the air will be sufficient; or, if this fail, we may apply a dossil of lint and a bandage. In other instances you will not find this succeed, and there are various plans, any of which you may then adopt. I usually employ compression, thus: roll a piece of lint into a fine cone, and introduce it into the bites by means of a needle or probe; over this lay a compress and bandage. Sponge may be substituted for the lint. Various other modes have been proposed; some, I think, exceedingly cruel, since I do not believe them ever necessary. I allude, now, to the application of a red-hot needle; and to passing a needle through the orifice, and wrapping thread round, just as a farrier stops the discharge of blood from the vein of a horse. Some employ absorbing powders, as gum-arabic; or styptic washes, as a saturated solution of alum. One very effectual means is to apply lunar caustic, or the nitrate of quicksilver. Sir C. Bell, in one case, stitched up the wound.

Leeches in the mucous cavities.—The ancients were very apprehensive of the ill consequences likely to arise from swallowing leeches. That their fears were not groundless, is proved from the following circumstance, related by the celebrated Baron Larrey. When the French army entered upon the deserts which separate Egypt from Syria, the soldiers, pressed by thirst, threw themselves on their faces, and drank greedily of the muddy water, and which, unknown to them, contained leeches (*Sanguisuga ægyptiaca*), having the form of a horse-hair, and the length of a few lines only. Many of them felt immediately stings, or prickling pains, in the posterior fauces, followed by frequent cough, glairy spots, lightly tinged with blood, and a disposition to vomit, with a difficulty of swallowing, laborious respiration, and sharp pains in the chest, loss of appetite and rest, attended with great uneasiness and agitation. On pressing down the tongue of the individual first attacked, a leech was discovered, which was with difficulty removed by the forceps. Little or no hæmorrhage followed, and the patient recovered. Those which had attached themselves to the posterior fauces were removed by the use of gargles composed of vinegar and salt water. The Chief of Brigade, Latour Mauberg, commander of the 22d regiment of Chasseurs, swallowed two in the deserts of St. Makaire, a day's journey from the Pyramids, which so much weakened him, that his convalescence was long and difficult.

Derheims relates a case where a young man, who had leeches applied to his anus, was so unfortunate as to have one enter his rectum unnoticed. The animal made several punctures; and was not expelled until some hours after, when salt water injections were used. The wounds caused by the bites, however, did not heal for several months, during which time the patient suffered considerably, and constantly passed blood with the fæces.

Whenever practicable, salt-water injections should be resorted to. Here, however, is a case in which they could not be employed—it is taken from Derheims. Two small leeches were applied to the gums of an infant during the period of dentition, and by the inattention of the nurse they

fixed themselves at the back part of the mouth, and becoming gorged with blood, caused great difficulty of respiration. The infant, by strongly closing the jaws, prevented the removal of the animals, who only ceased their hold when they were filled with blood. The hæmorrhage continued for two hours.

In Dr. Johnson's work on the leech, allusion is made to some experiments by Dr. Stevens, from which it would seem that the leech is acted upon by the gastric juice. Now this, as the author remarks, is contrary to what one would suppose. That these animals may, when taken into the stomach, occasion serious symptoms, and, therefore, are not immediately digested, is proved from the following case taken from the "*Recueil Périodique.*" A lady accidentally swallowed a leech she was applying to her gums. Acute cardialgia soon came on, with a feeling of erosion, and creeping in the interior of the stomach; sometimes convulsive movements in the limbs and muscles of the face; frequency and irregularity of the pulse; universal agitation and paleness of the countenance. The physician who was called in, recollecting the fact ascertained by Bibiéna, that leeches could not live in wine, administered half a glass every quarter of an hour. The symptoms were soon alleviated; and the fourth dose caused vomiting, by which the dead leech was evacuated, with much glairy matter, mixed with clots of black blood. By a proper subsequent treatment the patient recovered in eight days.

Manner of biting.— Let us proceed to examine the mode by which a leech perforates the skin and extracts blood. When about to bite, you observe he first attaches himself by his posterior disk, feeling about with his head until he finds a fit spot to attack. Here I may remark, that, by some writers, the two terminal disks have been compared to cupping-glasses or suckers in their action; and their adhesion to solid bodies, therefore, referred to atmospheric pressure; but in consulting the works of some of our best writers on this subject (Thomas, Carena, de Blainville, and Brandt), you will find this mode of operation denied. If it be true, (and Blainville says it is), that leeches can affix themselves to solid bodies, and draw blood as well in the vacuum of an air-pump as in the open air, it must be admitted the hypothesis of the cupping-glass operation is no longer tenable. But other reasons have also been urged. It is said, that when a leech has attached itself to a glass, you may slide it along even with part of the disk separated, without the animal letting go its hold; and that when deprived both of head and feet, it can fix itself to bodies merely by pressing its belly against them. It appears, then, that adhesion is effected by the immediate contact of all the points of the expanded disk. Such is de Blainville's explanation (and the other authorities quoted coincide with him); but he admits that the attachment of the anterior disk may at first be effected by atmospheric pressure; adding, it is certain that when this adhesion is complete, it is equally made by the immediate contact of the widened lips. But to return to the mode by which the animal perforates the skin.

Having fixed on a spot suitable for his operations, he applies his oval disk, and firmly fixes it (at first, perhaps, by atmospheric pressure; then by intimate contact), so that the anterior end forms an angle with the other portions of the body. The three cartilaginous jaws bearing the sharp teeth, are now stiffened and protruded through the tri-radiate mouth against the skin, which they perforate, not at once, but gradually, by a saw-like motion. Dr. Johnson says, the jaws are carried from side to side in an oblique direction; and adds, "their action may be seen by presenting to the leech a coagulum of blood, and when the leech is in the act of suction, cautiously removing it. For a few seconds it appears unconscious of its removal, which presents a fair opportunity of observing the oscillatory movement of each piercer" (jaw). He likewise infers that the wound is not produced instantaneously, from the circumstance of the gnawing pain continuing for two or three minutes after the animal has commenced operations. Thus, then, it appears that the leech rather tears than cuts the skin: hence the irritation and inflammation frequently produced around the orifices. The flow of blood is promoted by the suction of the animal, who swallows the fluid as fast as it is evolved. During the whole of the operation the jaws remain lodged in the skin. In proportion as the anterior cells of the stomach become filled, the blood passes into the posterior ones; and when the whole of this viscus is distended, the animal falls off. On examination it will be found that not a particle of blood has passed into the intestine.

Effects.—There are two classes of phenomena observed in all modes of drawing blood; one of which has been termed *local*, the other *general*. In phlebotomy and arteriotomy, the first is trifling, and of no therapeutic value; and we resort to these operations only as means of affecting the general system. On the other hand, we obtain topical effects, both powerful and useful, from cupping and leeching; hence these are termed *local*, while the former

are denominated *general* blood-lettings. It must, however, be remembered, that constitutional or general effects are also frequently obtained from both cupping and leeching.

1. *Constitutional or general effects of leeching* are the same in kind as those caused by the loss of blood from other means. A moderate quantity may be abstracted without any obvious effects on any of the functions; but if the amount taken be increased, the well-known "syncope" is the result. The quantity necessary to produce this varies, however, considerably, and will depend on the mode of drawing it, (whether rapidly, or otherwise); the position, constitution, and age of the patient; the nature of the disease; and many other circumstances, not necessary for me to enumerate. It is well known, that a small quantity will, if taken rapidly, and the patient be in the erect posture, cause this effect; whereas a considerably larger amount may be abstracted, if taken gradually, and the patient in the recumbent position, without giving rise to it. The usual explanation of this is, that when the blood is drawn faster than the vessels can contract, the circulation is temporarily stopped, and fainting ensues. Several reasons, however, lead me to doubt the sufficiency of this explanation. Leeching, then, as being a slower mode of abstracting blood, is less likely to cause syncope than venesection, or even cupping.

But there is another immediate effect of loss of blood, which may either accompany syncope, or occur independently of it;—I mean disorder of the cerebral functions, as marked by convulsions, delirium, or coma. On this subject you will find some interesting remarks in the work of my able colleague, Dr. Marshall Hall, on the "Morbid and Curative Effects of Loss of Blood." I may observe, that convulsive movements are by no means uncommon in syncope from general blood-letting, and I think are not always to be considered as denoting that the remedy has been used beyond the safe degree. I have on several occasions been told by patients about to lose blood that they are apt to faint and struggle when bled, and I have in consequence been requested to prevent them from injuring themselves. Delirium and coma are less frequently met with. In two or three instances I have seen delirium occur after blood-letting, but have not been satisfied whether it was the effect of the disease or of the remedy: coma I have never seen result from bleeding. Both symptoms must be regarded as serious and dangerous when they do occur. There is, lastly, another effect of loss of blood, namely, great depression of the vascular system, followed by sudden dissolution. A case of this kind is mentioned in the 11th volume of the Lancet, page 94, as having occurred in St. Bartholomew's Hospital.

It is necessary that I should notice some other consequences of blood-letting;—I mean the immediate effects this agent has over the disease, and which, in contradistinction to those before mentioned, we may denominate therapeutic. As might be expected, an operation so powerfully affecting the vital functions cannot be passive in its influence over morbid action, but the phenomena vary so much in different diseases, and even in the same disease under different circumstances, that it becomes extremely difficult to offer any general results. That loss of blood is sometimes beneficial, at other times hurtful, is well known. Of its immediate beneficial effects, I may offer one or two illustrations. In inflammation of the lungs, I have repeatedly heard patients declare that the respiration became easier, and the pain removed, while the blood was flowing; and in some cases from this time amendment took place. In ophthalmia, the redness of the conjunctiva disappears during the syncope from blood-letting, and sometimes never returns with equal intensity.

Having now noticed the most important effects of blood-letting, I may here remark, that they are considerably influenced by disease. You will recollect in a previous lecture I alluded to the Italian doctrine of contra-stimulus, and mentioned it was supposed by the followers of this theory, that, during a state of excitement, the system was capable of bearing or tolerating a much larger dose of certain medicines termed contra-stimulants, than could be endured in the natural or healthy condition. Now precisely the same kind of doctrine is held by Dr. Hall with respect to the relative effects of blood-letting in health and disease. Every practitioner is acquainted with the fact, that, in certain morbid conditions, patients bear the loss of larger quantities of blood than in others. I need only mention apoplexy, inflammation of the serous membranes, peripneumony, and phrenitis, as examples of increased tolerance; while chlorosis and cholera may be cited as instances of diminished tolerance. On this point there cannot be, I think, two opinions.

I confess I am not prepared to assent to the inferences Dr. Hall has drawn from these facts, nor to the rules he has laid down in the diagnosis and treatment of disease founded on the circumstances just mentioned. The susceptibility to syncope is so great in some persons, that we should, I suspect, be often led into error, if we

were to infer the absence of inflammation merely from the occurrence of fainting after the loss of a few ounces of blood. Besides, it not unfrequently happens that a patient faints on the first, but not on the second or third bleeding. I have more than once seen this; and my friend Dr. Clutterbuck, whose extensive experience in the use of this remedy is well known, and who I am happy to find is about to give the profession the results of his practice, assures me he has frequently observed it. Neither do I think it would always be safe to bleed *ad deliquium*, even if we are satisfied that inflammation be present; for in some it is difficult to occasion syncope, although the quantity of blood lost be so great as to endanger the safety of the patient. The practice of Dr. Hall, however, is much to be preferred in this respect to that of Mr. Wardrop; for although both recommend bleeding to syncope in inflammation, the former places his patient in the erect, the latter in the recumbent posture. And here I cannot help remarking that the practice of ordering patients to be bled to syncope in the recumbent posture appears to me a dangerous one. That fainting will sometimes occur in the erect position, before a sufficient quantity of blood has been drawn, we all know; and to prevent this occurrence, it is frequently proper to bleed in the recumbent posture: but I must protest against bleeding patients to *syncope* in this position.

I have yet to notice another class of the general effects of loss of blood, which may be denominated secondary or remote, and which are in no way useful in the treatment of disease. In some cases excessive reaction occurs, attended with throbbing of the vessels of the brain, pain and disorder of the cerebral functions. You will see examples of this in women who have suffered severely from uterine hæmorrhage. The two children killed by leeching, already alluded to, were examples of death caused by exhaustion from loss of blood with insufficient reaction. Other secondary or remote effects of blood-letting are mentioned: they consist principally in disorder of the sensorial functions, marked by delirium, coma, or even amaurosis. For cases I must refer to the works of Drs. Abercrombie and Hall, and Mr. Travers.

Having hitherto spoken of the consequences of bleeding generally, I must now refer more particularly to leeching. The constitutional or general effects caused by the application of leeches are best observed in children and delicate females—more especially the former. I have, on several occasions, seen infants completely blanched by the application of one or two leeches Pelletan mentions the case of a child, six years old, who died from the hæmorrhage occasioned by six leeches applied to the chest. Leeching, then, is here, to all intents and purposes, a mode of general blood-letting, arising in part from the powerful influence which a small quantity of blood produces in infants; and secondly, because one leech will cause the loss of more blood in them than in adults, owing to the greater vascularity of the cutaneous system. It is apparent, therefore, that in the diseases of children leeching may, in most cases, be substituted for venesection. But in disorders which are rapidly fatal, as croup, opening the jugular vein is undoubtedly to be preferred, since it is necessary to produce an immediate and powerful effect. As children advance in years they become capable of bearing larger evacuations of blood; and, therefore, leeching excites a less influential effect. It is quite impossible to say at what age venesection ought to be substituted, or, in infancy, what number of leeches should be applied; since they take away such unequal quantities of blood. These are points that must be decided by the practitioner in each case. Here is a tabular statement of the amount of blood which Dr. James Blundell has taken from children at different ages.

Ages.	Quantities
2 months	1 oz. to $1\frac{1}{3}$ oz.
4 months	$1\frac{1}{2}$ oz. to 2 oz.
8 months	2 oz. to 3 oz.
12 months	3 oz. to 4 oz.
18 months	4 oz. to 5 oz.
3 years	8 oz. to 10 oz.
6 years	10 oz. to 12 oz.

But the quantities are exceedingly large, and in most instances greater than you will find it prudent to abstract. Guersent, physician to the Hôpital des Enfans, at Paris, says, that in infants up to two years of age, we ought never to draw more than three or four ounces of blood in twenty-four hours.

2. *The local effects of leeching* must now be noticed. The jaws of the leech may be compared to three saws, each armed with sixty teeth. You will, therefore, not be surprised at the pain and afflux of blood occasioned by the laceration of the skin by a single leech. I have sometimes seen one of these animals produce intense redness to the extent of an inch around the bite. You will best observe this when the skin is delicate, as that covering the mammæ of the female. When a number of these animals are applied, their united local effects must have some influence over a neighbouring disease.

There are also certain topical effects which occur subsequently—such as ecchymosis,—the irritation and inflammation of the lips of the punctures,—the diffused redness and the soreness in the parts intervening between the bites; which cannot be without influence over morbid action. They act on the principle of counter-irritation. In taking into consideration the beneficial influence of leeches, we must, therefore, not forget these, nor the fomentations and poultices subsequently employed.

When leeches are applied to the temples, especially if they fix close to the external canthus, a diffused swelling frequently arises, similar to that caused by erysipelas. This is not referrible to any noxious qualities of the animal, for it happens when the finest and most healthy are employed; nor to the teeth of the animal being left within the wound, since I have frequently seen it when the leech has fallen off spontaneously.

In concluding these remarks on the local effects of leeches, I have only to add, that independently of the local irritation caused by the puncture, I believe the evacuation of blood from an inflamed part may be more beneficial than the same quantity taken by the usual operation of venesection. In other words, I am disposed to admit what were formerly termed the *derivative* effects of local bleeding. The amount of benefit obtained by the application of leeches to parts that have been injured by falls, &c. as in fractures and dislocations, has frequently appeared to me much greater than could be referrred to the combined influence of the quantum of blood lost, and the local irritation of the punctures; so, also, with respect to the good effects of leeching hæmorrhoidal tumors. Mr. Wardrop thinks, more benefit is in some cases obtained by the application of leeches at a distance from the affected organ, constituting what has been termed a *revulsive* operation.

I trust the remarks now offered will be sufficient to prove, that in estimating the therapeutic influence of leeches, the quantity of blood drawn is not the only element in the calculation; and I think, in practice, you will find constant proof that leeching is more beneficial than can be accounted for by the mere quantity of blood drawn.

On the *uses* of leeches I must necessarily be very brief, since to enter properly into the subject would involve pathological details unsuited to pharmacological lectures.

1. In children and delicate adults, as females and aged persons, leeches will be found an exceedingly useful substitute for general blood-letting, where the object is not to occasion any immediate or sudden effect on the disease. In children, avoid applying them to the neck, or other parts where compression cannot be conveniently made.

2. In local determinations of blood, unattended with febrile symptoms, local blood-letting, when it can be resorted to, is generally, though not invariably, preferable to phlebotomy. The advantages of leeching over cupping are, the less pain, and the ease with which blood may be procured; for it is evident that in swelled testicle, in inflammation attending fractured limbs, and in acute inflammation of the mammary gland, patients could not, in most cases, bear the necessary pressure of the cupping glass; and in some parts of the body, as the abdomen, blood can only be procured from cupping by a very dexterous manipulation.

3. In internal and other inflammatory affections, accompanied with constitutional disorder, the rule is to employ general in preference to local blood-letting. But circumstances occasionally render the reverse practice justifiable and proper, as where the disease is not active, and the patient delicate and weak. In many instances you will find it most advantageous to combine both modes of drawing blood: for example, in abdominal inflammations, the application of leeches, preceded by venesection, will sometimes do more good than the same quantity taken by the lancet alone.

4. There are some diseases in which no substitute of equal efficacy can be found for leeches. Such, I conceive, are hæmorroidal tumors, and prolapsus of the rectum. In these cases general is not equal to local blood-letting, and cupping is out of the question.

5. In various organic diseases leeches will often be found an exceedingly useful palliative means. I would particularly mention as examples, affections of the heart and lungs.

There are few diseases in which loss of blood is required, where leeching is positively objectionable; indeed, erysipelas is almost the only one that can be named. Here it has been supposed that the local irritation caused by leeches would add to the severity of the malady; but I believe that even in this case, the objections are more imaginary than real. There are, however, numerous instances in which leeching is negatively objectionable: in some the quantity of blood drawn by these animals is insufficient to make much impression on the disease, as in visceral inflammation of robust persons; in others, where the disease is very rapid and fatal, the effects of leeches are too slow, as in

croup. Venesection is the remedy in all these instances. Bear in mind, however, that the weakening effect is always proportionate to the quantity of blood drawn.

I proceed to examine those animals used in medicine which belong to the

CLASS INSECTA.

The bodies of insects are frequently marked by deep insections, from which the class has received its name; but you will bear in mind that the other divisions of articulata also possess this character.

Definition.—Insects are articulated animals, having three pairs of articulated members, breathing by tracheæ, provided with antennæ, and passing through several transformations and changes, denominated their metamorphoses. Essentially these animals are oviparous, but in some instances the egg is retained in the body of the mother until it is hatched (constituting the animals formerly termed *Insecta ovo-vivipara*), or until it is transformed into the pupa state.

Metamorphoses.—In insects there are four distinct stages of existence, namely, the egg, the larva, the pupa, and the imago.

1. The *egg*, or *ovum*, varies in its shape.

2. The *larva* is the young insect produced by the egg. In those insects which undergo what are called *imperfect metamorphoses*, the larva has the form of the parent, but is destitute of wings. In most cases, however, the larva (although containing within it the rudiments of the future insect) has an exterior form very different from that of its parent: these are the animals that undergo the *complete metamorphoses*. The larvæ of the latter possess the same general structure as the Annelides; sometimes having neither distinct head nor feet, when they are called *maggots*; sometimes possessing a distinct head and six feet, constituting the *larvæ* commonly so termed; and in other cases, besides six horny, there are several membranous legs; these are termed *caterpillars*, or *erucæ*.

3. The *pupa*, or third stage of development, is formed by the larva throwing off a number of membranous coverings. In this state the insect takes no food, and, generally, does not move. In those with incomplete metamorphoses, the pupæ are furnished with the rudiments of wings, and are called *nymphæ*. Those pupæ which have a gold colour are denominated *chrysalides*; though this term is by some applied to all pupæ, by others to the pupæ of butterflies.

4. The *imago*, or *perfect insect*, is the term applied to the animal when it quits its pupa case.

The nomenclature of the parts of the perfect insect will require a short notice. In all perfect insects we distinguish three divisions of the body of the animal, namely, the head, the thorax, and the abdomen.

1. The *head* (*caput*) has attached to it the parts of the mouth (*partes oris*), the antennæ, and the eyes. The mouth consists of an upper lip (*labrum*): a lower lip (*labium*), with its palpi (*palpi labiales*); a pair of upper jaws or mandibles (*mandibulæ*), without palpi; a pair of under jaws (*maxillæ*) provided with palpi (*palpi maxillares*). The *antennæ* are two articulated bodies, one of which is placed on each side of the head, between the angles of the mouth and the eyes. The eyes (*oculi*) are of two kinds, those called compound (*oculi compositi*) and those denominated simple (*oculi simplices, ocelli, stemmata*).

2. The *thorax* consists of three segments (each perforated by the air-hole, called *stigma* or *spiracula*), the anterior called *prothorax*, the middle termed *mesothorax*, the posterior denominated *metathorax*. The prothorax supports the first pair of legs; the mesothorax supports the second pair of legs and the first pair of wings; while the metathorax sustains the third pair of legs and the second pair of wings. The part of the legs are named after those of vertebrate animals, and thus we have the following joints or pieces,—the *coxa*, the *trochanter*, the *femur*, the *tibia*, and the *tarsus* (the latter made up of from one to five joints). The first or anterior pair of wings, when horny, have been termed wing-cases, or *elytra*.

3. The *abdomen* is made up of a varying number of segments, each perforated by the air-hole (*stigma* seu *spiracula*).

Orders of insecta.—Latreille, in Cuvier's Règne Animale, admits twelve orders of insects. One of these,—the myriapods, is, by almost universal consent, now made a distinct class, since the animals of this division differ from those properly called insects both by their external and internal structure. Three orders are described by him as being wingless (*aptera*), namely, *thysanoura, parasita*, and *suctoria*. But as almost all the orders contain apterous insects, it would be evidently better to take our divisions from some other character than the presence, absence, or number of the wings. Now, it is generally admitted that we derive much more constant characters from the metamorphoses and the structure of the mouths. Dr. Hermann Burmeister has, on these principles, founded a classification which appears to be much more correct. Here is a sketch of his arrangement; and for further details I must refer you to his valuable work, "*A Manual of Entomology*," now being translated by Mr. Shuckard.

		Orders.	*Examples.*
Metamorphosis imperfect.	Mouth suctorial	1. Hemiptera	Bugs, Cochineal, &c.
	Mouth masticating	2. Orthoptera	Locusts, Grasshoppers, &c.
		3. Dictyoptera	Cockroaches.
Metamorphosis perfect.	Mouth suctorial	4. Diptera	Flies.
		5. Lepidoptera	Butterflies, Moths.
	Mouth masticating	6. Neuroptera	Dragonflies.
		7. Hymenoptera	Bees, Wasps, &c.
		8. Coleoptera	Cantharides, &c.

On this arrangement I have to remark, that by an imperfect metamorphosis is meant, the strong resemblance of the larva, pupa, and imago, to each other, the pupa possessing locomotion, and eating; whereas in those insects with a perfect metamorphosis the larva is a long maggot or caterpillar, or wornil, the pupa being generally quiescent, and not eating.

In my next lecture I purpose examining the coleopterous insects employed in medicine.

LECTURES

ON

SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

ON SYMPTOMS.

Subject continued—Mixed Phthisis—The mixed character of its Auscultatory Signs.

I HAVE described two forms of Pulmonary Consumption, distinct from each other in certain pathological particulars, and distinct also in their Auscultatory Signs. Both were specimens of genuine and unmixed Phthisis;—genuine, because they consisted of tubercles and vomicæ, which are the essence of the disease; unmixed, because they consisted of tubercles and vomicæ *only* from first to last; these fulfilling their specific morbid processes within their specific limits, and leaving all other parts of the lungs which they do not actually occupy free from disease.

These two forms of Phthisis were represented as chronic; and chronic they are generally found to be: for disease which does not easily impart irritation to surrounding structures, is usually slow in its own actions.

Observe, I am not making distinctions of Phthisical disease for purposes of mere arrangement and nosology; but I am selecting such forms of it as I find suitable to the purpose I have in hand; that purpose being to show that there is such a disease as genuine and unmixed Phthisis, discoverable by Auscultation, and distinguishable by Auscultation from *mixed* Phthisis, which is presently to be considered.

There are forms, then, of Pulmonary Consumption, which Auscultation is able to distinguish from those already described mainly in this particular circumstance, viz. that the tubercles and vomicæ produce and spread abroad other disease within the lungs beyond the parts which they themselves occupy, and beyond the sphere of their own specific actions; and that other disease is Inflammation. These forms are characterized during life by a mixture of the Auscultatory Sounds belonging to Phthisis, and the Auscultatory Sounds belonging to that other disease; by those which denote tubercles and cavities, and those which denote effusion, of whatever kind, into the bronchial and vesicular structure of the lungs; by dulness beneath the clavicles or about the scapulæ, or by Cavernous Breathing or Bronchophony, Gurgling Breathing, Gurgling Cough or Pectoriloquy; and, at any or every part, where these are not found, by Sibilus or large or small Crepitation.

The Phthisical disease, however, must have reached a certain point of its development, before each order of Auscultatory Sounds is clearly discernible.

Hence there are cases in which the disease indeed is mixed, or of two kinds concurrently, while the Auscultatory Sounds are of one kind only. The specific Phthisical disease and the common Inflammatory disease exist together; but at the same time the Auscultatory Sounds present only indicate the one and not the other: and, strange to say, the sounds that *are* present often belong, not to the *primary* Phthisical disease, but to the Inflammation which is secondary and incidental to it.

Mere tubercles, at their first formation, are capable of imparting such irritation to the whole lung, as to produce inflammation of its entire bronchial and vesicular structure, and an early and an abiding effusion within it; and this effusion gives occasion to its own Auscultatory Signs. But the tubercles themselves may be so scattered through the lungs, and so little

accumulated in any one situation, as of themselves to cause no perceptible obstruction to the passage of air, and consequently to give no Auscultatory Signs by which they could be suspected to exist, even if there were no disease beside themselves.

In the autumn of last year (1833) a young man (Thomas King) was admitted into this hospital, and remained here three months, until he died. His case is so important pathologically, and so aptly illustrative of those practical points I am now considering, that I must be allowed to dwell upon it a little at large.

He had already been ill three months before his admission. His complaint began with Hæmoptysis, which occurred to the amount of four or five ounces when he was making some unusual exertion, and continued in smaller quantities for a few days, and then ceased altogether.

At his admission he was pale and emaciated; his pulse was 140 in a minute, and of extreme feebleness. He had profuse perspirations at night; he suffered an agonizing Dyspnœa, and brought up a scanty glutinous expectoration, with great effort of coughing.

Auscultation discovered at this time a clear respiratory murmur in every part of the left lung, and in the right a clear respiratory murmur, confined to its *very upper* part, and then a widely-diffused small Crepitation, which gradually faded away into absolute dulness as you approached nearer the bottom. It was not long, however, before the condition of the left lung was the same to Auscultation as the right.

I know no distress greater than that which attends the collection of viscid mucus in the lesser bronchi and vesicular structure of the lungs. There is a constant dyspnœa and ceaseless provocation to cough, and an agony, and striving to tear up from the respiratory passages something that will not come. Such distress was unmitigated in this poor fellow for three months together.

This same condition of the lesser bronchi and vesicular structure, when it results from acute inflammation, seldom lasts long; yet even for a few days the agony of the Dyspnœa and fatigue of the Cough are hardly tolerable. But *here* they were abiding and unaltered for three months, kept up by inflammation (if you please), but inflammation of no action and no power, where the pulse was always of extreme frequency and extreme feebleness.

No remedies that were employed at all assuaged the distress or altered the conditions of disease within the chest; and the Auscultatory Sign to the last, the only sign, was small Crepitation largely diffused through both lungs, which, at their lower part, were almost dull. He died exhausted.

Now, long before his death, I certainly did suspect that this effusion throughout all the Bronchial passages was not kept up solely by the idiopathic disorder of their lining membrane, but that something would be found elsewhere within the lungs capable of producing and maintaining it; and I certainly did conjecture that we should find tubercles, partly from the whole malady having commenced with Hæmoptysis, and partly from not knowing what else there could be.

Dissection discovered the pleura adherent on both sides,—on the left partially, on the right universally; and the whole membrane converted into a thick cartilaginous substance; the entire lungs loaded with bloody serum, and their whole texture so softened as to break down easily under pressure of the fingers. These were all the results of common inflammation, which had reached to every tissue which composes the structure of the lungs.

But dissection discovered, moreover, myriads of tubercles, distinct, and sprinkled universally throughout the lungs; grey, and as minute as millet-seeds, in the lower lobes, yellow and of a larger size in the upper.

This is not a common specimen of disease, but it is a very instructive one, and *therefore* I have quoted it. It is remarkable, in contrast with the forms of Pulmonary Consumption which I have before described, that *here* the minutest tubercles, not one of which had passed on to the state of vomica, should be capable of producing inflammation, and diffusing it so generally, and maintaining it so constantly; and that these mere tubercles could continually supply such an amount of irritation that no remedy should in the least degree abate the inflammation (otherwise perhaps curable in itself) which they were always present and ready to renew. In this case the secondary and incidental morbid processes entirely outran those which were primary and specific; and the patient perished of inflammation of the entire lungs, the Phthisical disease having not passed beyond its earliest and tubercular stage.

But, trusting to my own experience, I should say, that it was a rare thing for Pulmonary Consumption thus to kill, by producing *chronic* inflammation and *chronic* effusion into the entire bronchial and vesicular structure of the lungs, itself still remaining in the tubercular stage, and the tubercles not yet occasioning any auscultatory impediment to the passage of air. It is more according to my observation that, *in this stage*, or under these conditions, it should produce *acute* inflammation,

either proving fatal in a few days, or requiring active treatment to prevent it from becoming so. And it is still more according to my observation, that in this stage, or under these conditions, it should produce Hæmoptysis; which also may be called acute, being accompanied by fever and much vascular action, and liable, too, to prove fatal in a few days, or requiring active treatment to prevent it from becoming so. In the fatal cases the unsuspected tubercles are only discovered after death.

Yet attacks of acute Inflammation or acute Hæmoptysis from such a cause are not usually fatal: but, the cause still remaining, they are apt to recur again and again; and at length, when the tubercles increase sufficiently to obstruct the passage of air through certain parts, and to occasion dulness here and there, and a more energetic and compensating respiration elsewhere, then the secret of the former inflammations or hæmorrhages are revealed. At this point the mixed characters of the disease begin to declare themselves by the mixed characters of the Auscultatory Signs.

Now, although Pulmonary Consumption (as we have seen) unquestionably can, and sometimes does, produce Inflammation or Hæmorrhage of the Respiratory Passages, long before it is so far developed as to give any direct tokens of its own existence, yet this is not the usual course: it most frequently happens, that neither Inflammation nor Hæmorrhage are added to it, until tubercles have at least reached that degree of accumulation when they begin to give occasion to certain Auscultatory Signs of their own.

I think I have observed that, as long as the Pulmonary Consumption remains in its tubercular stage, if an Inflammation or a Hæmorrhage be added to it, they are apt to occur in distinct attacks, occasionally and casually.

I formerly mentioned the frequent cases of Hæmoptysis admitted into this hospital, which were connected with tubercles of the lungs. The attack is usually sudden; the quantity of blood lost in a short time considerable; the treatment required usually active; and the result, as far as the mere hæmorrhage is concerned, usually successful. Moreover, the Auscultatory Signs denote the mixed nature of the disease. While the spitting of blood continues, and perhaps for a short time after it has ceased, there is a large or small Crepitation commonly arising from a considerable space at the lower part of one or both lungs. This denotes the bronchial or vesicular effusion, as distinguished from the deposition of tubercles. Then there is a diffused dulness both to Percussion and Auscultation somewhere, perhaps between the clavicle and mamma on one side, and an exaggerated respiratory murmur somewhere else, perhaps between the clavicle and mamma on the other side. These denote the deposition of tubercles, as distinguished from the bronchial or vesicular effusion.

To my experience bronchial or vesicular hæmorrhage is more familiar as an accompaniment of Phthisis, as long as it continues in its tubercular stage, than bronchial or vesicular inflammation; the effusion of blood than the effusion of serum or mucus. But when Inflammation *does* occur, I have generally remarked in it the same circumstances and attendant conditions which belong to the Hæmorrhage, the same sudden and distinct mode of attack, and that degree of excitement of the blood-vessels which requires the same treatment, and the same successful result. Moreover, there have been the same Auscultatory Signs, namely, crepitation at the lower part of the lungs, produced by the effusion of serum or mucus; and dulness at the upper part, produced by the deposition of tubercles. The only difference is, that in one case serum or mucus is expectorated, and in the other blood.

I here speak of Hæmorrhage and of Inflammation as of two things, not wishing to swerve from the customary language of medical men; but, if I might use my own language, I should speak of *vascular action terminating sometimes in effusion of blood*, and *sometimes of serum or mucus*, as of one thing tending to two results; for whether the result be the effusion of blood, or the effusion of serum or mucus, the vascular action requires the same treatment according to its degree, and is as much inflammatory in one case as the other. Moreover, it is this vascular action which is our only practical concern; we treat it, and *it only*, and have no special care of either blood, serum, or mucus, for which in themselves we can do nothing.

But it is when Pulmonary Consumption has advanced beyond the tubercular stage that we find the most frequent examples of its mixed character. Bronchial or vesicular effusion is almost the constant accompaniment of vomicæ; and the expectoration is now often as much supplied by the mucous lining of the air passages as by the cavities themselves.

You have only to go into the wards of the hospital, and you may at once acquaint yourselves in a dozen instances with the mixed character of the auscultatory sounds. Gurgling cough, gurgling and cavernous respiration, pectoriloquy, one, or several, or all together, will shew that this, that, and the other patient, have Vomicæ in their lungs; and large and small Crepitation, one or both concurrently, will shew

also that this, that, and the other patient, have fluid effused here, there, or every where, within the respiratory passages.

Now when vomicæ have been long formed, and the expectoration long established, Hæmorrhage and Inflammation are less liable to occur in sudden and distinct attacks. The blood, or mucus, or serum, which are now separated from the surface of the air passages, result from a vascular action of less force, but of more permanency, and are themselves more abiding.

It should be remarked, however, that blood, which is more common in another stage of Pulmonary Consumption, is more rare in this; not that blood does not *now* sometimes appear, but it appears rather as a part of the expectorated matter, and streaking or staining it, than as pure and sincere blood.

Assuredly, after the expectoration is established, sudden and profuse gushes of blood seldom occur. Probably the expectoration itself is the security against them, the circulation thus obtaining all the relief it stands in need of. Probably, too, the security becomes greater in proportion as the expectoration is more copious and more free, and proceeds from a larger extent of mucous surface.

All this is, in the nature of things, very probable, and it is confirmed to me by the striking fact which, in a few instances, I have known, of a copious muco-purulent expectoration suddenly ceasing, and a frightful Hæmoptysis at once bursting forth; as if the circulation, being suddenly baffled, had sought and found the nearest way to free itself. In these instances, when the hæmorrhage ceased, the expectoration was re-established.

It should be mentioned, that in the destructive processes connected with the formation of many and large Vomicæ, the blood-vessels of the lungs do not always escape ulceration, or rupture, while they are yet pervious; and then a mortal hæmorrhage is the consequence. But such hæmorrhage is purely accidental, and independent of any proper hæmorrhagic action (if I may so call it) in the vessels themselves.

Let me guard you against a vulgar error. Hæmoptysis and rupture of a blood-vessel are, in the popular sense, convertible terms; so much is one conceived to be the natural and necessary consequence of the other. But rupture of a blood-vessel, which has been esteemed the only cause of Hæmoptysis, is unquestionably the rarest cause of all; and this accident, which one might expect to find frequent in Pulmonary Consumption, nature has taken great pains to guard against; for no sooner does the destructive process of forming vomicæ within the lungs begin, than she sedulously betakes herself to closing up the arteries which lead to them by clots of blood: and as to the veins, partly (I believe) by the same process, and by otherwise arresting the circulation through through them, she reduces them to impervious shreds.

Now in all cases of Pulmonary Consumption arrived at the stage of vomicæ, I would recommend a constant regard to the extent of the disease beyond its specific limits. I would recommend that, besides attending to the sounds indicative of cavities, you should take especial note of *Crepitations*, and how they vary in the distance to which they spread themselves from time to time. The Gargouillement, and the Pectoriloquy, and the Vomicæ, from which they arise, are beyond our reach *remedially*; not so the crepitations, and the vascular action which produces them. In my treatment of Pulmonary Consumption, I am accustomed to make these crepitations serve me for practical indications, endeavouring by all means to lessen and circumscribe them, and thus seeking, under the guidance of Auscultation, to bring back the disease as much as possible within its specific limits.

The bronchial and vesicular effusion, which is the concomitant of vomicæ, submits itself to the influence of medicine in various degrees. Very often, when there are gurgling cough and gurgling cavernous respiration and pectoriloquy, at certain points, and, withal, large and small crepitations diffused widely through the lungs, a seasonable remedy will entirely sweep away the latter sounds, and leave the former *alone*. A small cupping, a few leeches, a blister, a liniment, a mustard cataplasm—one or other of these, according to the degree of vascular action, applied at the right time and in the right place, will produce immense relief, in this manner bringing the disease for a while within its specific limits.

It is thus, as perhaps you may have remarked, that almost every phthisical patient brought into the hospital experiences great relief for a short time after his admission. The poor, alas! are not only the chief victims of Phthisis, but they suffer the disease with all its occasional superadded evils, which their exposure, their hardships, and their needful toils, will not allow them to escape. With them, the superadded evils are often beyond all proportion to the disease itself. The tubercles and vomicæ may be few, and the bronchial and vesicular effusion immense; and this superadded effusion may be for the first time submitted to a remedy when they reach the hospital, and then it is often in a great part or altogether swept away. No

wonder that, from the relief which follows, the patients should sometimes believe themselves cured at once and entirely.

But the effusion again and again returns, and requires again and again to be abated.

Thus I have given a sketch only of a vast subject, which is interesting, fearfully interesting, to all mankind. I have not crowded it with a multitude of instances, for I had not room for them; and I was afraid they might obscure the outline, which was all I designed to give.

In tracing this outline my own experience has guided me; and yours will soon enable you to fill it up, and to determine how far it is true and how much it is worth.

There are many strange things respecting Pulmonary Consumption — many striking discrepancies between case and case, and many contrarieties of opinion among the well-informed as to its proper mode of treatment, which, heretofore, the best of us have been unable to reconcile or explain. In one case it is a slow decline; in another a gallopping consumption. It is spoken of as incurable; and yet now and then an individual recovers, or seems to recover. Some are for treating it by bleeding. Some by bark and steel, and ammonia. Some restrict their patients to vegetables and asses' milk, and some give them animal food and wine; and all can boast of their success.

But these things have now ceased to be mysterious any longer; thanks to a more enlightened pathology and to that method of diagnosis which not only marks the due course and progress of the specific disease, but does not allow even emergent and contingent events to escape its scrutiny.

This same method, still aided and guided by a just pathology, has enabled us to discern more clearly the avenues through which nature admits relief, and to direct our remedies with a steadier aim, albeit such remedies are of various and even opposite kinds.

Unquestionably, within the limits of *possible* success, Auscultation has contributed to render our treatment of Phthisis more successful.

It has been the means of discovering no new remedy. How should it? It has made nothing curable now, which was incurable before. But, while it has taught us to distinguish the unmixed from the mixed Phthisis, the disease from its accidents, what is reparable from what is not *in the patient while yet alive*, it has enlarged the resources of practical medicine, by more clearly presenting to it the objects within its reach.

By keeping those objects, thus offered to you, steadily in view, you will be able to fulfil more satisfactorily every purpose that rational treatment can contemplate in a disease which, if it be not incurable, is rarely cured. You will know better how to remove its many superadded evils, to postpone or mitigate its many pains, perhaps to lengthen life, and to procure for it, while it lasts, some share of happiness.

I cannot finish this little sketch of Pulmonary Consumption, and of the uses which Auscultation serves in distinguishing its kinds, and in furnishing guidance for its treatment, without adding one further remark, and it is *this*:—In Pulmonary Consumption death not unfrequently arrives at a much earlier period than seems consistent with the morbid processes going on within the chest. Patients die sometimes long before the disease of the lungs has reached the point at which it is necessarily fatal. I do not mean that phthisical patients may chance to suffer Fever or Cholera, or may chance to break a limb, and so die of other diseases or accidents. These cannot be anticipated or guarded against. But I mean something more worthy of our consideration.

In proportion as we are more intent upon investigating the local processes of diseases in a particular organ, scrutinizing them pathologically, and nicely weighing their Diagnostic Signs, there is a danger that our minds may be withdrawn from those larger views which regard their constitutional origin, and their consequent liability to fall upon any or all organs of the body. Thus, while we are expecting a man to die of Pulmonary Consumption a twelvemonth hence, he may die in the meantime of (if I may so speak) Intestinal Consumption, Peritoneal Consumption, Mesenteric Consumption, or Vertebral Consumption. For, from the same strumous constitution, which engendered tubercles and vomicæ in the lungs, tubercles and ulcers are formed in the mucous lining of the bowels; hence comes an incontrollable Diarrhœa or Dysentery. From the same cause tubercles are formed upon the peritoneum, and tubercles and matter in the mesenteric glands; hence come Slow Peritonitis, and Ascites, and Marasmus. From the same cause Caries affects the bodies of the vertebræ; hence comes Lumbar Abscess.

All these are liable to arise in the course of Pulmonary Consumption; and the fatal event may be greatly accelerated in consequence. Not that, from arising in the course of it, they are to be regarded as merely incidental to it; for both it and they are all of the same essence, the several products of the same morbid constitution; sometimes one and sometimes another taking the lead; Pulmonary Consumption as often following these, as these following it.

Finally, then, Pulmonary Consumption is no more than a *fragment* of a great constitutional malady, which it would be in vain to think of measuring by the stethoscope, and which it belongs to a higher discipline than any mere skill of Auscultation rightly to comprehend.

ANOMALOUS CONDITION
OF THE
LARGE INTESTINE, AND OTHER VISCERA, IN A CHILD.

To the Editor of the Medical Gazette.

Sir,

A case of irregular development of the large intestine lately fell under my observation, which may not be unsuitable for the pages of your journal. It occurred in a little boy fifteen months old, who died after an attack of pneumonia, following pertussis.

On opening the abdomen no omentum was to be seen, nor any portion of intestine corresponding in situation to the transverse arch of the colon. The distended small intestine appeared to occupy the whole cavity, excepting that a portion of bowel, larger than the rest, was observed running across the hypogastrium.

From its size and direction I was led to conclude that it might be the transverse arch of the colon misplaced; but it had no longitudinal bands, and there was no omentum attached to it. On drawing it aside, it was found connected with the spine by a mesentery. The natural conclusion was, that it must be a portion of small intestine, unusually inflated, and deviating from its ordinary course; but, on tracing it on the right side, it was found to turn down over the sacrum, and to terminate in the rectum. On following its course to the left side, it proved to be continuous with the sigmoid flexure of the colon. On drawing the small intestines entirely downwards, the remainder of the colon was discovered; the transverse arch lying at the back part of the abdomen, flaccid and empty, with a small omentum attached to it. The deviation from the ordinary arrangement was thus found to consist in a secondary or inferior transverse arch of the colon, running from left to right, presenting some of the characters of small intestine, and furnished with a mesentery.

This mesentery, in proportionate size and general character, exactly resembled that of the small intestine, excepting that some of the glands lay upon the surface of the bowel, instead of being situated at a short distance from it. There was nothing remarkable in the contents of the bowels, but their coats were extremely thin.

Some portions of the lungs were condensed by inflammation, and these organs were extensively emphysematous; but the amount of morbid change was scarcely sufficient to account for the death of the patient. Several days before death, dyspnœa and the other symptoms of pneumonia had subsided, and the child appeared to die rather from failure of the vital powers than from positive disease.

Several of the appearances were characteristic of imperfect development; namely, a very thin calvaria, defective ossification of the anterior fontanelle, and an unusually large foramen cæcum, anterior to the crista galli; emphysema in the lungs, and atrophy in the intestines. The child had been very subject to diarrhœa; but during the last month the bowels were inactive, and required the frequent use of turpentine enemas. This was the sixth child, in a family of eight, which had died after a similar series of symptoms; but the bodies of the other children were not examined.

This case might naturally lead to a consideration of some of the theories which have been advanced on the subject of congenital malformation; and also of the speculations of Schultz on the function of the cæcum; but it is not my intention to enter at present upon these inquiries. I trouble you with an account of the case, because I am not aware that a similar variety has been distinctly recorded.

A new fact is always interesting; and although it may not, at first, seem capable of any very practical application, it is not unreasonable to suppose that, when compared with analogous facts, and associated with future observations, it may prove useful and important.

I am, sir,
Your obedient servant,
Theoph. Thompson, M.D.

Keppel Street, Russell-Square,
Dec. 28, 1835.

P.S.—The preparation is in the possession of Dr. Carswell.

ON THE CAUSES OF PROLAPSE OF THE FUNIS IN LABOUR.

By John Roberton, Esq.
One of the Surgeons to the Manchester Lying-in Hospital.

The manner in which this distressing accident takes place, has never, so far as I know, been adequately explained.

Early in the ninth month of pregnancy, the uterus is still high in the abdomen. As the period of parturition approaches, it descends. In some women this process of descent begins earlier than in others. Some have mentioned to me its commencement, as being observable to themselves, ten or twelve days before labour. In others the descent takes place chiefly in the ten or twelve hours preceding labour, and becomes accelerated when the hour of labour, as manifested by the *show*, nearly approaches.

This gradual, slow, painless descent of the gravid uterus is fraught with important uses. It is owing to this that the small end of the womb, containing the presenting part of the child, dips down into the pelvis, causing the head of the fœtus to present naturally (before the womb opens and the expulsive pains begin) in the position most favourable to its further descent, when the throes of labour shall actually commence.

Soon after the commencement of the labour pains, the head having been thus *located* in its natural position in the inlet of the pelvis, the os uteri opens, descends lower and lower, and the bulging part of the head, covered by the womb and the membranes and waters, comes to occupy and pretty completely fill the brim. If in this stage, during a pain, the waters escape, then the head of the fœtus instantly descends into contact with the lips of the womb, and closes the opening. So perfectly does the head occupy the os uteri from this stage forwards, that generally a portion of the waters is retained in the uterus, and passes off along with the child. Such is the mode by which nature shuts the mouth of the womb during labour, whereby its floating contents—viz. the funis and the remnant of waters—are kept from escaping into the vagina. It is true there is another cause which often helps to keep the funis from escaping before the end of the labour; I allude to its becoming twined round the neck, body, and limbs of the child. I will not undertake to say in what proportion of births the funis is discovered encircling once or more times the fœtal neck; but certainly this happens very often.

We are now prepared to understand how the prolapse of the funis may take place. The funis is a heavy rope; specifically heavier than the liquor amnii. Hence, when the waters escape, the funis, if nothing prevent—if the presenting part of the child do not occupy the inlet of the pelvis—sails into the vagina along with the current. If the patient is standing or sitting when the membranes rupture, this will increase the chance of the accident.

The next inquiry regards the circumstances which favour the descent of the funis: these will be far more impressively stated by cases than by mere description.

Case 1.—A patient of the hospital. Os uteri flabby, and not fully dilated. Six hours had elapsed since the escape of the waters; pains trifling; head presents high in the brim, having a number of twisted portions of the funis in advance of it, in contact with the scalp.

2. A patient of the hospital. Waters completely drained off; os uteri well dilated; no pains; a considerable coil of funis in the vagina, and the head resting at the brim.

3. A fold of the funis pulsated in the vagina. This passed down directly behind the pubis; between which and the head it was jammed. The bulging portion of the head occupied the inlet, and it seemed occupying its position firmly, for I could not move it upwards with my finger. The history I received of the accident was this: several hours before my visit, as the woman was standing by the fire, the waters passed off. On lying down immediately after, the midwife discovered the funis prolapsed.

4. Several hours previous to my visit, as she was kneeling by the bed, the waters escaped, when the midwife, on making her next examination, discovered the funis. The funis, I found, pulsated; it was very thick, and protruded a little beyond the os externum. There were no pains; the head lay at the brim.

5. Mrs. W., in the ninth month of pregnancy; so very large that her friends had the notion she carried twins. Early in the morning I found her having

slight labour pains, but made no examination. At breakfast-time the os uteri was not sensibly dilated. In about two hours after, as she was seated by the parlour-fire, a great discharge of water took place; not less than a gallon, according to the patient. In half an hour I arrived, and found the os uteri about half dilated, the head presenting, a hank of the funis in the vagina, and the labour going on.

6. Was called in the evening, by a professional friend, to a woman in Crown-lane. From midday there had been pains. At three in the afternoon she had been down stairs; and feeling a call of nature, as she was sitting in the act of obeying it, the waters suddenly escaped. The surgeon, on his arrival (several hours after this event), found the funis protruding from the vulva, and the head presenting at the brim.

7. Mrs. B. was taken in labour at two o'clock P.M.; pains trifling. At ten o'clock, as she lay in bed, the waters escaped in a very large gush. On examining immediately after, it was found by the attendant (I was not called till after many hours) that the funis was in the vagina, and that the head presented.

So much for descent of the funis in natural labour.

8. The waters had passed off when I paid my visit; a pulsating coil of the funis protruded from the os externum vaginæ. The shoulder presented. The funis, as I afterwards found, was three feet in length.

9. Evening. The patient had been in labour throughout the day; the hand of the fœtus was nearly at the os externum vaginæ, and the vagina was filled by a great many coils of the funis. The head was detected at the brim, but lying obliquely, resting on the top of the pubis.

10. The membranes presented a large bag, filling the brim, but no part of the fœtus could be detected. By and by a foot was felt through the membranes. These being ruptured, both feet and a large coil of the funis descended.

11. The waters had escaped ten hours before my arrival. The vertex rested at the brim, towards the right acetabulum. The right foot was down by the head, and a large coil of the funis pulsated in the vagina.

12. Found the feet in the vagina, and a doubling of the funis down between the thighs of the fœtus.

13. In this case the child had just been expelled, dead, when I arrived. It came footling, preceded by a portion of the funis.

Prolapse of Funis, occurring in Labours complicated with Pelvic Deformity.

14. Hand and funis in vagina; head also presenting naturally at the brim; promontory of sacrum encroaches on the antero-posterior diameter of the brim; rupture of the uterus; death.

15. Diminished antero-posterior diameter; funis in the vagina; head presenting naturally. Embryulcia.

16. Brim much contracted; head presenting; funis in the vagina. Embryulcia.

17. Antero-posterior diameter of the brim a little diminished, owing to a bony growth on the inner surface of the pubis at the symphysis; funis in the vagina; head forced by the pains into the cavity of the pelvis; rupture of uterus; death.

Concerning these seventeen cases, it is worthy of remark, that *in none did the presenting portion of the fœtus*, at the period when the nature of the presentation was detected, *occupy the brim in the ordinary manner:* either the head lay *at*, but not *in* the brim, there being no pelvic deformity, or the head could not enter the pelvis, owing to more or less deformity; or the presentation was preternatural (the feet, the hand, or the shoulder), and consequently unfitted, in reference to its bulk and figure, for filling the brim.

Again, it is further worthy of remark that, in addition to the above causes facilitating the premature escape of the funis from the uterus, in at least five of the cases I have related, the membranes ruptured while the patient was in a sitting or standing posture.

Of twenty labours complicated with prolapse of the funis, which have come under my notice within the last five years, in ten the head of the fœtus presented in a well-formed pelvis; in four the head presented, the inlet of the pelvis being more or less contracted; and in six the feet or the hand formed the presentation.

Of the fourteen labours in which the head presented, in two the uterus was

ruptured, causing the death of both mother and child; in two embryulcia was performed; in three delivery was effected by turning, two of the children being still-born, and one living; in three the funis was, by the hand of the accoucheur, lodged above the head, and the delivery trusted to nature, resulting in two children dead and one living; while in four, in which nothing was attempted to be done, all the children were still-born. In four of the six preternatural cases the children were living.

The mortality from prolapse of the funis, therefore, in my practice, has been great. Of twenty instances, in fourteen the children were still-born; and of the six children saved, two of these were footling labours.

The methods which I pursued with the view to saving the life of the child, were—

1st. *Turning.*—Mrs. B., extremely thin and delicate, the mother of several children, fell in labour at 2 o'clock in the afternoon. At 10 the same evening the waters escaped in a large gush, and a young surgeon, who was in attendance, on making his examination, found that the funis was in the vagina. Unthinkingly he suffered the patient to get out of bed and sit by the fire at times during the night. It was not till 5 the following morning that I was called, when I found the head presenting at the brim, and a doubling of the funis pulsating in the vagina. As the waters had entirely escaped, I was in some doubt what course to take; but finding there had been no pains since the rupture of the membranes, that the passage was relaxed and flabby, and that the woman was very patient, I introduced my hand into the vagina, and carried the cord upwards beyond the head. On discovering that this attempt did not excite pains, I thought it best to turn, which I effected with unexpected ease. The child, although feeble at first, in a few minutes revived perfectly.

Here the inirritable state of the uterus favoured turning, notwithstanding that the waters had escaped seventeen hours before. In general, turning, even so early as an hour after rupture of the membranes (the head presenting) is attended with great difficulty to the accoucheur, with much suffering and some danger to the mother, and commonly with destruction to the child. In such circumstances this method ought not to be resorted to. But should the accoucheur be in attendance when the waters give way, and immediately detect the funis, then turning is the best resource. In presentation of the funis with the shoulder, the operation may generally be expected to succeed.

2d. *Lodging the funis above the head.*—A patient of the hospital was the subject of this practice: the waters had escaped several hours before I saw her. I found the funis pulsating in the vagina in a great number of short turns; these passed down, in contact with the promontory of the sacrum, and, consequently, threw the head forwards on the pelvis. There was little or no uterine action. Having so generally failed in my endeavour to save the child in this kind of labour by turning, I resolved to try another method. Anointing my left hand with lard, I slowly carried the cord upwards, along the right side of the child's head, until it was fairly lodged above the head on the neck. Pains now came on, and every pain caused the cord to slip down a little, which I prevented with my hand as well as I could. At this period a dose of infusion of the ergot of rye was given, that probably helped to force the head down into the pelvis more rapidly than would otherwise have happened, whereby the funis was hindered from again descending. In an hour and a half a lively male child was born.

In two other instances I tried this same manœuvre, but without success. In one I thought I had succeeded in lodging the cord above the head, and out of the reach of undue pressure, but the child was born dead. In the other case, the waters having escaped, the head was so firmly fixed in the brim, that the cord ceased to pulsate during my persevering, but unavailing, efforts to return it. Nevertheless, with a moderate degree of dexterity, the funis may be now and then successfully reduced, as I learn from those of my colleagues with whom I have conversed on the subject.

3d. *Delivery with the forceps.*—I was called by one of the hospital midwives to a case of labour, described by her as "head, hand, and funis" presentation. Finding that the waters had passed off nearly ten hours before, and also that the parts were rather hot, I, previously to taking any step, introduced lard

freely. I now discovered that the vertex was presenting at the brim, towards the right acetabulum; that the right foot was down by the head in the right side of the pelvis, and a number of turns of the funis pulsating in the vagina down by the same side. As the pains were strong, and the waters had been so long drained off, I did not venture to bring down the feet, as I at first thought of doing, but pushed the foot up above the brim slowly between pains. The head soon began to enter the pelvis. I tried to pass the funis beyond the head, but did not succeed. I now left the patient for three hours; on returning, I found the funis protruding beyond the vulva, and still pulsating; the head had meantime descended a little, but more than half of it was as yet above the brim. I now again tried to reduce the funis, *i. e.* to lodge it above the head, but in vain, and therefore forthwith applied the long forceps, by which means, the head readily descending, the child was born alive.

In another case, which occurred about twelve months ago, I found the funis pulsating between the thighs of the patient, and the head of the fœtus pressing at the os externum. Not having the forceps with me, I was obliged to trust to the pains, aided by employing the fingers as an extractor. By the time the head was delivered, the funis had ceased to beat. With the help of the forceps or the lever, the child might easily have been saved.

Other modes of practice, besides those I have mentioned, have been recommended by various writers, some absurdly refined and fanciful, and others deserving attention. The reader will find them enumerated in most of the larger treatises on midwifery.

Manchester, Dec. 31, 1835.

ON THE "BRUIT DE SOUFFLET," OR BELLOWS SOUND, IN AUSCULTATION.

By Charles Cowan, M.D.

The "bruit de soufflet," or bellows sound, has been the subject of observation and experiment from a period very closely succeeding the discovery of auscultation; "but as to the connexion of this sound (says Magendie) with circumstances of plethora, whether general or local, with contraction of the cardiac orifices or nervous spasm, we know very little; we have not yet any sufficient data for determining the precise condition of the vessel in which the bruit de soufflet is heard."

It was at first regarded as almost pathognomonic of valvular disease, and considered to depend on friction, either from some morbid irregularity of the heart's surface, contraction of an orifice, or (as Laennec supposed) on a spasmodic condition of the muscular parietes of the heart. It has subsequently been discovered in the aorta and its ramifications, in cases of pericarditic inflammation, in certain examples of cerebral disease, and, what is still more interesting, as an almost constant phenomenon from the fourth month to the termination of pregnancy. These and other circumstances, such as bronchocele, aneurism, &c. in which the sound we are going to investigate is occasionally present, attach both an interest and importance to the subject which its first contemplation did not lead us to anticipate; while, at the same time, they afford materials for conjecturing its cause, and of attempting to generalize the conditions necessary for its production. It is for the elucidation of the last point that the present observations are more particularly intended.

And first it may be stated as a general principle, that the conditions requisite for the production of a physical phenomenon must necessarily be present wherever the latter may be found; and consequently all explanations, founded upon any peculiarity of structure or functions, must fail to be generally applicable, unless equally consistent with the phenomenon itself. Now since the bellows sound is known to exist elsewhere than in the heart, every explanation derived from the peculiar structure and functions of that organ can only be locally applicable, and is very possibly fallacious.

It results from the elaborate and ingenious researches of M. Bouillaud, in his admirable work on Diseases of the Heart, that, in nineteen cases out of twenty, where the bellows sound is observable, it depends on stricture of the cardiac orifices. The same pathologist has heard it where there have been

coagula in the ventricles; calcareous valvular vegetations or incrustations; a flabby and incomplete state of the valves; their adhesion to the cardiac or vascular parietes; dilatation of the ventricle and auriculo-ventricular orifice; considerable hypertrophy, with dilatation; in cases of copious hæmorrhage; and lastly, in nervous or chlorotic individuals.

Accompanying all these varied conditions, one common element may be traced—viz. *increased friction;* whether this is depending on constricted orifice, roughened membrane, increased rapidity of circulation, or on a want of normal proportion between the fluid and its containing tube. The variable intensity of the sound, its frequent subsidence and recurrence, and the uncertain morbid appearances discovered after death, are all easily explained, and satisfactorily prove that the mere presence of the bellows sound is of itself quite insufficient to indicate any certain morbid alteration with which it is invariably associated. Numerous accurate observations, particularly those of M. Bouillaud, seem to justify the conclusion that the rasping, sawing, whizzing, and hissing sounds, are only varieties of the bruit de soufflet; that they frequently replace each other, corresponding in their recurrence to modifications in the force and rapidity of the circulation. The correctness of these views is confirmed by the ingenious researches of Drs. Stokes, Graves, Law, and Mr. Main *, in cases of acute pericarditis. They clearly demonstrate that the deposit of coagulable lymph upon the surface of the heart and pericardium, distinctly gives rise to sounds closely imitating those taking place in the cardiac cavities, and presenting modifications which, as in the preceding instances, are evidently connected with the rapidity and impulse of the heart's contractions.

From the most gentle rubbing to the harsh and coarse rasping or whizzing sounds, corresponding variations in the number and force of the cardiac movements are observable, and the effects of depletion, either general or local, are immediately perceptible. The difference of friction produced by a fluid and that of the medium we have last adverted to, may naturally be expected to modify the nature of the sounds: this is, however, far less the case than might, *à priori*, have been anticipated; though we are inclined to the opinion that the peculiar rushing noise characteristic of the true bellows sound, whenever distinctly accompanying cases of pericarditis, depends either on valvular disease, unnaturally violent contraction, or hypertrophy, with dilatation of the heart;—at least such is the impression resulting from our limited experience; and in a case detailed by Dr. Stokes, where the bellows sound was unusually distinct, the morbid alterations to which we are alluding were found, after death, to exist *. Should this supposition be confirmed by additional experience, the power of distinguishing a sound produced by the motion of a fluid, from one depending on the friction of coagulable lymph, would not be either unavailable or uninteresting for increased accuracy of diagnosis.

In addition to the causes already enumerated, capable of exciting a bellows sound in the precordial region, there is one originating in conditions to which, we believe, we have first directed the attention of stethoscopists — viz. the action of the heart upon the lungs. The effect has been almost universally attributed to the pressure of the former on the thin layer of lung intervening between the left portion of the pericardium and the thoracic parietes; and the synchronism of the sound with the respiratory movements has been constantly mentioned as a sufficiently distinctive indication of its source. On the other hand, we believe it to depend on the mediate or immediate compression of one or more of the larger bronchi at the base of the lung, by an hypertrophied or dilated heart; a condition which, except in cases of extreme emphysema, is incompatible with the presence of the thin lamina of lung in the situation we have described. The bellows sound is also, in the circumstances we are supposing, synchronous with the heart's action, and cannot be distinguished from, or rather may be very easily confounded with, a bellows sound arising from some morbid peculiarity of the central organ of circulation itself. We

* Vide Dublin Journal, *passim.*

* Dr. Davies, in his Lectures on Diseases of the Chest, (MED. GAZETTE) by proving the frequency of valvular disease, and its sequel—hypertrophy, renders the dependence of the bellows sound on disease of the heart itself highly probable.

are satisfied, from two post-mortem examinations elsewhere detailed *, and from several living examples, that the seat of compression is one or more of the larger bronchi; and that when the obstruction is considerable, both the exit and entrance of the air are interrupted by the heart's action, and produce, as it were, a succession of short inspirations and expirations, synchronous with the pulse, and, when heard through the substance of the heart, closely resembling the bellows sound originating in the cardiac cavities. The similarity of these results should not excite our surprise, for the essential conditions of the bruit de soufflet are evidently present in the partially obstructed bronchus; where the air, entering with increased rapidity, in consequence of its volume remaining undiminished, impresses vibrations upon the bronchial parietes, precisely on the same principles as obstructed circulation reacts upon the heart or arteries.

The latter, when auscultated in their natural condition, manifest no other sound than a faint and distant murmur, depending upon the friction of the circulating fluid. By voluntary external pressure, this friction is increased, and we have a proportionate exaggeration of the normal noise, which may, at least in the larger arteries, be converted into a distinct bellows sound. The same effect would be the consequence either of accidental constriction or any increase of solid material, either from within or without, by which the calibre of the vessel is locally diminished.

If we auscultate an aneurismal tumor which involves some irregularity in the passage of the blood, a similar phenomenon is perceived; and if the internal arterial membrane becomes roughened by cartilaginous, osseous, or other deposit, the bellows sound is equally present.

The passage of arterial blood into a vein is accompanied with the same result. The bellows murmur, with some curious modifications, is also to be heard in chlorotic individuals; in cases where the heart's action is accelerated, or where the mass of circulating fluid has been suddenly lessened, in consequence of copious venesection. Dr. Fisher, of America (vide Medical Mag. No. 15), cites several cases where, by applying the ear to the head of individuals attacked with meningitis, a bellows murmur was distinctly to be detected; attributable, most probably, to the pressure of the larger arteries at the base of the brain, from the increase of fluid contents in a comparatively unyielding cavity; and perhaps also on some modification of the arteries themselves, which the researches of Dr. Alison prove to be dilated, when distributed to inflamed organs. We may mention, in confirmation of the correctness of this opinion, that the sound was diminished or suppressed, by either impeding or interrupting the circulation in the carotids. Dr. Graves (vide Dublin Journal, No. 16) details an interesting observation of acute pneumonia, where the bellows murmur was very distinctly heard over the portions of the chest corresponding to the affected lung: it no doubt originated in the larger arteries traversing the pulmonary parenchyma, since every precaution was taken, by that sagacious observer, to exclude sources of error in the diagnosis. In the increased impetus of the blood, the fact of capillary obstruction, and the improved conducting power of the lung, we may trace the necessary elements of the phenomenon.

A very superficial examination of the preceding examples, while it discloses various combinations of physical conditions, admits of their being classed under one common head—viz. of acting as obstacles to the circulating fluid; whether by presenting an unnatural outlet to the blood, producing irregularity of the lining membrane of the tubes, local alterations in their calibre, or a relative disproportion between their containing capacity and the volume of their contents.

The common effect would be increased vibrations of the arterial parietes, and the production of a sound more or less uniform in all.

The source of the bellows murmur in pregnancy is far less easily analysed, and has excited much greater diversity of opinion, than any of the preceding examples; but we think, that, by attention to the facts already adverted to, it may be proved to depend upon physical conditions equally simple with any to which we have previously alluded.

M. Kergaradec, who first directed attention to the subject, ascribed the bellows sound to the passage of the blood through the placental vessels;

* Vide Med. Gazette.

Laennec conceived it to originate in the uterine arteries; M. Paul Dubois, in the vascular system of the arteries generally; Dr. Kennedy, in the uterine arteries, aided, probably, by the circulation in the maternal placenta; and Dr. Forbes, in the uterine vessels corresponding to the portion immediately connected with the placenta.

These conflicting opinions point out the obscurity which has hitherto surrounded the investigation,—an obscurity to be ascribed, we believe, rather to the isolated manner in which the phenomenon has been studied, than to its intrinsic difficulties. One and all of the preceding hypotheses, supposing certain conditions in the uterine and placental circulation, which we cannot admit, might more or less satisfactorily account for the presence of a bruit de soufflet, but from their too great speciality, we do not hesitate to reject them, and to decide in favour of the opinion of M. Bouillaud, who conceives the placental murmur to result from the compression of one or more large vessels of the abdomen by the uterus charged with the produce of conception. In the first place, it is a general law of the circulation, that in proportion as the blood recedes from the heart, its progress becomes equal and continuous; and it does not appear probable that the impulse of the mother's heart should be propagated through the tortuous uterine or placental vessels, and still retain in their ultimate ramifications so distinctly an intermitting character as the nature of the bellows murmur would imply. Such a state of circulation would be different from any we are acquainted with in the structure of our different organs, and difficult to reconcile with the want of vascular continuity between the placenta and uterus, and with the now admitted independence of the fœtal circulation upon that of the mother.

Besides, under all other circumstances, with one doubtful exception, the bellows sound may be traced to some obstruction of the heart or arteries; and the nicest and most practised ear, as Dr. Montgomery says (vide Cyc. Pract. Med.; art. Pregnancy, p. 484), cannot detect any difference between sounds produced by these conditions, and those accompanying the pregnant uterus. This accurate observer has recorded a case of an enlarged sarcomatous uterus, where the phenomenon was heard in its most perfect form; also another example of an abdominal tumor compressing the aorta, where the murmur was equally distinct; and M. Bouillaud has observed it in the left iliac region in a female with a tumor in the ovarium, compressing the corresponding iliac artery. In addition to these facts, we may mention, that the same effect may be produced by external pressure with the stethoscope.

M. Bouillaud has succeeded in *displacing* the placental murmur, by making the patient lie alternately on the right and left sides; and in the only instance which we have had an opportunity of carefully examining since our attention was directed to this particular view of the subject, the same phenomenon was distinctly reproduced. These facts are incompatible with the hypothesis of the bellows sound depending on either the placental or uterine circulation, and to a certain extent invalidate the generally-expressed opinion, that the point of greatest intensity of the murmur is always identical in the same individual. But that this should literally be the case in the great majority of instances where the effects of change of position are not studied, would simply result from only the arteries of one side being compressed; and probability is greatly in favour of that pressure coinciding with the heaviest portion of the uterus, viz. that on which the placenta is attached.

The more diffused nature of the sound in the advanced periods of pregnancy, may be explained by the greater arterial surface exposed to the mechanical action of the uterus; and the fact of the murmur being occasionally audible for a short time after the placenta is detached, but instantaneously ceasing when uterine contraction has taken place, would in the first instance depend on the volume of the uterus not having materially diminished, and the cessation of sound, on the conditions necessary for pressure being removed. We may also advert to the fact, that the bellows murmur is never detected before the uterus has risen above the margin of the pelvis, or, in other words, until this organ would be capable of acting in the manner we have supposed; and all writers agree in describing the sound as most distinct over one or other of the iliac regions. The modifications in the nature of the murmur by the interrup-

tion of the fœtal circulation, by the removal of the placenta, by the death of the fœtus, may all be explained by accompanying changes in the volume and weight of the uterus. Lastly, as almost demonstrative of the opinion we are supporting, we have ascertained, after careful examination, that the bellows sound can be detected in the *femoral arteries*, immediately below the arch,—a fact in every respect analogous to what takes place in the large arteries of the neck, in cases of disease of the aortic valves. We have also found that the sound may, by change of position, be transferred successively from one femoral artery to the other, always corresponding with the side of the uterine murmur; and, lastly, that the sound is in every respect similar, though weaker and less diffused, to what is heard in the region of the uterus itself,—facts we should be unable to reconcile with any other hypothesis than the one we are endeavouring to establish.

The occasional presence of a bellows sound in cases of bronchocele of considerable size, is rather confirmative than opposed to the views we entertain,—the carotid arteries, in respect to the enlarged thyroid gland, being in exactly similar relations as the iliacs in reference to the pregnant uterus. The character and intensity of the sounds are in both cases modified by variations in the size and pressure of the tumor. We have recently examined a case of bronchocele, which placed the dependence of the bellows murmur on the conditions we are supposing in the clearest light. The central lobe was considerably enlarged, but gave not the slightest indication of sound to the stethoscope. The lateral lobes were less voluminous, but insinuated themselves on either side, beneath the sterno-cleido-mastoidæi muscles, producing a curved projecting appearance of the latter. On the right side, over a portion corresponding to the thickest portion of the lobe, and immediately over the carotid, a distinct and loud bellows sound could be heard, rapidly decreasing in intensity as the stethoscope was moved either upwards or downwards, but more especially in the latter direction. On the left side the phenomenon did not exist, the deeper portions of the lobe evidently not interfering with the calibre of the corresponding carotid. The absence of the sound over the heart was ascertained, and the possibility of artificially producing it by the pressure of the instrument on the carotid, not overlooked.

Dr. Forbes (art. Auscultation, Cyc. Pract. Med.) asks whether a bellows sound will be found to exist in active hypertrophies of other parts of the system? We would say *not*, unless conditions more or less similar to some of those we have insisted upon in the preceding examples are at the same time conjoined.

Having thus rapidly alluded to the various circumstances in which the phenomenon we are considering has been associated, we feel justified in concluding that, with one doubtful exception (pericarditis), it is every where depending on similar conditions, viz. on some impediment to the normal function of the heart, arteries, or air tubes, by which the circulating fluid is more or less obstructed in its course, and the parietes of the tubes thrown into unusual vibrations. A bellows sound is therefore indicative of obstruction, but alone is quite insufficient to point out the nature of the obstacle.

In medicine, as in every other science, it is always better to reason from the known to the unknown; and our present mode of viewing the question not only simplifies a hitherto somewhat obscure subject, but attaches it to a series of phenomena, the nature of which is both rational and easily understood.

M. Magendie, at one of his recent lectures, fitted a large syringe to elastic tubes of various diameters, and forced through them a quantity of fluid. A very distinct bellows murmur was produced, whence he concludes that probably the seat of the anormal sound resides in the parietes of the vessels themselves. In a portion of an elastic tube which had partially yielded to the impulse, the sound heard in the corresponding point exactly resembled that described by Corvisart as a symptom of aneurism of the ascending aorta. M. Piorry (vide Collection de Memoires sur la Physiologie, &c. 1831, p. 105, *et seq.*), to whose experiments M. Magendie makes no allusion, has also distinctly produced the bellows sound by means similar to the preceding, as well as by the forcible passage of fluid through the hand immersed in water,

and closed in the form of a tube. The sound was augmented by increasing the force of the current, and was rendered more intense by the presence of air mixed with fluid. In all his experiments there was a close analogy between the artificial sounds and those occurring in the heart and arteries. He was unable to imitate the rasping sound and its varieties, though Magendie appears to have partially succeeded, by increasing the roughness and hardness of the obstruction.

M. Cagniard Latour (says Dr. Williams, in his excellent work on Auscultation, third edition, p. 193), has succeeded in producing not only sounds, but musical notes, by the motion of liquids through tubes and apertures of different dimensions; and there can be no doubt of gaseous bodies acting in the same manner. Dr. Williams himself concludes that all the sounds in question depend upon "a certain resistance given to the blood moving with a certain force;" and this appears also to be the view of Dr. Hope and Dr. Spittal.

M. Raciborski (vide Man. of Auscult. Trans. p. 139) conjectures that the peculiar sound accompanying chlorosis may depend on the *quality* of the blood; but the argument in support of this opinion which he adduces, viz. that he has observed the sound artificially produced after very copious venesection, and again disappear when the blood had regained its qualities under the influence of tonics, cannot be regarded as in any degree confirmative, since *quantity* offers a far more palpable and natural means of explaining the effect, than the vague idea of change in quality. Whether this last condition is ever capable of modifying the sounds, we are unable to assert; the only analogous experiments we know of are in reference to gases, which produce different tones in their passage through glass tubes of similar diameter: but here the densities of aeriform bodies are far more disproportionate than can be imagined to exist in the most extreme modifications of the circulating fluid; and, moreover, both numerous experiments and observations on the living, prove that air, blood, and water, are all capable of originating sounds of a closely approximative, if not identical character. The possible influence of quality on the nature of vascular murmurs, is, however, yet undecided; and much obscurity still attends the precise explanation of the sounds characteristic of chlorosis.

Bath, Dec. 22, 1835.

THE DISCOVERY OF THE ARTERIES PRODUCING ERECTION OF THE PENIS IN MAN AND OTHER ANIMALS.

By Professor Mueller, of Berlin.

[From his "Archiv für Anatomie," &c.; the translation executed at Berlin, under the Professor's inspection.]

All that has hitherto been known of the anatomy of the penis is with reference to its general structure; its minute organization, producing erection, has been up to this period undiscovered. Neither Cuvier, Tiedemann, Moreschi, nor Panizza (although they have explained some details of the structure of the penis, viz. the venous arrangement producing the anastomosing chambers of the corpora cavernosa), have known the real and efficient part of the erectile tissue.

For a long time, continued investigations have given me more certain and important disclosures of the construction of this organ. Having already * treated of the fibrous substance which, in the horse, lies between the anastomosing veins, I will now communicate a more important part of my observations: it relates to those hitherto undiscovered arteries which, without doubt, are the proximate cause of erection,—a phenomenon which has hitherto remained so obscure and void of explanation.

The internal pudendal artery, after it has passed through the greater ischiatic notch out of the pelvis, and advanced through the lesser notch into its cavity again, gives off immediately the art. hæmorrhoid. externa; and then the arteria perinæi, its continuation, lies just within the inferior aperture of the pelvis, upon the tuber ischii and the ascending ramus of the os pubis; being accompanied by the vena pudenda interna and nervus pudendus, and covered by the lateral portion of the musc. levator ani. It then passes upwards, between the musculi ischio-cavernosus and bulbo-cavernosus. Whilst between these

* See J. Muller's Handbuch der Physiologie, p. 304.

two muscles it usually gives off the art. corp. cavern. urethræ, a branch which is almost as large as the continued trunk of the vessel. This continued trunk is the arteria penis; it passes between the before-named muscles to the back part of the root of the corpus cavernosum penis on its side; and, whilst extending over it, it divides into two branches, the art. *profunda* penis, and the art. *dorsalis* penis. The art. profunda penis penetrates the root of the corpus cavernosum from above inwards, and ramifies in it as the principal artery of the erectile tissue of the corpus cavernosum penis, carrying the blood which serves both for nutrition and erection. The art. dorsalis is continued over the corpus cavernosum of its side farther, even to the glans, lying on the outer side of the vena dorsalis penis, and having on its outside the nervus dorsalis penis. In this manner it sends, soon after the division of the original vessel, branches to the corpus cavernosum penis; and distributing itself to the fibrous envelope of the penis, its fascia, outer skin, and to the prepuce, it terminates by ramifying in the glans penis.

In the horse the erectile tissue of the corpus cavernosum penis is provided with double sets of arteries,—with a set from the arteria obturatoria, as well as that from the pudenda interna. The former, after it has passed through the foramen obturatorium, gives off a branch to the root of the penis, which not only supplies the musc. ischio-cavernosus, but also a twig which penetrates the inner part of the root of the penis, accompanied by a considerable branch of the nervus dorsalis penis. This vessel distributes itself upon the posterior part of the penis, whilst the continued trunk of the branch of the art. obturatoria, which supplies the penis, passes over its dorsum, and becomes the art. dorsalis penis, which sends additional twigs through the fibrous envelope of the corpus cavernosum into its erectile tissue. The arteria penis of the art. pudenda interna, therefore, of the horse, distributes itself in a totally different manner from the analogous vessel in man.

Its first division is the deep branch of the corpus cavernosum *urethræ*, from which also proceed twigs distributed to the corpus cavernosum *penis*, corresponding to the branches of the arteria profunda penis in man. The upper twig is very short, and unites itself with the art. obturatoria*.

The distribution of the principal branch of the arteria penis was all that was hitherto known of this important vessel: it is in the more minute distribution of its branches through the corpus cavernosum penis that the secret of the cause of erection has remained concealed. It is not a lucky accident, but a systematical arrangement, and investigations proceeding from certain combinations, that have guided me, in this instance, to an important discovery. It is generally thought that the arteria profunda penis, which nourishes the substance of the penis, is at the same time capable of filling the cells of the corpus cavernos. with blood during erection also; that the nutritive blood, as well as that serving for the purpose of erection, proceeds from the fine twigs of the same vessel into the fine (capillary) veins; that it passes inwards from these into the sinuous veins, and again from these to the vena dorsalis penis; and that the state of erection distinguishes itself from the ordinary state of circulation in this organ, partly in the quantity of blood circulating in its vascular net-work, and partly in an impediment offered to the return of the blood through the veins of the penis. The older writers, on the other hand, considered the sinuous veins of the corpora cavernosa to be cells;—imagined that the nutritive blood supplied by the ordinary circulation did not at all reach these cells, or pass through them, but was carried off by appropriate veins; and that still, during the state of erection, the cells of the corpus cavernosum were filled with blood. Both views are, as we shall see, incorrect. The opinion of the old writers is proved to be unfounded, as well by investigations on the dead body as by the vivisections of beasts. In many experiments performed on the living horse, dog, ram, &c., I have observed, that upon making an incision in the corpora cavernosa, these bodies were not, in their unexcited state, much charged with blood, but that blood is contained in their sinuous veins, although certainly in less quantity than in the corpus cavernos. urethræ, which bleeds freely when cut across. Farther, in the majority of human subjects blood

* See Gurlt Handbuch der Vergleichenden Anatomie, 2 Bd. p. 281.

is found in the sinuous veins of the corpora cavernosa penis.

With regard to other views, I had, through different experiments and anatomical investigations, brought it to the highest step of probability that the cause of erection did not lie in the mere checking of the blood in the vena dorsalis penis, but that it must be hidden in the tissue of the penis itself. This view had increased to that degree which involuntarily leads us to prosecute an idea through all difficulties of investigation.

I resolved now to apply to the arteries alone those injections which I had hitherto directed principally to the veins. The idea that the vessels which poured out blood during erection differed from those which passed it over to the veins forming the capillary net-work (serving the purpose of nutrition), had haunted me already a year. The want of success that had so long attended my injections had almost deprived me of all hopes, when the long-expected discovery was made. It was whilst drawing up a memoir on the erectile tissue and erection, for the Encyclopædial Dictionary of the Medical Sciences, published at Berlin, that this idea presented itself to me, and induced me lately to make new and finer injections of the arteries. It was one of the happiest days of my life when I repeated this injection on a human penis, through the arteria profunda,—it led me to the discovery of the wonderful difference in the distribution of the fine twigs of this artery. Both sets of branches, as well those which nourish the corpora cavernosa penis in their internal structure as those which form scrolls during erection, are derived from the art. profunda, and are given off from it during its course through the spongy tissue. These two sets of vessels differ from one another as much in their size as their course, their form as in their object.)

I. *The nourishing Twigs (Rami nutritii Arteriæ profundæ Penis.)*

When an injection of the arteries of the penis is made with size and vermilion, a considerable portion of the injected mass is always forced into the cavities of the corpora cavernosa, as well in the human organ as in that of the horse and dog. When this mass of injection (of which I am still uncertain as to the means by which it enters into the cellular structure) is washed out, the rami nutritii will become evident. The rami nutritii of the spongy substance (which, since they are upon the walls of the sinuous veins in the interior of the penis, may be also called the vasa vasorum) are found to be as minute as the arteries of any other part: they distribute themselves upon the pillars of the spongy substance, until they become too fine to be perceived by the naked eye. As in the arteries of other parts, they anastomose; and lastly, they form, as in other parts, the capillary net-work which is so difficult to be injected in the penis, owing to the facility with which the injection escapes into the cavities of the corpora cavernosa.

II. *Arteriæ Helicinæ Corporis cavernosi* (in Man.)

In order to see these arterial branches satisfactorily, an injection composed of size and vermilion must be thrown into a separated penis, through the art. profunda. (In the horse the pudendal and obturatorial artery are to be injected together.) As before mentioned, a part will escape into the cavities of the corpora cavernosa. When the injection has become cold, the corpora cavernosa must be cut open longitudinally, and that portion of the injection which has escaped into the cells is then to be washed out with great care. If a size of a greater degree of consistence has been employed, it will be found to have become solid on cooling. In this case the penis must be soaked in water, and the mass squeezed out softly and carefully, until the cellular tissue is emptied. When a thin size has been used, this will, of course, not occur; then washing alone will be sufficient.

If the tissue of the corpora cavernosa be now examined with a magnifying lens on its posterior third, it will be seen that in addition to the distribution of the arteries already described, there is another class of vessels, having an entirely different form, size, and distribution; these branches are short, being about a line in length, and a fifth of a millimetre in diameter; they are given off from the larger branches, as well as from the finest twigs of the artery. Although fine, they are still easily to be recognized with the naked eye; they come off from the artery mostly at a right angle, and projecting into the cavities of the spongy substance, they

Fig. 1.

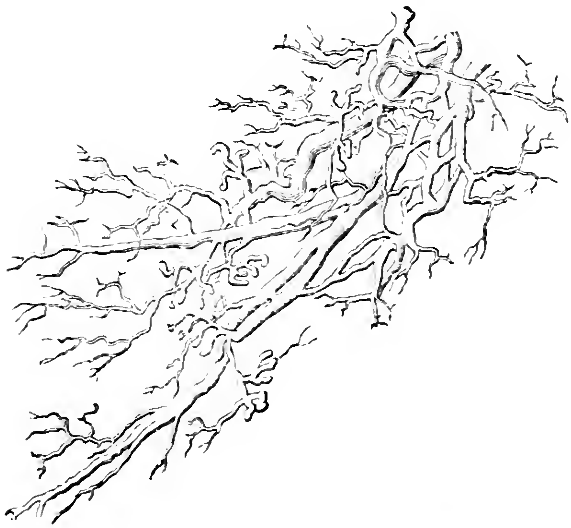

Fig. 3.

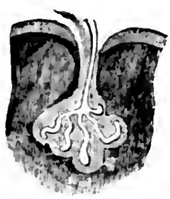

Fig. 2.

Fig. 4.

Fig. 1 is a representation of the arteriæ helicinæ, as they appear in the corpora cavernosa of the stallion. It will be observed here that in some instances nutritive twigs arise from these vessels, a circumstance which does not occur in man.

Fig. 2 is a drawing of a very highly magnified portion of the arteriæ helicinæ, taken from the posterior portion of the corpus cavernosum urethræ of man.

Fig. 3 shews a single bunch of these vessels, with its envelope.

Fig. 4 represents a portion of the art. profunda penis (in man), with its attached vessels, somewhat enlarged.

either terminate abruptly, or else swell out into a club-like process, without again subdividing.

In the penis of the stallion these vessels must be sought after in the root of the corpus cavernosum penis, in preference to the other parts, since, as the injection succeeds better here, they will appear entirely perfect.

In the dog they are evident in the entire structure, but they are at the same time very difficult to be sought after, on account of the innumerable tendinous fibres which pervade the whole of the spongy bodies.

In the horse they are likewise difficult to be discovered, with the exception of the corpus cavernosum urethræ; but in man they are the easiest; and the human penis also possesses the most peculiar structure.

The following description relates to the penis of man. These twigs branch off from place to place, sometimes alone, sometimes in greater number: little bundles will be seen, in which from three to ten twigs stand together; these, as well as the former, project constantly into the cells or venous cavities of the corp. cavern. penis. When the arteries thus form a tuft, they arise by a common stem, which immediately divides itself into the separate branches. Sometimes such a vessel, whether it proceeds from the artery as a single branch, or forms part of a cluster, divides itself into two or three parallel branches, which also end either abruptly, or else swell out near their extremity.

Almost all these arteries have this character, that they are bent like a horn, so that the end describes a half circle, or somewhat more. When such a branch so divides itself, there are formed doubly bent twigs, inclined one to the other. I have before observed, that many of these arteries enlarge towards their end; this enlargement is gradual, and is greatest at some little distance from the extremity, so that the end is somewhat conical. This cone, however, is rounded at the point, and, giving off no branches, terminates immediately. The diameter of these twigs, in their middle, is from the fifth to the sixth of a millimetre: they preserve a great similarity: thus those which branch off from the large trunk of the artery are not thicker than those which take their origin from the finest subdivisions. (See fig. 4.) Indeed, the finest twigs of the art. profunda often evidently give off branches of this kind, which are much thicker than the vessel from which they arose.

These remarkable vessels possess throughout a great similarity to the tendrils of the vine, except that they are much shorter in proportion to their thickness; therefore I have named them the "arteriæ helicinæ." Their termination may be also compared to a crosier. By a more minute examination of these vessels, either with a lens or a microscope, it will be perceived that although they at all times project into the venous cavities, yet they are not entirely naked; but it will be seen that they possess a delicate membranous covering, which, under the microscope, appears to be granular. (See fig. 3.) After a more forcible injection this envelope is not visible. When the arteries form a bundle, the whole is covered by a slight gauze-like membrane.

I found within the venous cells of the posterior part of the corpus cavernosum urethræ small clusters of these arteriæ helicinæ, in which the thickness of the soft mass surrounding each artery was much greater than the calibre of the inclosed vessel. (See fig. 2.) Perhaps this difference arises from the circumstance of these vessels not being sufficiently distended with the injection mass. In this case the arteries appear finger-shaped. The ends of the processes were less bent upon themselves than was the case in the art. helicinæ of the corpora cavern. penis. Still the arteries contained in these finger-form masses were invariably bent upon themselves within the soft substance, so that the somewhat pointed end came nearer to the surface, without having an aperture. I know not whether this covering consists of the inner, and here much attenuated, skin of the veins forming the cells of the corpora cavernosa penis; I doubt it, and conjecture that these coverings perform a very important part in producing the phenomenon of erection.

Our arteries have no openings which can be detected, either on their surface or at their extremities; and if the blood, as it is probable, proceeds from them during erection in greater quantity into the cells of the corp. cavernosa, so it

must either pass through invisible openings, or, at least, through openings which only become enlarged by the great extension of the vessels. If the great number of these tendril-like branches which are given off from the art. profunda penis be considered in comparison with the many fine nutritive twigs of the same vessel, it must be evident that when the former are filled, they must take up by far the greater portion of the blood conveyed by it. The diameter of the art. profunda, therefore, not only includes the nutritive twigs which arise from it, but also the tendril-like branches, which likewise deriving their blood from it, yet, it is probable, allow none to pass except during erection; therefore the blood in the unexcited state of the penis only pervades the nutritive branches, and thus only reaches the commencement of the venous cells in smaller quantities; whereas, during erection, it is probable that the blood passes in quantity through these tendril-formed vessels into the cells.

Many of our attentive readers will perhaps imagine that these vessels, instead of terminating, do more probably form loops, which, turning upon themselves, become venous, as those looped vessels which were discovered by E. H. Weber to penetrate the villi of the placenta, and project within the venous sinuses of the uterus. But this is not so. Our vessels are simple; they bend themselves at the end, but they do not return to their trunk as a loop, but are simply blood-containing processes of the arteries, which project freely into the cellular cavities of the veins of the corpora cavernosa. These veesels are most numerous in the posterior part of the corpora cavernosa penis; in the middle and anterior parts they occur but seldom. They are also present in the corp. cavern. urethræ, especially in the bulb; anteriorly here, also, they become less frequent, and, as yet, I have not clearly perceived them in the glans penis. They are much more difficult of detection, however, in the corp. cavern. urethræ than in those of the penis, where their demonstration, especially in the human penis, is very easy.

The greater development of these arteries in the posterior part of the organ corresponds with the fact of erection being always earlier evident there, as if the blood distributed itself from thence into the venous cells.

The preceding description is entirely confined to the human organ. It was in man that I first attempted to discover the anatomy of these vessels, and here they are most easily seen. The tendril-formed vessels are indeed present in the penis of other animals, but are in them much more difficult of demonstration than in man; their form corresponds mostly with those of the human penis, especially in the apes, where I have investigated them in the simia sylvanus. In other animals they are very irregular, as, for instance, in the dog, and in the corpus cavernosum urethræ, and the posterior part of the corp. cavern. penis of the stallion; for they frequently give off from their side many nutritive twigs; and we can only compare the free obtuse ends, or processes which remain undivided, with the tendril-formed arteries of man. (See fig. 1.)

The importance of this discovery in explaining the phenomenon of erection must be perceived by every one. In the meantime we will not enter into a theory concerning its cause, but leave the reader rather to pursue its further process himself, on the ground of our researches.

EFFICACY OF CHLORIDE OF ZINC

IN THE TREATMENT OF MALIGNANT ULCER.

To the Editor of the Medical Gazette.

SIR,

I HAVE much pleasure in presenting to the public, through your valuable journal, the following case of malignant ulceration, successfully treated by the chloride of zinc, on the principles explained in my two papers, published in the Medical Gazette of December 12th and 19th.

The patient, Ann Whaller, aged 55, of impaired constitution, has been, since the 21st September, 1835, under the care of Mr. Howship, at the Charing-Cross Hospital, for an ulcerated state of the integuments of the chin and upper lip, of an extremely obstinate nature. The affection had commenced about eighteen months previously, in the form of a small tubercle, or pimple, on the chin, which, from being irritated with

the finger, ulcerated, and showed no disposition to heal. She became, in consequence, an in-door patient of St. George's Hospital; from which, after some time, she was dismissed relieved. The disease subsequently returned in an aggravated form, which induced her to obtain admission into the Charing-Cross Hospital, at the above date. As arsenic and the other remedies which had been employed were productive of only temporary benefit, I applied the chloride of zinc, by the kind permission of Mr. Howship, on the 29th November, when the following appearances were observable. On the left half of the upper lip, extending to the ala nasi, there was an ulcer of the size of a half-crown. Its margins were hard, and somewhat elevated; its surface had a dirty-grey aspect, and emitted an offensive sanious discharge. There was another ulcer, which occupied the principal part of the chin, similar in character to the above, but with more extensive hardness of the surrounding integuments, which had a livid-red hue. Nearly the whole of the under lip was destroyed, causing a permanent exposure of the alveolar ridge, and a constant trickling of saliva; giving a hideous appearance to the patient. Both sores were the seat of acute pain.

November 30th.—Complained of considerable pain, in consequence of the application of the paste; but as she is habitually querulous, little stress was laid on the circumstance. On removing the chloride of zinc composition, the dry greyish-white eschars, characteristic of the chloride, were observed.

Poultices ordered.

December 2d.—Slough has come away from the chin. She acknowledges herself to be free from pain in the parts. Eschar on the upper lip getting detached round the edges.

Continue poultices.

7th.—The slough on the upper lip separated the night before last, and has left a very healthy granulating surface; all surrounding hardness has disappeared. As there still remained considerable induration round the sore on the chin, the application of the paste was renewed to this part.

Simple dressing.

10th.—Ulcer on upper lip quite healed.

12th.—Slough has separated from the chin, leaving behind a well-conditioned sore.

18th.—Ulcer much smaller; continues daily improving.

Strips of adhesive plaister to be applied.

24th.—Sore nearly cicatrized.

Continue the dressing.

The rapid amendment which followed the application of the chloride in this case, is the more remarkable when we take into account that the woman's constitution had been previously undermined by the inroads of vice and disease.

Several other cases are now in progress, of which the results will be duly reported.—I am, sir,

Your most obedient servant,

ALEXANDER URE.

ELECTRICITY AND THE NERVOUS INFLUENCE.

A Final Reply to Dr. Williams,

BY DR. WILSON PHILIP *.

[With this letter the discussion between our respected correspondents must be allowed to drop.—ED. GAZ.]

To the Editor of the Medical Gazette.

SIR,

DR. WILLIAMS is particularly unfortunate in accusing me of errors, in a reply in which (a result I was little prepared for) there is hardly a paragraph free from inaccuracies. Had I been sooner aware of such a possibility it would have saved us both a good deal of trouble†.

He quotes my observation as erroneous, that the electricity of electric animals is incapable of affecting the common elec-

* *Errata in Dr. Philip's last paper.* — Page 444, 2d column, line 15, *before* "which," *insert* "the functions of."—Page 445, 1st column, line 23, *for* "body," *read* "blood."— Ibid. line 42. At the end of this line there should have been a reference to the following note:—This observation applies equally to the organs of the nervous as to those of the other powers of the living animal. It is by their peculiar mechanism that they are enabled to supply and direct the agent on which all the nervous functions, properly so called, depend.

† Dr. Williams accuses me of having modified my expressions. He should have stated what the modification is that he refers to: I am not sensible of the slightest modification of any of them.

trometer*. The word "common" is omitted by Dr. W., which wholly alters my meaning. This may be an error of the press; but the following must be an error of Dr. Williams. He refers to Dr. Davy's papers on the Torpedo, in the Philosophical Transactions, for a refutation of my statement. Dr. Davy's words are,—

"In accordance with Mr. Walsh and my brother, I have in no instance seen the torpedo affect the common electrometer, or exhibit any, the slightest, indications of a power of attraction and repulsion in air." (Phil Transactions for 1832.) And in his last paper on the same subject, in the Phil. Trans. for 1834, in enumerating the resemblances between the electricity of the torpedo and that of inanimate nature, he does not mention the former affecting the common electrometer,—a proof that he still found the fact as he had before stated it. Here are all the latest authorities on the subject.

These facts are surely sufficient to prove my position, that even the electricity peculiar to what are called electric animals, respecting which there is no difference of opinion, is modified by the other powers of the living animal; which renders altogether inconclusive the arguments of Dr. Williams, derived from the properties of the electricity of inanimate nature.

Dr. Williams, I think, will hardly, on reflection, adduce such cases as he states, where so many chemical affinities are operating, as proofs that oxygen and carbon will combine by mere juxtaposition. Let him for a moment consider how much is necessary to make such cases serve such a purpose.

Be this as it may, it cannot, as far as relates to animal temperature, affect my position, resting, as it does, on direct experiments; from which it appears, that when the nervous influence is wholly withdrawn, the process which supports animal temperature ceases; and that when this influence is partially withdrawn, that process is impaired exactly in proportion to the degree in which it is withdrawn; and, lastly, that after it is wholly withdrawn, the temperature of living arterial blood is immediately raised several degrees by subjecting it to voltaic electricity, which has no such effect either on dead blood, whether arterial or venous, or on living venous blood, that is, living blood which has undergone the action of the nervous influence.

With respect to what is said in the latter part of the same paragraph, has Dr. Williams ascertained that all combustion is not the effect of electricity? On this head he will find Dr. Faraday rather a formidable opponent.

Dr. Williams could not have so mistaken me as he does in the paragraph marked 1, and the note appended to it, had he read my reply, in the Philosophical Transactions for 1829, to MM. Breschet and Edwards, whose authority he adduces against me. Above five years have now elapsed without any attempt on their part to maintain their former statements; and with regard to the latter part of the same paragraph, it must have been hastily written. Dr. Williams will not surely maintain that there are no circumstances but the feebleness of the power which can prevent electricity becoming evident to our tests.

The most unlooked-for inaccuracy of Dr. Williams, however, is, that even at this, the eleventh hour, he is not aware of the foundation on which my inference rests; although, I think, it will be admitted that I have explained it with sufficient care. No man, in the least acquainted with the subject, could infer the identity of the nervous influence and electricity, merely from the circumstances enumerated in the paragraph marked 2, as the foundation of my opinion.

Dr. Williams reminds the reader that the electric organs are peculiar to the animals called electric. For this, of course, we are prepared, as other animals do not possess their peculiar faculty; but in such a discussion as the present, he should have added, that these organs, in a great degree, consist of nervous matter; that is, of what belongs to all the more perfect animals. Dr. Davy, who examined them with great accuracy, says, in his first paper, page 265, "Their great proportional size, the vast proportion of nerve with which they are supplied," &c.; and in page 269, he says, the electric "columns formed of tendinous and nervous fibres, distended by a thin gelatinous fluid," &c. From

* Medical Gazette, for Dec. 12, p. 396.

both passages, it is a necessary inference that nervous matter is essential to their function.

But the most important fact relating to the peculiar faculty of electric animals, the electric nature of which is universally acknowledged, is that, like the other nervous functions properly so called, it is immediately dependent on the brain. Dr. Davy, in his last paper, observes, "When the brain has been divided longitudinally, the fish has continued to give shocks; when the brain has been entirely extracted, the fish instantly lost this power, though the muscles generally continued to act powerfully."—P. 546. That is to say, that the electric power is not, like the muscular, independent of the brain, but, on the contrary, immediately dependent on it,—proving that in this, as in the other nervous functions, as shewn elsewhere *, the nerves are the passive, the brain and spinal marrow being the only active, parts of the nervous system. I need not say how powerfully this fact countenances the inference which is the subject of the present discussion. It is gratifying to see that here, as generally happens, when truth is once arrived at, other facts, beside those which conducted to it, arise to give it their aid.

Dr. Williams states that in one of my experiments the animal died in consequence of the electricity in two hours and a quarter, and gives this as a reason for believing that it does not prove fatal by exciting inflammation of the lungs; but he neglects to state that in this instance the subject of the experiment was a dog, which is much less tenacious of life than the animal (the rabbit) the usual subject of my experiments, which sometimes survived the effects of the electricity nearly twenty hours; but the most material oversight here is, that he quite forgets that inflammation must be much more rapid in its fatal effects when the cause which produces it continues to be constantly applied, than where, as in ordinary cases, the operation of the cause of the disease ceases at its very commencement. The proofs of the inflammation from the effects of the electricity being the cause of death in the cases referred to, are very simple. The animals died of oppressed breathing; and on dissection it was found that the only cause of this symptom was the inflamed state of the lungs. But enough of the ungracious task of pointing out misconceptions.

For misconceptions all must be prepared who attempt to correct prevalent errors, which always tend, in proportion as they interest the feelings, to impede the judgment. We do not readily forego opinions for which we can quote a list of authorities; but having so fully explained myself on the present occasion, I did not expect such misconceptions as some of those I have pointed out.

Dr. Williams, in our long discussion, has given dissertations on electricity, and on some of the powers of the living animal; and he has referred copiously to the prevalent opinions of the day, without much discrimination respecting his authorities. He calls my inference an hypothesis, and very inaccurately compares it with the systems of Brown and Broussais, to which it has, neither in its nature, or its object, nor in the foundation on which it rests, the slightest resemblance. All this may make an impression on the ill-informed; but I ask any one who has seriously considered the subject, if he can extract either from Dr. Williams's original strictures, which produced the present discussion, and which, the reader must perceive from many parts of the discussion, were adduced with a very imperfect knowledge of my publications on the subject,—or from his numerous replies, one sentence fairly bearing on the points at issue, and to which I have laboured in vain to direct his attention.

I have been allowed to maintain without contradiction the following positions:—

1. That a living power, properly so called, can exist in no texture but that to which it belongs in the living animal.

2. That none of the powers of inanimate nature are capable of the functions of a living power, properly so called; and lastly (a position equally supported by the properties of a living power properly so called, and direct experiment),

3. That no analogy can be observed between the functions of a living power,

* See the first of my papers in the Philosophical Transactions for 1829.

properly so called, and the operations of the inanimate world, except where some of the agents of that world co-operates with it.

To my original inference I therefore recur, namely, that the result of the experiments being admitted, the identity of the nervous influence and voltaic electricity is a *necessary* consequence; because if this be denied, we must admit that there are two distinct principles, the one of which possesses all the properties of the other; and I believe that those, whose minds are practised in such subjects, will allow that no more conclusive proof of any inference can be adduced; and that none of the positions which have been brought against it can in the least degree affect it.

I am, sir,
Your obedient servant,
A. P. W. PHILIP.

St. Thomas's Hospital Reports. By JOHN F. SOUTH, Assistant Surgeon. No. I. *Nov.* 1835.

Guy's Hospital Reports. No. I. January, 1836. Edited by GEORGE H. BARLOW, M.A.; and JAMES P. BABINGTON, M.A.

THE medical staff at each of the Borough hospitals has come to the determination of publishing "Reports;" and we are glad to find that the results of an extensive field of practice are thus likely to be open to the profession—that is, so long as such reports continue to be published; a period, however, which we suspect will not be very long, unless the undertaking be merged in the general concerns of the hospitals respectively, and the disbursements supplied from their funds. We do not mean by this to imply any unfavourable opinion of what the parties have done, or are capable of doing, but simply that the experience of the nearest approximation to such works, namely, the Transactions of the Medical and Chirurgical Societies of London and Edinburgh, afford no room for flattering anticipations of the result. The former of these was supported by the chief persons engaged in the present works; to whom were added not only their metropolitan brethren, but the practitioners of all England; yet we refer to the accounts of the society in proof of the fact, that they never have attained a remunerating sale. Again, as to the Edinburgh Transactions, they died a natural death, having reached only the second volume. We must hope that a better fate awaits the "Reports" before us.

With which hospital the idea originated we know not. The gentlemen of St. Thomas's appeared first in the field; and we have heard that on this their rival neighbours immediately took the alarm, and got up opposition "Reports." Be this as it may, we shall be perfectly candid and impartial between them, and, in fact, as will be seen, can bestow unqualified approbation upon neither.

In the Reports from Guy's Hospital (of which, though published last, it suits us to speak first), we have too many old cases—cases, indeed, which have been already published, particularly those of aneurism, not really by Sir Astley Cooper, as the advertisement led us to expect, but taken from Sir Astley Cooper's notes. It is true that accounts of two dissections are added by Mr. Cock, but the papers contain nothing else of any importance not to be found in Sir Astley Cooper's papers in the Medico-Chirurgical Transactions on these very cases; and we are reminded by their reappearance of a remark made by Sir Astley Cooper (in his paper in the fourth volume of the Medico-Chirurgical Transactions, page 434); viz. that

"The iliac artery has now been so frequently tied for aneurism of the femoral artery at the groin, that no useful purpose can result from the narrative of a case of that kind offering no uncommon circumstances."

Had the cases been recent, their publication would have been very right; but, under the circumstances, their introduction is, we think, injudicious. Now we have no doubt that our friends at Guy's will say this is very ill-natured; but if they will be advised by us, they will not give room even for a suspicion of paucity of materials by go-

ing back more than twenty years for cases, the chief details of which have been long before the public.

We also doubt the propriety of introducing into "hospital" reports so many cases which occurred in private practice, as we find in the brochure before us; this, at all events, is at variance with the appellation of the work, which ought rather to be called, "Reports of Practice in Guy's Hospital and elsewhere." Thus, in an interesting paper by Dr. Bright on diseases of the arteries of the brain, of eight cases given in illustration, *six* are from his private practice, *two only* having occurred in the hospital! Again, there is a want of statistical information. Indeed, we have no information as to prevalent diseases or general results, except with regard to midwifery by Dr. Ashwell, and revaccination by Dr. Babington. Of the general business of the hospital, as to admissions, recoveries, deaths, &c. &c. we have not a word. All these objections, however, so far as they may be found valid, will be easily remedied: meantime, we shall endeavour to farther the objects of the work by laying before our readers, from time to time, some of the most important observations it may contain.

Dr. Bright on Fever.

Dr. Bright's views have undergone very essential modification regarding the treatment of fever. We shall first give a case in illustration, and then proceed to some farther remarks.

" *Case of Simple Fever, protracted by Irritation of the Bowels, and attended by Relapse.*

Henry Grant, aged 14, was admitted under my care August 12, 1835, on the fourteenth day of fever. He stated that he was attacked with headache, shivering, and pain in his back, while at work; and the symptoms he described were, in all respects, those of a simple continued fever. At the time of admission, he was greatly oppressed with symptoms of acute fever; skin very hot, and covered with miliary eruption; pulse 130, feeble, but sharp. He said he had no heachache, but had a tendency to wander. His bowels were relaxed, and there was some tension of the abdomen; tongue dry, brownish in the centre, white at the edges; no cough.

Radatur caput, et applicetur Embrocatio communis. Habeat Sodæ Carbonatis, gr. x. ex Julepo Menthæ, sextâ quâque horâ.

13th. — Aspect improved; tongue moister, and less furred; skin pungently hot; pulse 120. He has not the least cough, nor any pulmonary symptom. Three watery yellow stools, sinking to the bottom of the vessel.

Adde Vini Opii, ♏iij. singulis dosibus misturæ. Applicetur Cataplasma Lini ampl. abdomini. Injic. Enema Amyli c. Syrupi Papap. alb. ℥ss. horâ somni, urgente diarrhœâ.

14th.—Pulse 108; abdomen less tender; motions very loose and gritty, but only two in number.

Rep. medicamenta.

15th. — Pulse 92; skin hot; one loose stool of the same character.

Rep. medicamenta.

17th.—Pulse 96; skin hot; bowels open as before.

Rep. medicamenta.

19th.—It appears that the injection has been omitted the last two or three nights.

Injic. Enema Amyli c. Syrupi Papav. alb. ℥iij. omni nocte.

20th. — Dejections still very loose; but a portion of the fæces has changed its character, and floats on the surface. Pulse 92; skin less hot; tongue gradually cleaning.

21st.—A slight feculent motion, with some tenesmus. Pulse 80, rather weak; skin temperate. He has been sick, after taking nourishment.

Habeat Sodæ Carbonat. gr. x. Spir. Lavend. comp. ℥ss. ex Julepo Menthæ, sextâ quâque horâ. Omitt. Enema.

22d.—Motions to-day nearly natural. He is better in all respects.

Rep. medicamenta.

24th.—Motions not quite so healthy.

28th.—Omitt. Cataplasm. Lini. Repetantur alia medicamenta.

Sept. 4th.—Habeat Infus. Cascarillæ c. Sodæ Carbonat. gr. xv. ter die.

He now appeared to be quite convalescent; and as he expressed a great de-

sire for animal food, a small quantity was allowed.

18th.—He has suffered a relapse; bowels relaxed; the dejections not natural; skin hot; pulse 120; tongue furred; some cough.

> Hydrarg. c. Cretâ, gr. iij. statim. Sodæ Carbonat. gr. x. c. Vini Opii, ♏iij. ex Julepo Menthæ, sextâ quâque horâ. Low diet.

> 19th.—Applicetur Cataplasm. Lini abdomini. Hydrarg. c. Cretâ, gr. ij. horâ somni. Rep. mistura.

22d.—The irregular and unnatural state of the bowels remains.

> Hydrarg. c. Cretâ, gr. ij. Pulv. Ipecac. comp. gr. iij. horâ somni. Rep. mistura.

28th.—He has improved decidedly, and his febrile symptoms are gradually diminishing; but he complains of a pain and tenderness in the left iliac region.

> Applicetur Emplast. Cantharidis parti abdomini dolenti. Habeat Liquoris Calcis, ℥iv. quotidie c. Lacte. Omitt. alia omnia.

He was kept enirely in bed, and strictly upon a mild milk diet, taking liquor calcis with his milk, till the 19th of October; during which period he took two doses of three grains of the hydrargyrum c. cretâ, each followed by two drachms of castor oil. His motions having now gradually acquired a healthy appearance, he was allowed two eggs and some beef-tea daily; and on the 30th he left off all remedies, but continued in the hospital a week longer, to protect him from the danger of relapse; and left it at that time, full of flesh, and healthy in his appearance."

Now, it will be perceived that the treatment here adopted differs from that of most practitioners, and from that formerly recommended by Dr. Bright himself; the difference consisting in the almost complete abandonment of mercurial preparations; for it will be seen, that during the first attack of fever not one particle of this medicine was used, and during the second only a few grains of the hydrar. c. cretâ. The difference between Dr. Bright's previous and present practice will, however, be best seen by contrasting parallel passages from his works. In his "Report of Medical Cases" Dr. Bright says,—

"In fevers in which the irritation of the lining membrane of the intestines is most prominent, we often have a relaxed state of the bowels from the very commencement of the disease: but more frequently the contrary has been found to be the case; and then it is a matter of the highest importance to remove any accumulations which may have taken place, and prevent them for the future. For this purpose it is necessary to have recourse to efficient purgatives; but the less irritation we produce, the more likely we shall be to afford permanent relief. If we can obtain the effect by calomel followed by castor-oil, we cannot possibly do better; or there are some advantages in the employment of a combination of calomel and rhubarb, which may render that a more convenient form of remedy."

Dr. Bright, in the Guy's Hospital Report, says,—

"Here, again, my practice has undergone modification; for it is but in very rare instances that I use calomel as the remedy to precede the administration of the castor-oil, and I still more rarely now make use of the calomel and rhubarb. As regards purgatives in the confirmed stages of fever, I almost entirely confine myself to small doses of hydrargyrum c. cretâ, varying from two grains to five, and followed, in about four hours, or on the next morning, by a dose of castor-oil, often limited to two drachms, seldom increased to half an ounce, and never exceeding six drachms, to which I very often add from two to six drops of tincture of opium."

We quite agree with Dr. Bright that this modification is "far from unimportant;" for in the one case we are told that "we cannot possibly do better than" use calomel with castor-oil or rhubarb, where those produce the desired effect; and in the other the author informs us that he follows the practice he himself recommended "but in very rare instances."

Again, as to the means of removing the irritation which is so often set up in the mucous membrane of the great intestines, even the hydra. c. cretâ is discarded as too stimulating;—witness the early part of the case detailed above; and still more strongly what follows:—

In the *Reports of Medical Cases*—"To obviate this state," I have formerly said, "I find that the combination of the hydrargyrum c.cretâ, the ipecacuanha, and

the compound chalk powder, in different proportions, is almost always the most applicable remedy; and, in many cases, I have scarcely used any other combination throughout the disease. Under this treatment, simple as it may appear, with the mildest nourishment, I have seen the stools gradually change their character, the febrile symptoms regularly retire, and a state of complete convalescence succeed to the most threatening symptoms."

But in the *Guy's Hospital Reports*— "Now, though I have had many opportunities of knowing that this practice has been followed by others, since the above was written, with great satisfaction in the result, yet it is upon this passage chiefly that the foregoing case is intended to form a comment and a stricture. I conceive that even this mild combination is very generally too irritating for the diseased intestines; and I have had reason to think it has, in many cases, kept up the irritation, or, at all events, allowed it to continue longer than would have been the case had a still milder and more soothing practice been adopted: and, in point of fact, I have for some years very seldom had recourse to this combination, except for temporary purposes, scarcely ever now continuing its use in the way I once recommended."

Dr. Bright need not have been apprehensive that the change of his opinions would be deemed as slight; to us they appear to involve a total abandonment of a principle—we mean that of the alterative effect of mercury in cases of fever. In the former passage we are told, as the result of observation and experience, that a certain remedy "is almost always most applicable;" and in the latter, he says that he "scarcely ever" uses it as he had recommended.

The opinions of Dr. Bright deserve attention, and cannot fail to be treated with respect; but we venture to ask whether, even in the case he has given, it may not rationally be conjectured that the recovery would have been more rapid (for the patient was not declared to be "quite convalescent" till the fifth week), and the subsequent relapse avoided, if moderate doses of mild mercurials had been administered. At all events, the case is not calculated to prove any superiority in the treatment adopted; and we think, that to justify so great a change, the results of comparative trials on a very large scale ought to have been [illegible] us.

For the mild mercurial plan Dr. Bright has substituted the administration of small doses of carbonate of soda (see the case above given), a practice which he attributes to Dr. Addison, but which is really nothing else than the "saline treatment" of Dr. Stevens. Where the bowels are very irritable, clysters consisting of a few ounces of starch or gruel, with from one to three drachms of syrup of poppies instead of laudanum, are strongly recommended. Having once more expressed our opinion that Dr. Bright greatly under-rates the power of cautiously regulated mercurials over fever, we shall conclude this notice with the following summary of his present views:—

"Thus, then, were I briefly to state the few rules and remedies on which I am accustomed chiefly to depend in that class, and that stage of fevers to which the present observations refer, I should say—Keep the patient as tranquil as possible, and, on the slightest indication of cerebral affection, whether primary or secondary, let the head be shaved, and a cooling embrocation be applied. In nine cases out of ten, supposing there are no obvious bronchial or catarrhal symptoms, great comfort, and great alleviation of the general febrile state, will be the result of this measuse. Let the only food be fresh barley-water, or toast-water; or if, occasionally, a little more support be required, arrow-root, and mild animal broth. Let the soda be given regularly; and watching the condition of the bowels, regulate the evacuations with the hydrargyrum c. cretâ and the castor-oil: if the bowels need restraint, use injections of poppy-syrup and starch: if abdominal tenderness come on, apply the linseed-poultice; or apply leeches, if the tenderness be urgent. In all cases, let the condition of the bladder be frequently ascertained, by placing the hand over the lower part of the abdomen: for, more particularly when the head is much affected, the bladder is apt to become distended, owing to the unconscious or powerless state of the patient; and this aggravates greatly all the cerebral symptoms. If the strength begin obviously to fall, the infusion of serpentaria, with a few grains of the subcarbonate of ammonia, is generally the best stimulant tonic: and when wine is administered, it should be with great caution, and measured by the ounce, not trusted to the judgment of attendants."

St. Thomas's Reports. No. 1.

We should have noticed this *brochure* before, had the copy (which *of course* was sent) ever reached us: as it is, having only procured it at our publishers after the preceding had been some days on our table, we have neither time nor space left to do more than say, that it is premised, by some judicious remarks on clinical instruction given by Mr. Travers, that it is less pretending, and a more bonâ fide "Hospital Report," than its rival. We shall recur to it, if we find any thing in it likely to entertain our readers, or deserving publicity.

A Series of Botanical Tables, with four coloured Medico-Botanical Maps of Europe, Asia, Africa, and America, shewing the geographical situation of all the plants in the Pharmacopœia. By W. K. Toase, &c. London. 1835.

That a work upon the plan of that here described, if ably executed, would be a useful companion to the student, can scarcely be doubted; but however much we may feel inclined to commend Mr. Toase for the idea of his work, we cannot extend our commendations to the execution of it.

The object of the work is, however, very different from what would be conceived by a perusal of the title-page,—it is to be learnt from the colophon at the end—viz. the table of fees which Mr. Toase expects from those whom he professes to assist in their studies previous to presenting themselves for examination at Apothecaries' Hall. Now we very much fear that the four preceding tables and maps will neutralize the last, inasmuch as an inspection of them, from the incompetence they exhibit, will inspire a doubt—nay, more than a doubt—as to the competency of the author to execute the matters stated in the last. Table No. 1 consists of a Key to the Linnæan System, with a corresponding arrangement of medical plants. In this table, of 198 names of plants, there are at least 20 which are incorrectly spelt. The author seems to make no account of the practice of all botanists of spelling the second or trivial name of certain plants with a capital,—we presume from ignorance of the reason of such practice. Old exploded names are retained, in the year 1835, which have been disused for a quarter of a century, while the locality assigned to others is not the most modern; nor are the localities assigned as the place of growth of certain plants, in the maps, more happy or conformable to the knowledge of the present day. Mr. Toase is, however, entitled to the praise of originality in some cases; for he has not only ascertained that there is such a plant as that called by Linnæus *Amyris elemifera*, but also that it grows in three different parts of the world, viz. in Arabia, in Brazil, and North America. Another of his discoveries, the merit of which no one will contest with him, is that the *Quassia Simaruba* grows in North America. But enough of this abortion. We would recommend Mr. Toase to circulate his advertisement apart from the tables and maps, which would be a more honest proceeding, inasmuch as he would thus not make others pay 4*s.* for it, and it might answer the object better,—as no prudent individuals, looking at the preceding pages, will resort to him for assistance in their studies.

MEDICAL GAZETTE.

Saturday, January 9, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

Cicero.

THE HUMANE SOCIETY AND ITS EXERTIONS.

We have read with much interest the report of the Committee of the Humane Society appointed to inquire into the circumstances of the late loss of life at the Serpentine river.

We had previously noticed several points in the evidence given at the inquest which seemed to require explanation. The chief of these points were—the time which elapsed previous to drawing the bodies out of the water—and, secondly, the number of persons actually employed by the society, and on the spot at the time of the accident.

At the Serpentine, seven lives were

lost out of fifteen in a state of suspended animation. The proportion is very large, when we consider what has been done on other occasions by the officers of the society; and if the result cannot be attributed to time lost before assistance was administered, or to a deficiency of hands at the receiving-house, we can only say that in this instance the efforts of the medical men were peculiarly unsuccessful and unfortunate.

Appararent death by drowning, we are aware, is a subject attended with much mystery and difficulty. The chances of resuscitation depend upon several circumstances connected with the period and the mode of submersion, the state of the drowning person, &c., which cannot be immediately appreciated, but which always render the prognosis more or less doubtful. Some worthy old authors have handed down to us histories of recovery where the submerged had lain sixteen hours, three days, and even seven weeks, in the water. But as we believe that the age of miracles did not extend to the seventeenth century, when these *facts* are related to have happened, and as we have reason to think that human beings were not differently organized formerly from what they are at present, we must respectfully decline giving credence to the marvellous histories aforesaid. We can believe, however, that there have been some rare cases of recovery where individuals have remained above an hour in the water. In the Paris arrangements for the resuscitation of the apparently drowned, *twelve* hours are taken as the *maximum*, beyond which there is no hope. Where it is ascertained, for instance, that a person has been eleven hours submerged, no means of probable succour are left untried: and the result of this practice is highly satisfactory. We learn from the official returns made by M. Marc, that of 1849 persons apparently drowned (between the years 1821 and 1826), 576 had been submerged for less than twelve hours; and of these 430 were saved.

But still more than the time of submersion, the mode in which it has been effected, and the state of the party at the moment, influence the chances of resuscitation. If submersion be preceded, or immediately followed, by apoplexy—as in the case of people falling into the water in a state of drunkenness—the instances of recovery are extremely rare. Not so where syncope occurs, as where a person faints with terror at the instant of submersion, or immediately before; for in this state, as is known, respiration may remain suspended for a period more or less considerable; and probably the greater number of those cases, which seem most anomalous, where recovery has been effected after a sojourn of two hours or upwards in the watery element, have been of this description. There are, besides, a number of other accidents which must enter into the calculation, if we want to estimate the amount of the chances of recovery: there may be sudden palsy, concussion of the brain, a shock received at the pit of the stomach, or the like, rendering all human assistance fruitless.

Yet, when the bodies are dragged up, there is no mode of distinguishing the hopeless from the hopeful: the mere appearances, unless when putridity is present, teach us nothing as to the chances of success. Some authors, it is true, have attempted to show the contrary: but perhaps there is, after all, nothing better known than what Hippocrates himself has told us,—that it is a fatal sign when foam is observed about the mouth of the apparently dead. M. Piorry in a great measure confirms this remark of the father of physic, in his valuable memoir on respiration, in which

he says, "Where there is no froth in the air-passages, the person not having respired between the moment of submersion and that of asphyxia, the case is very different from that in which there is froth—the result of struggling and agony in the act of drowning: the hope of rendering assistance in the former case is far greater than in the latter. There is reason to believe, that where a man has been asphyxiated without being terror-struck, has made no efforts to keep himself afloat, and, in fact, has not reappeared on the surface of the water after the first plunge, such a person will more readily be resuscitated than one who has sunk under different circumstances. It is even probable that where an abundant foam is found in the mouth and air-passages, recovery is impossible."

Making every allowance, however, for the difficulties of estimating the chances of success, we are still at a loss to account for the large proportion of lives lost on Christmas day, at the Serpentine. There must have been either time lost, or there was a deficiency of proper assistance. The drummer of the Fusilier Guards, who acted with such intrepid energy on the occasion, deposed, in evidence at the inquest, that much time was lost; that ten minutes elapsed before the first boat was brought up, and probably twenty minutes, or half an hour, before the third made its appearance. It seems probable, however, that the witness did not take a correct note of the lapse of time; he was immersed up to the shoulders in freezing water, while making his observations, and it is certain that the first boat which came to the succour (for there were four) escaped him altogether, being hid by the intervening crowd. The weight of evidence, as the matter now stands, is to the effect that not many minutes were lost in dragging up the bodies; that the first body, in fact, was in a warm bath in two or three minutes after submersion, and the whole fifteen were under treatment in no very long time.

Thus, then, we are necessarily driven to the inference that there was a lack of *medical* assistance in the work of resuscitation. It must not for a moment be supposed that we mean to impute the slightest deficiency of skill to the gentlemen employed, nor, we believe, can there be pointed out the least material defect in the means and appliances of the Society, in regard to the apparatus and things needful for the recovery of persons in a state of suspended animation. But the fact is undeniable, that here were *fifteen* bodies all at once, and under one roof, to be attended to by *seven* medical men. In this view of the case, perhaps, many will rather be surprised that so many as *eight* were recovered.

The conclusion at which we arrive, after a very deliberate survey of all the circumstances, is, that the means of the Humane Society were inadequate on the occasion of the late accident. For all *ordinary* emergencies, we believe the resources of the Society to be admirable, and to leave nothing to be desired; but in such circumstances as those occurring on Christmas day last,—when there were thousands of persons on the ice, and above seventy fell in when it broke—*extraordinary* arrangements should have been adopted, in order to provide against the possible accidents. What were *eight* or *ten* men (if there were so many), to guard the banks and to be ready with ropes?—and what, as we have just now observed, what were *seven* medical men when there were *fifteen* dying persons simultaneously to be attended to?

We have no fault to find with the Humane Society: it is an institution

beyond all praise. It is a glorious example of what the British nation is capable of doing through a pure impulse of benevolence. That it is not *all*-efficient is not to be wondered at: that it exerts itself, however, to the utmost extent of its means, is beyond a question; and as its managers, therefore, very properly say, "if the public expect more from us, the public must contribute more: no expense is spared, within the limits of our funds."

This leads us to another point, of no small importance. We want to know why, or on what reasonable principle, it happens, that government lends *no* assistance to the Humane Society? Not even on an extraordinary emergency, like that which lately occurred, and when so many accidents might have been anticipated, was there the least provision made by the Home Office for the prevention of dangerous casualties. A police force, we understand, was on the spot; but however efficient that body might be in the way of catching thieves, or removing the riotous, it could be of little or no use in saving persons from drowning, much less in rendering assistance in the work of resuscitation. Why have we not, particularly on such marked occasions, a regularly organized band of *secouristes*, under the direction and control of competent officers? Why is there no annual grant of money in aid of the funds of the society? The government surely ought to do more for a national body of this sort than merely giving it a charter, and the title of Royal. How it would excite the surprise of continental states, were they to know that our Royal Humane Society, whose reputation is European, receives not one farthing from the British government in furtherance of its benevolent objects!

On what a very different footing those things are managed (we will not, however, say *better* managed, in any other respect than as regards the co-operation of government) in other countries—especially in France—may be gathered from a circumstance of no very distant date. About two years since, the French Minister of Commerce and Public Works wrote to the Prefect of Police to inquire—whether their means of rendering succour to the drowned were as complete as they ought to be, considering the advanced state of science; and whether the institutions of other countries in this respect possessed any advantage over those of France? The consequence of this inquiry was the immediate reference of the question to a commission of the Council of Health, by whom, with the assistance afforded by the Foreign Ministers and other official functionaries, a body of information has been procured, and offered to the public, in the highest degree valuable. It is not, however, the actual result on which we set such a price, but rather the principle by which the French government was actuated in setting such an investigation on foot: it shows a praise-worthy interest on the part of the governing body in behalf of the governed. And so we hold it ought to be among us; there should at least be manifested a far greater care of the subject than our official people seem disposed to entertain.

We hope, however, not to be misunderstood. Great latitude must be allowed for the difference of manners between this and other nations; and that it is the feeling in this country not to be dictated to, nor interfered with, in matters of benevolence, is a thing of common notoriety. The government know it well: but, as it strikes us, they sometimes take advantage of it rather unfairly,—in fact, to do nothing, even where imperatively called upon to lend

their assistance. That such is the case in regard to the supply of adequate succour for the apparently drowned, we have already expressed our opinion: and we repeat, that though the Humane Society is abundantly and admirably adapted for all ordinary emergencies, it is unworthy of the government of a great nation like this, not to be prepared for extraordinary occasions, which may often arise in so great a metropolis, but to be dependent, for the safety of the liege subjects of the realm, on the resources of a private Society, which is without *power* to enforce its regulations, or *funds* ample enough to render it as efficient as it ought to be.

MEANS OF SAFETY IN THE MINES.

In our last remarks on this subject, it was mentioned that the Parliamentary Committee laid the chief stress on ventilation and the use of proper safety-lamps, as the best means of preventing the occurrence of disastrous accidents. We extract the following from the Report, as it contains some observations curious both in a historical and scientific point of view. The guarded and very tender manner in which the reputation of Sir Humphry Davy is handled by the Committee, is, perhaps, on the whole, the most satisfactory, as it is certainly the safest, mode in which a matter of so much national interest can be treated. Had Davy lived, we have no doubt but such modifications would have been adopted in his lamp as would have rendered it, what all the world is convinced now that it is not, a safe and efficient instrument.

"Your Committee have endeavoured to investigate with strict impartiality the merits of the different lamps which have been brought under their notice. In the course of the evidence many varieties will be found described. The invention claimed by the late Sir H. Davy, on principles demonstrated by that able philosopher, may be considered as having essentially served the mining interests of this kingdom, and through them contributed largely to the sources of national as well as individual wealth. Many invaluable seams of coal never could have been worked without the aid of such an instrument; and its long use throughout an extensive district, with the comparatively limited number of accidents, proves its claims to be considered, *under ordinary circumstances*, a safety-lamp.

"The attention of your Committee has been drawn by different witnesses to contingencies in mining, under which the lamp of Sir H. Davy ceases to afford adequate protection. Of the possible existence and nature of those contingencies, your Committee have ascertained that the inventor was well aware, and they regret that the cautions he gave to some of his immediate friends were not made more public. Accidents have occurred where his lamp was in general and careful use; no one survived to tell the tale how these occurrences took place: conjecture supplied the want of positive knowledge most unsatisfactorily; but incidents are recorded, which prove what must follow unreasonable testing of the security of that lamp; and your Committee are constrained to believe, that ignorance and a false reliance upon its merits, in cases attended with unwarrantable risk, have led to disastrous consequences. The proofs collected in support of this opinion may be considered as so many warnings to the miners of England. The prejudices which exist in many districts against the employment of the Davy-lamp are not occasioned by doubts of its protective character: the complaints made are of too little light, and the difficulty, in comparison with the use of the common candle, in bringing that light to bear with precision on the work, particularly in the thicker seams which are found in Warwickshire, Staffordshire, and other counties. Notwithstanding these prejudices, your Committee conceive that no employer of miners can be justified in allowing caprice, or inconvenience to certain individuals, to interfere with a due protection to the lives of his workpeople. In some mines, now lighted by the ordinary means, the use of the lamp ought, in the judgment of your Committee, to be compelled by the owners.

"Many improvements, calculated to lessen the number of dangerous contingencies already alluded to, have been suggested; all these may be considered as extensions of the principle: such are the lamps produced by Messrs. Upton and Roberts, Mr. Newman, Mr. Martin, Mr. Douglas, Mr. Wood, and Mr. Dillon. The lamps of Dr. Clanny and Mr. Ayres are provided with additional mechanical contrivances, intended to exclude danger which might overcome the safety principle, and at once warn the miner of the in-

security of his situation by the extinction of his light.

"In the experiments made before your Committee at the London University*, it may possibly be remarked, that the tests applied were not such, in nature or mode of application, as the known actual condition of the mines would point out as satisfactory. It must not be forgotten that the object of those experiments was to ascertain which of all the lamps produced was, when exposed to the severest trial, best entitled to the name of a safety lamp. In these experiments the explosion of the gases within the lamp was effected in every one, and similar explosions produced externally, save Messrs. Upton and Roberts's. Your Committee are therefore decidedly convinced that its construction possesses paramount merit.

"Your Committee cannot admit that these experiments had any tendency to detract from the character of Sir H. Davy, or to disparage the fair value placed by himself upon his invention. The improvements are probably those which longer life and additional facts would have induced him to contemplate as desirable; and of which, had he not been the inventor, he might have become the patron.

"With the sole exception of unexpected destruction of the instrument, Messrs. Upton and Roberts's lamp appears to your Committee to provide against all, or nearly all, the contingencies attending the Davy-lamp. Mr. Buddle states that tin shields, and a partial concealment of the lamp under their dress, constitute the prudential precautions taken by the miners in dangerous situations, to prevent the flame passing the gauze when the lamp is agitated. The glass chamber does all this with greater certainty; its sudden fracture leaves the instrument a perfect lamp on Sir H. Davy's construction. The introduction of the glass is not new; the novelties are, the shape of the glass, the collar which regulates the admission of air or gas to the cotton wick, and the double tissue of gauze beneath the wick, which prevents firing backward. If no practical objections are discovered, and your Committee do not contemplate any which may not be readily overcome, Messrs. Upton and Roberts's lamp will supply a grand desideratum, especially if extensive experience should prove that the lamp and area of the gauze may be so increased as to allow of more light with safety."—*Report: Accidents in Mines.*

LECTURES

ON THE

DISEASES OF THE NERVOUS SYSTEM.

BY M. ANDRAL.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

INFLAMMATION OF THE SPINAL MARROW.

The subject of Myelitis continued—Anemia of the Nervous Centres—Anatomical Characters—Symptoms—Treatment — Hæmorrhage of the Nervous Centres—State of the parts in and around the effusion—General state of the Brain—State of the Cerebral Membranes—Causes—Influence of Sex and Age—Affections of motion—Paralysis resulting from Hæmorrhage of the Cerebral Hemispheres.

Myelitis continued.—In the *Bulletin de la Société Anatomique* is related the case of a female who became paraplegic and died. It was supposed that the symptoms had indicated myelitis, but, on post-mortem examination, nothing whatever to justify this idea was found about the spine. The only morbid phenomenon was that all the bones were extremely brittle, and it was satisfactorily ascertained that the appearance of paraplegia might have resulted merely from the destruction of the head and neck of both femurs, which had taken place in such manner as to interfere with their movements.

Of late years an attempt has been made to generalize certain facts, and various writers, first in England, and afterwards in Germany, have described a peculiar condition, the seat of which is laid in the vertebral cord, under the name of spinal irritation, and which is supposed to display itself by producing disease in parts of the system more or less distant. The name of "Spinal Irritation" was proposed by Mr. Griffin, and adopted by M. Ems, who has also published on the subject. According to these authors, this condition of the spinal cord is not inflammation, but, as the name implies, an irritation, *sui generis*, which leaves no appreciable change of structure. According to these views, every part of the body is in relation or connexion with some portion of the vertebral cord, and pressure at this point would act upon the part connected with it so as to produce pain; and therefore, in order to establish their diagnosis, these gentlemen follow a course different from that usually adopted. Let a patient have cough, or palpitations, or gastritis—in fact, any thing—they begin by examining the spinal column, by applying pressure to

it with the hand, and they assert that when they arrive at the spinous process of a particular vertebra, pain is instantly felt in the part which is the seat of the diseased manifestation— in the epigastrium for instance, if it be the stomach which is deranged. It is required, in order to detect a disease by pressure on the vertebræ, that such part should receive its nerves from the spinal cord; they hold that many cases of headache originate in this same spinal irritation, and that various forms of deafness, amaurosis, morbid affections of the sense of smell, and even mental hallucinations, are attributable to the same cause; they even pretend that in some persons affected with blindness, pressure on the spinal column causes pain of the eye. The same observations apply to the chest, many of the diseased conditions of which are attributed to the spinal marrow; which, however, is much more feasible than the former. Neuralgia of the heart is regarded by those authors as usually deriving its origin from the spine, as well as certain painful conditions of the integuments over the sternum. Nevertheless, it is but the other day that a man presented himself to me, having an acute pain in this situation, and which was aggravated by touching the sternum or ribs. This patient had also habitual dyspnœa, but he was in other respects in good health, and had no lesion of the heart or lungs. I was not able, however, to obtain any of the results promised by these authors, whose opinions I am now submitting to scrutiny, and the whole theory may be regarded as an extension of certain well-known facts from which they have generalized prematurely and fallaciously.

Myelitis sometimes lasts but a few days, while in other instances it may endure for several years, and I have known so many as ten elapse between the supervention of the symptoms, and their fatal termination.

Myelitis may be cured, but the prognosis ought always to be guarded. The disease often proves fatal, and it may do so in various ways, viz. 1. By extending to the brain. 2. By the lesion of respiration. 3. By lesion of the heart's action. 4. The brain, respiration, and heart, remaining undisturbed, the patient may become gradually weaker, and lose each day something of the power which resists the disease; or sloughs may form, and life be slowly extinguished without any important functions being greatly affected.

The *treatment* is to be conducted on principles essentially the same as that of encephalitis. Leeches are to be applied in the form of a line along the whole course of the spine; cupping is also required. If the inflammation be chronic the leeches must not be laid aside, but revulsives are to be more particularly employed. *Douches* of different kinds have been recommended, such as the waters of Plombieres. Derivation to the intestinal canal by means of purgatives, is also to be practised.

ANEMIA OF THE NERVOUS CENTRES.

This disease is remarkable, inasmuch as it presents more than one trait in common with the symptoms of hyperemia, and yet it is very important to establish the diagnosis between the two affections, inasmuch as they require diametrically opposite methods of treatment.

The anatomical characters consist in discolouration of the nervous pulp, particularly the grey, which appears no longer to contain the vessels which are apparent in its natural state; its aspect approaches to that of the white substance; one would suppose it had undergone an actual maceration. Sometimes the anemia is attended with induration, sometimes with softening. It may be associated with a state of general anemia, in consequence of violent hæmorrhage, or it may succeed to chronic diseases, which have produced an impoverishment of the blood. It is not uncommon to meet with it after acute diseases, such as certain forms of gastro-enteritis, particularly in children. Sometimes it comes on without having been preceded by any disease which could have had an impoverishing effect upon the blood, but exists alone and independently of any other affection. If an animal be copiously bled, so as to produce death from hæmorrhage, we observe that in proportion as the brain becomes deprived of blood, convulsions supervene, and this symptom has also been met with in men dying from loss of blood. It may be established as a general principle, that the too great diminution of blood in the organs of the body is productive of disorder as well as is the opposite condition; with too little blood digestion is badly performed, or not performed at all, and palpitations occur in chlorotic patients as well as in those affected with hypertrophy of the heart.

Symptoms.—With regard to the intellect, delirium has been observed in a certain number of cases. M. Papavoine has published some cases in which children were rapidly carried off by an acute disease amidst violent delirium; on examination after death, the brain was found to be remarkably pale. This delirium is analogous to what arises from too spare a diet, particularly in infants and nervous persons. The same effect is produced if the brain be deprived of stimulants to which it has been accustomed. An individual addicted to the use of spirituous liquors, is put in prison, and there fed on bread

and water; he falls into a state of extreme weakness, becomes pallid, and has the nervous system deranged; he experiences insomnolence, disturbance of intellect, and some degree of delirium. So far from regarding these symptoms as dependent on congestion of the brain, the medical attendant restores to his patient his brandy and his former diet, and this has no sooner been done than his equilibrium returns, and the delirium disappears. A German physician named Osbund, has made some observations strongly corroborative of this.

With regard to motion, there may be convulsions, or various other disturbances.

The sensibility is increased in a very remarkable manner. Blisters or sinapisms applied to the skin, produce intolerable pain, and hence the precept not to have recourse to cutaneous stimulants in individuals who have been too copiously bled; in the same manner as it is imprudent to employ them when violent re-action is still present.

Treatment.—If by investigating the previous history and habits of the patient, we come to the conclusion that the symptoms are dependent on a state of anemia, the treatment must be founded on this circumstance. In patients arrived at a very advanced stage of typhus fever, in whom all that remains is nervous depression, the inflammatory symptoms having now disappeared, the further abstraction of blood could only be productive of evil, and the equilibrium becomes restored in proportion as aliment, and consequently strength, is cautiously supplied.

HÆMORRHAGE OF THE NERVOUS CENTRES.

Hæmorrhage of the nervous centres has long been known under the name of apoplexy; but this denomination cannot in the present state of science be regarded as synonymous with hæmorrhage; for, on the one hand, the symptoms of apoplexy may occur without there being any hæmorrhage, as in certain kinds of softening; and on the other hand, hæmorrhage may take place without the phenomena which characterize the apoplexy of nosologists. In a word, apoplexy is a term representing certain symptoms connected with very different conditions of the organ.

Hæmorrhage may have its seat in almost any part of the nervous centres. We see it most frequently in the hemispheres of the brain, and the part of those hemispheres where it is most common is that which is situated externally to, and on a level with, the optic thalami and corpora striata; it is also common in the two great ganglions themselves. The corpora striata and optic thalami may alone be implicated, but this is less common than it is to have the cerebral mass which surrounds them also affected. It may also happen that the disorder is seated just externally to these bodies, and leaving them intact. We also meet with hæmorrhage in the centrum ovale, and neighbouring points of the brain; in the anterior, middle, and posterior lobes. Sometimes, again, the convolutions only suffer, the rest of the cerebral substance remaining quite healthy.

Such are the different parts of the hemispheres of the brain where hæmorrhage has been observed; but there are other points of the encephalon into which blood may be effused. Thus, examples have been met with in the mesocephalon, or the prolongations which run from the protuberance to the hemispheres of the brain and cerebellum has been the seat of the extravasation.

The cerebellum is much less frequently affected with hæmorrhage than the brain, but this is occasionally seen either in the lateral lobes of the organ, or in that portion which has been called the median lobe.

The spinal marrow may be the seat of hæmorrhage at any point from its origin to its termination.

Sometimes the effusion takes place into the ventricles themselves, although much more frequently the blood which may be found in them comes from a laceration of the nervous substance surrounding them. M. Montault has related a case of hæmorrhage into the fourth ventricle. The septum lucidum may be ruptured, and an effusion which has taken place originally into the lateral ventricle of one side may pass into the other.

Hæmorrhage may take place into the membranes themselves, and it is to this form that M. Serres has given the name of *apoplexie meningée.* It is an extremely rare disease, and frequently, by a more careful examination of the brain, blood is found in its substance, which has made its way through the membranes by a kind of transudation. As to size, the hæmorrhagic effusions into the brain are sometimes very small, scarcely exceeding that of a pin's head, while at others they may give rise to one vast cavern occupying the hemispheres. With regard to their number, there may be but one point of hæmorrhage, or the brain may appear as it were riddled by an immense number of such deposits, either of the same date, which, however, is rare, or produced at periods more or less distant from each other, which is much more common than the former. Some effusions appear to take place only consecutively of others; thus, hæmorrhage into the cerebellum is rarely seen without the same affection of the brain, which renders the symptoms of apo-

plexy of the cerebellum obscure and difficult to recognize.

The colour of the blood is the same as that of hæmorrhagic effusions in other parts of the body; at first it is liquid, but afterwards acquires the appearance of jelly; finally it takes an almost solid consistence, and remains in this condition as long as it resists the absorbents.

There are two principal sources whence the blood is derived. 1. It is furnished by an exhalation from the capillaries, without the laceration of any considerable vessel; or 2, it comes from a vessel of appreciable size, the rupture of which has produced the hæmorrhage. The blood once effused, may increase in quantity, by continuing to flow from the same source which originally furnished it. The effusion may continue the same, or it may be reabsorbed; a very remarkable operation, which the physician may perhaps favour, but which he cannot excite. Complete reabsorption of the blood which has been effused leads to a radical cure of the diseases: a cyst is produced; the blood is surrounded by a cellular membrane, the internal surface of which exhales a serous fluid; this becomes mixed with the blood, divides it into numerous grumous portions, and thus facilitates its absorption. At length there arrives a time when the blood having entirely disappeared, or nearly so, there remains nothing in the cyst except a little serum, and cellular bridles running from one side of it to the other.

The blood being absorbed, the work of nature does not terminate here, and now an effort is made to effect the disappearance of the cyst; this has a tendency to become effaced, and having served its purpose, it leaves in its place only a linear cicatrix. All the stages of this reorganization may be traced, and it is particularly to modern writers that we are indebted for the most precise observations on this subject, among whom we may mention the names of M. M. Riobé, Rochoux, Cruveilhier, &c.; but we find in Bonnetus, Wepfer, and Morgagni, certain passages which clearly show that they had been aware of the process of cicatrisation of the cerebral tissue: witness the following explicit phrase:—" *Connivebat cavernula et jam coalescebant inter se parietes.*"

M. Foville has pointed out two modes in which cerebral hæmorrhage may take place. The labours of some anatomists, as you know, have led to the belief that the medullary matter may be unfolded in such manner as to show that it is formed of superimposed plates. M. Foville, taking this as a starting point, says that hæmorrhage may take place, 1st, in the midst of lacerated brain; 2d, into the interstice, between the cerebral plates above-mentioned, effecting their separation.

We have here to consider a difficult and interesting question. When the nervous pulp is destroyed can it be reproduced, or is the cicatrization constituted solely by the intervention of cellular texture, without the formation of cerebral matter? M. Serres thinks that in certain cases the nervous pulp is susceptible of a complete regeneration. The cicatrization takes a longer or a shorter time to be accomplished: thus, in some persons, a simple linear cicatrix alone is found within six months after the apoplectic seizure, whilst in others the cyst remains entire many years after the attack. In this case the process of cicatrization has been arrested. As to the state of the vessels immediately around the effusion, they may present no appreciable breach of their continuity, nor any other change, but they may also be the seat of various lesions, which act an important part in the production of hæmorrhage; such as ossifications, cartilaginous deposits, remarkable friability, &c.; or we may even find some vessel ruptured within the cavity containing the coagulum, or at some distance from it. M. Michelin has related a case of hæmorrhage into the optic thalamus, wherein a vessel running to join the choroid artery at the base of the skull was ruptured within the apoplectic cavity, the orifice being plugged up by a clot. The hæmorrhage is sometimes owing to rupture of the basilar artery, or the branches connected with it, and indeed there is no artery carrying red blood on the external surface of the brain, the influence of which may not be productive of hæmorrhage.

State of the parts in and around the effusion.—The nervous pulp may present various alterations surrounding or in the centre of the apoplectic effusion. Within the nucleus the cerebral substance may be wanting, or if present may be altered and softened; while in the midst of this softened tissue are found the cellular bands of which we have spoken. Is this softening preceded or followed by the hæmorrhage? Sometimes the softening has evidently preceded the effusion, as we find only some very small coagula in one vast mass of softening; and in certain cases hæmorrhage may be the means of breaking down the cerebral substance before it, this being merely a mechanical effect of blood being poured out in an organ having little power of resistance.

There are cases where close to the nucleus and within a fraction of a line from the point of hæmorrhage, the brain regains its natural state. Sometimes it remains injected, and more or less deeply coloured; in other cases it presents the appearance

of simple imbibition, without genuine injection of vessels; or the nervous tissue around shows an appearance of ecchymosis, and we may then have the different shades of colour peculiar to that state. Under more than one circumstance the softening may precede the effusion, as M. Lallemand has abundantly proved. It may also happen as a secondary consequence, either a very short time after the hæmorrhage, or not until a very remote period. If the effusion be old, we may find the nervous substance round the nucleus either healthy or variously discoloured, softened or indurated.

General state of the brain.—Great congestion is often observed, and a knowledge of this fact is important, because frequently the symptoms depend less upon the apoplexy itself than upon the cerebral congestion. In the process which follows the hæmorrhage, changes may arise which do not depend in any degree upon the extravasation, but upon the hyperemia. If the hæmorrhage be considerable, it may happen that the hemisphere which is the seat of the extravasation is not the only one to suffer, whether this arise from congestion of the general mass, or from the bursting of the blood from one ventricle into the other by the rupture of the septum lucidum; a circumstance which may act a more or less important part in the production of some of the symptoms which accompany apoplexy.

State of the cerebral membranes.—These may be completely healthy, or show appearances of congestion, or of an infiltration of blood. When the hæmorrhage has taken place long before, and a sanguineous nucleus remains, the membranes of the surface as well as of the ventricles may be filled with serosity, and in some cases individuals in their progress of recovery from the hæmorrhage have been carried off by these serous infiltrations of the meninges, or into the ventricles, the cause of death being, in fact, genuine chronic hydrocephalus. It thus appears, that in the disease of which we speak, we must keep in mind not only the hæmorrhage, but all the above circumstances which may be complicated with it.

Causes.—There is little to be said on this subject; the causes which produce congestion are the same, which being present in a more intense degree, or occurring in individuals otherwise predisposed, give rise to hæmorrhage; there are, however, some remarks relative to the etiology of this affection, which it may be proper to make. From certain investigations instituted with a view of determining the influence of different temperatures, it has been ascertained that at Paris, attacks of true cerebral hæmorrhage are more common during the winter than the other seasons. In a calculation founded upon 177 cases, I have arrived at a similar result; thus there were,

During Winter	60	Cases.
——— Spring	42	do.
——— Autumn	40	do.
——— Summer	35	do.

It has been inquired whether apoplexies have been equally frequent at different periods, and it would appear from the register compiled in London by Heberden, as quoted by Bateman, that from the beginning to the end of the eighteenth century, the number of cases of apoplexy had obverved an increasing progression. M. Falret instituted a statistical investigation into the number of cases of apoplexy which occurred between January the 1st, 1794, and December the 31st, 1823. The number proved to be 2297. The above thirty years, divided into three periods of ten years each, give the following proportions: first period, from January, 1794, to December, 1803, only 399 cases; second period, from January, 1804, to December, 1813, 979 cases (that is to say, nearly three times more than the first period) from January, 1814, to December, 1823, 919 cases, being rather less than the preceding period.

As to the causes derived from the abuse of spirituous liquors, and of too stimulating food, I have only to repeat what I have already said in speaking of congestion. Apoplexies have also been known to occur as the immediate consequence of violent mental emotion, or great bodily pain; as for instance, during the operation of lithotomy. Let me remark, however, that these moral perturbations and exquisite sufferings more frequently give rise to simple congestion than genuine apoplexy.

With regard to the digestive system, there must exist a predisposition, in order to enable its derangements to act any part in the production of apoplexy.

The influence which the different conditions of the apparatus of circulation have on the production of cerebral hæmorrhage is the same as with respect to congestion. Some authors, indeed, have endeavoured to make out that a considerable narrowing of the aorta beneath its arch had a great influence in the production of apoplexy. In order to decide this question, let us take certain cases in which there has been not only narrowing, but almost complete obliteration of this vessel. Now, of four such cases, in one only (published by M. Raynaud) did symptoms referable to the brain occur. This took place in a man 92 years of age, in whom there was hemiplegia of the right side, of very long

standing. On opening the body, numerous apoplectic cells were found. The patient had the head habitually hot, and with a sense of weight; the pulsations of the temporal artery were remarkably strong. On the other hand, nearly complete obliteration of both carotids has been known to accompany the occurrence of apoplexy, although the blood could only reach the brain through the vertebral arteries. This case, related by M. Cruveilhier, neutralizes that of M. Raynaud. We must not judge from an isolated fact, but carefully avoid precipitate and premature conclusions.

The venous circulation exercises the same influence in apoplexy as in congestion; only that an embarrassment of this portion of the circulation produces the former much less frequently than the latter; one does not easily produce apoplexy by holding the head down. It has been attempted to produce hæmorrhage into the brain in animals by ligatures which prevented the blood from returning to the heart through the veins, but this has not always been easily accomplished.

Plethora and the sanguineous temperament predispose to apoplexy, but less conspicuously than to hyperemia. As to the rest, apoplexy may take place in very opposite conditions of the system. Thus, cases have been met with in which persons became apoplectic just after the loss of a large quantity of blood. The thesis of M. Portal contains instances of this nature.

Influence of age and sex.—The particular kind of plethora of pregnant women has been adverted to, and cases of apoplexy quoted as having occurred during gestation and parturition; I regard these, however, as mere coincidences; and hold that we can scarcely enumerate pregnancy or labour amongst the causes of the disease. Apoplexy has been seen to occur in women some time after their confinement, but the cases of this kind given by M. Leloutre were certainly quite accidental.

With regard to the relative frequency of apoplexy in the two sexes, Joseph Frank says, "*Inter decem apoplecticos unam enumerare soleo fœminam*;" but this cannot be admitted, for it is obviously an exaggeration. Peter Frank found that, of 1241 patients who died of apoplexy at the Hospital of Vienna, between 1787 and 1804, there were 637 men and 604 women. M. Falret, however, has arrived, as the result of his researches, at a conclusion which comes nearer to that of Joseph Frank, having found 1670 men and only 627 women in 2297 cases of the disease.

As to the question of age, M. Falret, calculating from the number above mentioned, found that the period most obnoxious to apoplexy is that between 55 and 65 years, then between 45 and 55, and then between 35 and 45; while, in other periods of life, the disease becomes more and more uncommon; a result in keeping with the aphorism of Hippocrates, in which he points out the diseases most frequent in advanced life. (Aphor. 31, sect. iii.) M. Rohoux, on a calculation of 69 cases, has found,—

From	20 to 30,	2	cases.
—	30 to 40,	10	—
—	40 to 50,	7	—
—	50 to 60,	13	—
—	60 to 70,	24	—
—	70 to 80,	12	—
—	80 to 90,	1	—

The result to be deduced from these calculations is, that apoplexy is at its maximum of frequency during a period of fifteen years, commencing at 55, and finishing at 70. Thus, above 70 years of age the tendency to cerebral hæmorrhage diminishes; and it is also rare before 30: there are examples of it, nevertheless, between 10 and 15, and even between 5 and 10. And what is remarkable, one of the rarest forms of apoplexy, that affecting the cerebellum, has been seen in an infant seven years old. Some cases of apoplexy in patients from 5 years to 1, have been published by MM. Durnet and Tonellé. M. Serres has observed one case in an infant only three months old; and M. Billard saw another very shortly after birth.

The symptoms, to facilitate their study, must be divided into several series:—1st. Some depend upon lesions which may precede the hæmorrhage, such as a congestion, the symptoms of which are altogether independent of actual extravasation. It is to these that the names of precursory symptoms, hæmorrhagic effort, or *molimen hæmorrhagicum*, have been given. These symptoms may be entirely absent. 2d. Others depend upon the sanguineous effusion itself, whether it have acted by compressing or lacerating the cerebral substance. 3d. In another series of symptoms are ranged the phenomena which the alterations coincident with the effusion (such as softening, inflammation, or hyperemia of the brain) may have produced. 4th. We have those symptoms which became developed at a longer time after the occurrence of the hæmorrhage, as encephalitis, consecutive softening, &c. It will be perceived, however, from the above enumeration of these four series of symptoms, that many of them are not constituted by the disease itself.

Before we enter into a detail of the phenomena by which the disease of which we speak is announced, there is one ques-

tion to be asked: is there any external manifestation of such occurrence every time that an extravasation of blood takes place into the nervous centres? We must answer in the affirmative as so a great majority of cases; nevertheless there are examples on record, wherein considerable hæmorrhages into the brain have been unaccompanied by any appreciable symptom. M. Lenormand has related (Journal Hebdomadaire, tom. i. p. 435) the history of a woman, 30 years of age, who suffered under a hæmorrhagic diathesis: she frequently lost blood by the mouth, nose, and intestines; she had numerous hæmorrhages from the skin, which was covered with ecchymoses; and she had that pale yellowish complexion which announces excessive loss of blood. This woman died, and, on examination, the mucous membranes were found spotted by ecchymoses; besides which, there was an enormous effusion in both hemispheres of the brain. There had been considerable debility, but none of those symptoms which usually accompany even slight hæmorrhage on the brain. This case, and another which I shall mention by and by, ought to be kept in mind, in order to be associated with other analogous facts, should such present themselves.

Let us now examine the symptoms of hæmorrhage of the nervous centres, commencing with those which result from disturbances of the functions of relation.

Affections of motion.—There is one lesion of the motive functions, which, when it supervenes suddenly and remains persistent, is perfectly characteristic of hæmorrhage of the brain: this is paralysis; but, as I have just said, it is not sufficient that it should merely show itself, nor even that it should do this suddenly; it is further necessary that it should be persistent. This diminution of muscular power exists in different degrees, in almost every case, but not actually in all. We have seen the case of M. Lenormand, above-mentioned; and in another, published by M. Suretin, in 1829, he describes a patient who died without having had any paralysis; on opening the body, a clot, as large as a hen's egg, was found at the posterior part of the right cerebral hemisphere, having implicated the extremity of the corpus striatum. This case, and that of M. Lenormand, are almost the only examples of this nature which have been recorded.

Does paralysis, when once produced, always remain alike? It appears, from many facts, that paralysis may cease for a time and then return; which circumstance may be attributed to a kind of remission in the action of the effused blood upon the cerebral mass. With the exception of such cases, which, although not very uncommon, are to be regarded as exceptions, paralysis, as a general rule, only ceases with the reabsorption of the blood.

As to the period at which the paralysis makes its appearance, this coincides with the time when the blood is effused; it becomes increased, and suddenly acquires a great degree of intensity if a second attack of hæmorrhage be added to the first. The after course of the paralytic affection may be divided into four stages—first, that of its increase; second, that in which it is stationary; thirdly, that of alternate increase and diminution; fourthly, that of constant and gradual diminution.

The intensity of the paralysis differs. In some individuals we see but a slight numbness, with a diminution, though but inconsiderable, of muscular power. They grasp less firmly; so that if they have a cane or other object in the hand, they may perhaps let it fall: this is the slightest degree of paralysis. In a more marked degree, the movements are performed with greater difficulty, till at length comes entire loss of all power of motion. It may be that this diminution of muscular contraction has not been preceded by any other accident; and under such circumstances it marks the onset of the disease. Or there may have been some muscular weakness, arising not from hæmorrhage, but from a certain degree of congestion. Some disorders of the motive powers, such as convulsions or spasm, are occasionally met with, not depending upon the hæmorrhage, but upon the lesion which has preceded it.

This paralysis, so variable in degree, by which apoplexy is characterized, presents itself in different situations, corresponding to the situation where the effusion of blood takes place. I shall consider in this point of view the hæmorrhages of, 1st, the cerebral hemisphere; 2d, the mesocephalon; 3d, of the cerebellum; 4th, the different parts of the spinal marrow.

Paralysis resulting from hæmorrhage of the cerebral hemispheres.—This may be general or partial. It is general when it occupies both sides of the body at once. I speak here only of paralysis of the limbs, intending to advert afterwards to that of other parts.

Hæmorrhage of the hemispheres produces general paralysis, under the three following circumstances:—1st, when each hemisphere is the seat of effusion; 2dly, when the hæmorrhage, although but on one side, has been very considerable, and the irruption of blood has been sufficiently violent to destroy the substance as far as the corresponding ventricle, and to penetrate this, lacerating the septum lucidum, and producing strong compression of the

other hemisphere; 3dly, when the hæmorrhage, limited to one hemisphere, and not effecting an irruption into the opposite side, is yet sufficient to compress the other hemisphere of the brain, while perhaps there may be at the same time some congestion, which assists the generalization of the paralysis. In this state the four limbs, on being lifted up, fall down again quite inert. This paralysis may persist till death, or else, having been general at the commencement, it may at a later period become transformed into simple hemiplegia: this is met with, and is even very common, in the third form of hæmorrhage which I have pointed out. Paralysis of both sides at once indicates hæmorrhage much less certainly than hemiplegia does; the former is most frequently dependent on simple congestion. Paralysis of one side only constitutes hemiplegia; and this, when it comes on suddenly, and remains persistent, shows the existence of cerebral hæmorrhage. This point must be insisted on, because it is fundamental. When hemiplegia exists, it is most common for both limbs of the affected side to be paralyzed; but, nevertheless, it sometimes happens that only one is implicated. When both limbs are seized, it is very common to have at the same time palsy of the corresponding side of the face; and the antagonist action of the muscles of the affected side being destroyed, their opponents pull the mouth to the side which is not paralyzed. But although it be a law that the hemiplegia as well as the paralysis of the face takes place on the side opposite to the hæmorrhage, yet there is an exception as regards the tongue, of which I shall speak more particularly in the sequel.

It has been attempted to ascertain the cause of the paralysis and the effusion existing on opposite sides; and it has been attributed to the interlacing of the fibres at the upper part of the spinal cord. This explanation, which appears a very natural one, has been generally admitted; we must observe, however, that at the same time that the limbs of one side are paralyzed, the corresponding side of the face in many cases is similarly affected. Now the seventh pair, which gives movement to the face, becomes detached from the spinal marrow above this interlacing; and hitherto no fibres of this nerve have been traced beneath it. This fact is a great blow to the theory. However it may be, the general law as to the paralysis of apoplexy being on the opposite side from the effusion, must be regarded as established; remarking, however, that the explanation of this is yet to be discovered.

But there are various perplexing cases, which I shall mention, and which appear contradictory of this law. There are 14 cases which have been published, and 2 others which have not, making in all 16, in which the paralysis took place on the same side as the cerebral lesion. Let us rapidly examine those cases which are of unquestionable accuracy, and separate them from those which, being deficient in the necessary details, may perhaps be referred to the general law.

The first is very old, and is to be found in the work of Bonnetus. It relates to an individual who received a blow on the left temple, and was seized with paralysis of the right side; on examination after death, effusion was found on the right hemisphere. This case is certainly not of much value, for there had been external violence applied directly to the left side of the head, being that opposite to the hemiplegia. The second is more important, and is due to Forestus, whose observations are too little read. In this, softening was found in the right hemisphere of a child, and there had been hemiplegia of the right side. At the time when this case occurred, attention had already been directed to the law of *crossing* observed by paralysis; and Forestus takes good care to remark that he looked very attentively for some change on the opposite side, but could find no trace of any such; and let me remark, in passing, that the existence of *softening* was not altogether unknown to Forestus, since in this very case it is of "softening" that he speaks. Let me remark, also, that in the examples I am about to quote of direct paralysis, I shall not only speak of the hæmorrhages with which it has been coincident, but I shall include in my analysis all the cases with which I am acquainted wherein any anatomical change of the brain has produced paralysis of the same side of the body.

EFFECT OF MARRIAGE ON THE DURATION OF LIFE.

Some very curious facts on this subject are stated by Dr. Casper, in a paper of his lately published at Berlin. It had been long ago vaguely asserted that bachelors were less long-lived than married men. Hufeland and Deparcieux were of this opinion; and Voltaire observed that there were more suicides among those who had not given hostages to fortune than among those who had. Odier, however, was the first who set on foot the inquiry with exactitude, and he found (*Bibl. Britannique*, 1814) that, in the case of females, the mean duration of life, for the married woman of 25, was above 36 years; while, for the unmarried, it was but $30\frac{1}{2}$. At 30 there was a difference of four years in

favour of the married; and at 35, two years; and so on. It may be said, perhaps, that married females ought to be considered as *picked* lives; but, as Dr. Casper observes, this is far from being generally the case, especially in the middle and upper classes of society: it is chiefly among the lower orders, where a livelihood is procured by labour, that importance is attached to the bodily health and vigour of the female. With regard to men, we gather from Deparcieux's and the Amsterdam tables, that the mortality of those from 30 to 45 years of age is 27 per cent. for the unmarried, while it is but 18 for the married; and that for the 41 bachelors who attain the age of 40, there are 78 married men. The difference becomes still more striking as age advances: at the age of 60, there are but 22 unmarried men alive for 48 married; at 70, eleven bachelors for twenty-seven married men; and at 80, for the three bachelors who may chance to be alive, there are nine benedicks. The same proportion very nearly holds good with respect to the female sex: seventy-two married women, for example, attain the age of 45, while only fifty-two unmarried reach the same term of life. M. Casper, in conclusion, considers the point as now incontestibly settled, that, in both sexes, marriage is conducive to longevity.

NOTE FROM DR. MACLEOD.

To the Editor of the Medical Gazette.

Sir,

I request that the following error of the press, in my letter to you last week, may be corrected. In reference to the reports of the proceedings of the Phrenological Society, instead of "are furnished by a common reporter," read "are *not* furnished by a common reporter."

Your obedient servant,
R. Macleod, M.D.

Henrietta St., Cavendish-Sq.

NOTICE.

We cannot give insertion to the long rejoinder of Mr. F. Winslow to Mr. Munk. Any brief explanation we might have found room for, but not for a letter containing nothing important—except, perhaps, where the writer states in strong terms that he had no intention whatever to treat with disrespect those physicians whose characters he is charged with having attempted to asperse.

SATURDAY, JANUARY 16, 1836.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XVI.

I PROPOSE in this lecture to examine our common blistering beetle (the *Cantharis vesicatoria*), the only coleopterous insect employed in medicine in this country.

COLEOPTERA.

The order *Coleoptera* has derived its name from κολεαs, a *sheath* or *scabbard*, and πτερον, a *wing*, because, when the insect is not flying, the posterior is covered and protected by the anterior pair of wings, which are horny, and constitute what are termed *elytra*, or wing-cases. The animals of this order undergo complete metamorphoses, and have a masticating mouth, or at least visible mandibles and palpi.

Divisions.—Latreille divides this order into four sections, according to the number of the joints of the tarsi.

Sect. 1. *Pentamera* has five joints to all the tarsi.

Sect. 2. *Heteromera* has five joints to the four first tarsi, and at least one to the two last.

Sect. 3. *Tetramera* has four joints to all the tarsi.

Sect. 4. *Trimera* has three joints to the tarsi.

The only one of these interesting to us pharmacologically, is the second (*Heteromera*), which includes four families, namely, *Melasomata*, *Taxicornia*, *Stenelytra*, and *Trachelidia*. The last contains those animals in which the head is connected to the thorax by a kind of neck, and includes six tribes, one of which is called the *Cantharidia* or *Vesicantia*, embracing those insects commonly employed for the purpose of blistering.

Cantharis vesicatoria.

History.—It is difficult to determine at how early a period this animal was known or first used in medicine. It is, indeed, true that Hippocrates employed an insect which he calls κανθαρις, and that the effects which he, as well as other old writers, attributed to it, are such as we know our cantharis produces. But we must bear in mind that many coleopterous insects operate in a similar manner, and that the word κανθαρις merely signifies *a small beetle*, and would be equivalent to the Latin, *Scarabæus parvus*. Dioscorides speaks of several kinds of cantharides, but says the most powerful have transverse yellow lines on the wings, while those which are of one colour are weak and inert. Pliny makes use of the very same words. So that it is tolerably clear neither Dioscorides nor Pliny were acquainted with our cantharides.

The insect used for blistering in China, and some parts of Hindostan, agrees precisely with the characters mentioned by these old writers. It is called the *Mylabris cichorei*: in these specimens [showing some] you will observe on the elytra the transverse yellow lines or bands alluded to by Dioscorides and Pliny.

Synonymes and etymology.—It is to be regretted that entomologists are not agreed as to the zoological name of the Spanish fly: by Linnæus it is termed *Meloe vesicatorius*; by Fabricius, *Lytta vesicatoria*; by Geoffroy, *Cantharis vesicatoria*.

Several insects evolve a yellowish liquor (like honey), which is acrid, and even vesicating; and hence the term *Meloe* has been derived from μελι, *honey*. The word *Lytta* probably has reference to the supposed specific power of these animals to cure hy-

drophobia. I have already mentioned that *Cantharis* is derived from the Greek κανθαρις, a diminutive of κανθαρος, *a beetle*. As they were formerly brought to this country from Spain, they are commonly termed Spanish flies; it would, however, be better to call them *green blistering beetles*.

External characters.—As the animal undergoes perfect metamorphoses, I shall examine it in its different forms, beginning with—

1. The *ovum*, or egg.—This is of a sulphur yellow colour, of a cylindrical form, and slightly curved. In about three or four weeks the larva is developed, and lies almost straight in the shell, the two layers of which are sufficiently transparent to allow the dark parts of the animal to be seen through them.

2. The *larva* comes out of the shell, according to Brandt, with the hind part of the body first. It is of a citron-yellow colour, but is darker posteriorly. In twenty-four hours it changes colour, becoming brownish. It is formed of thirteen rings, and has three pair of feet. The head is flattened and rounded, and supports two short filiform antennæ. The mouth is formed of two maxillæ, furnished with four palpi. The nervous system presents more ganglia than in the perfect insect; but the stomach and biliary vessels are similar in both forms. The larvæ are very lively and active; and Zier says they are nourished on rotten wood and leaves of *Lonicera*, and on sugar. Applied to the skin, they excite itching.

3. The *pupa* state has not been described; in fact, the metamorphosis of the larva has not been observed.

4. The *imago*, or *perfect insect*, is the most interesting of all the forms, being that in which we employ the animal medicinally. In this state it has an elongated or almost cylindrical shape; its length is from six to ten lines (rarely longer); its thickness one or two lines: it has a golden green colour, and a nauseous unpleasant odour. The body is covered with whitish grey hairs, which are more numerous on the thorax than on the head, abdomen, or legs. The characters of the different parts are best studied under separate divisions.

(*a*) *Head.*—You will observe that the head is as broad, or rather broader, than the thorax, and inclined downwards; its shape is triangular or cordate: along the top there is a longitudinal furrow or depression. The eyes are large, and of a dark-brown colour; immediately in front of them the antennæ are attached,—they are filiform, and composed of eleven pieces or articulations, the two first of which are green and blue, the others black; the first is the thickest, the second the shortest piece. The mouth is composed of the same number of parts as other coleopterous insects; but there are some peculiarities noticed by Audouin. The mandibles terminate in a cutting edge, and have no teeth, though there is at the base a circular tubercle, somewhat resembling a molar tooth. The maxillæ are in part horny, in part membranous, and support palpi, each of which has four joints. The upper lip (*labrum*) is bilobed and narrow; the lower lip supports palpi, which are shorter than those of the maxillæ, and have only three joints.

(*b*) The *thorax* presents no characters essentially different from those of other coleopterous insects. The protothorax is not so large as the abdomen. The elytra are flexible, from four to six lines long, and from three quarters to one line and a half broad. On their upper surface they are of a beautiful golden or cupreous green colour, but beneath are brown: when viewed by transmitted light they are also brown. On their upper surface we observe three longitudinal ribs or veins, one of which is often confounded with the outer margin; and on examination by a magnifying glass we observe wrinkles. The wings are very thin, membranous, veined, transparent, and of a pale brown colour. The feet are from four to six lines long, smooth, and thin: there are five joints to the first pair of tarsi, and four only to the last. Audouin has described the following peculiarity connected with these parts: in the female, two small moveable spines are found at the junction of the leg with the tarsus, on all the limbs; whereas in the male this arrangement is found only on the two posterior pair, the anterior pair having but one spine; which, however, is strong, compressed, cutting, and placed on the median line. In this pair of legs, in the male, we observe a peculiarity not met with in the female: the first joint of the tarsus is hollowed out, so that when the spine is applied to it a hole is found. Now in the act of coitus, the male seizes the antennæ of the female, and locks them, as it were, in this hole. The last joint of the tarsi of all the feet, both of males and females, is furnished with a pair of claws, each of which is split, and forms in reality two.

(*c*) The *abdomen* is very soft; in the female it is broader than in the male. Superiorly it is of a greenish violet colour; at the sides near the stigmata it is black. Near the anus of the female are two articulated caudal appendages, somewhat similar to palpi.

Internal organization.—Let us now examine the internal structure of these animals, commencing with—

1st. *The nervous system.*—In this, as in other insects, the nervous system is two-

fold; namely, one part analogous to the cerebro-spinal axis of vertebrata, and another regarded as a kind of sympathetic system.

(*a*) The part which we may call the *cerebro-spinal axis* of insects, consists of a double nervous cord, running along the ventral surface of the body, and re-united at intervals by ganglia. In the cantharis there are nine ganglia; namely, two cephalic, three thoracic, and four abdominal. The first cephalic ganglion, or the bilobed brain, gives off the optic branches, the nerves of the antennæ, and two branches which may be regarded as the commencement of the single sympathetic system: posteriorly two twigs connect the brain to the second cephalic or subœsophageal ganglion: the œsophagus is placed behind the brain, before the second ganglion, and between these two twigs, so that the nervous system forms a kind of collar around it.

(*b*) The *sympathetic system*, or the nervous system of the œsophagus and stomach, has been recognized in the cantharis, both by Audouin and Brandt. It consists of two portions, a single and a double.

The *single* sympathetic system is composed of a single nerve. It commences at the two branches from the brain, as before mentioned. These, at their union, form a triangular ganglion (*ganglium frontale*), from which the nerve proceeds along the surface of the œsophagus to the stomach, where it divides into two, forming a small ganglion at the point of its division.

The *double* sympathetic system consists of four ganglia placed on the œsophagus, immediately behind the brain, two on either side of the single nervous cord just described, with which, as well as with the brain, they are connected by nervous twigs.

2. The *circulatory system* is formed by a simple pulsating dorsal vessel, extending from the head to the extremity of the abdomen.

3. The *respiratory system* is composed of ten pair (three thoracic, seven abdominal) of small openings, called spiracles, or *stigmata*, placed on the sides of the body. These open into the air-tubes, or *tracheæ*, which ramify and are distributed to all the organs of the body.

4. The *digestive system* must be next noticed. The before-described mouth terminates in the pharynx; this contracts into a long muscular œsophagus, which terminates at the metathorax, in the elongated fusiform stomach. On the external surface of this last-mentioned viscus we observe a number of transverse bands, formed by its muscular coat. At its termination in the intestine is a valve formed by the union of several small floating kidney-shaped bodies, attached by their external sides. The small intestine arises abruptly from the stomach, and is at first tolerably large, but soon contracts: it forms two or three curvatures, and then proceeds directly backwards. The last portion of the intestine being somewhat swollen, is considered as the cæcum, which terminates in a very short and narrow rectum.

The biliary or hepatic vessels consist of six very long, filiform, convoluted tubes, terminating anteriorly at the stomach, near the pylorus, and posteriorly at the intestine near the cæcum.

I may here notice the *adipose tissue*, or *rete*, of the cantharis. The function of the part which bears this name in insects is imperfectly known; some have regarded it as a kind of liver. It envelopes the alimentary canal, and is usually of a white or yellow colour.

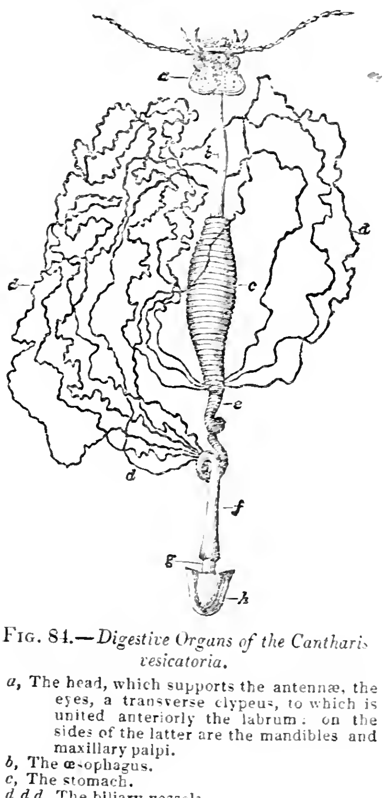

FIG. 84.—*Digestive Organs of the Cantharis vesicatoria.*

a, The head, which supports the antennæ, the eyes, a transverse clypeus, to which is united anteriorly the labrum: on the sides of the latter are the mandibles and maxillary palpi.
b, The œsophagus.
c, The stomach.
d d d, The biliary vessels.
e, The intestine.
f, The cæcum.
g, The rectum.
h, The last ring of the abdomen.

5. *The sexual apparatus.*—In the *male* we find a pair of spherical testicles, granulated externally; two vasa deferentia, which have a ringed appearance, and enlarge as they proceed towards their termination; three or four pair of tubes, the functions of which are imperfectly known; a common spermatic duct; and a penis. The three or four pair of tubes just alluded to are described differently—Brandt saying they are three, Audouin four pair: the latter writer calls them seminal vesicles, while others term them epididymoid vessels. The penis has three barbs or hooks at its extremity, and is enveloped by a sheath composed of two pieces, each hooked at its termination.

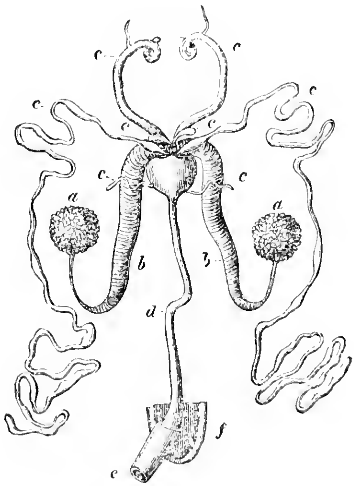

FIG. 85.—*Male Genital Organs, from Audouin.*

a a, Testicles.
b b, Vasa deferentia.
c c, *c c*, *c c*, *c c*, The four pair of vesiculæ seminales, or epididymoid vessels.
d, The common spermatic tube.
e, Portion of the intestinal tube inverted.
f, Last abdominal ring.

The *female* organs consist of two large, hollow, egg-shaped, ovaries: the cavities of which are called *calyces*. On their external surface is placed an immense number of fusiform egg tubes. From each ovary (or calyx) arises an oviduct; and the two ducts joining form the common oviduct, or egg canal, the lower portion being termed a vagina. Into this common oviduct passes a tube from a vesicular bag, called *spermatheca* (the *vesicule copulatrice* of Audouin), and also of other appendages (called sometimes sebaceous glands.)

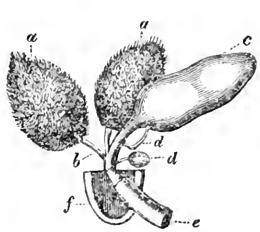

FIG. 86.—*Female Organs of Cantharis vesicatoria.*

a a, The ovaries covered by the egg tubes. Each ovary sends out an oviduct, *b*. The two ducts unite to form the common oviduct, which receives the excretory tube of the *spermatheca*, *c*, and of other appendages, *d d*.
e, Portion of the inverted intestine.
f, Last abdominal ring.

I must refer those who feel interested in the amours of these animals to Audouin's "*Recherches*," in the "*Annales des Sciences Naturelles*." Suffice it here to say, that the male loses his penis, and shortly afterwards dies.

Geography.—It is probable that this insect was originally a native of the southern parts of Europe, especially Italy and Spain. It is, however, now found in France, Germany, Hungary, Russia, and other parts of Europe. As its food is vegetable, it is found on trees, particularly those belonging to the families *Oleaceæ* (as the ash, the privet, and the lilac), and *Caprifoliaceæ* (as the elder, and several species of Lonicera.) It is easily recognised at a considerable distance, by its disagreeable odour, which is exceedingly unpleasant, and even dangerous. It occasions public walks and promenades, near which it may be found in large quantities, to be deserted.

Mode of catching them.—In the south of France these animals are caught during the month of May, either in the morning or evening, when they are less active, by spreading large cloths under the trees, which are then strongly shaken, or beaten with long poles. The catchers usually cover their faces, and guard their hands by gloves. Various methods have been recommended for killing the insects; such as exposing them to the vapour of vinegar (the practice mentioned by Dioscorides), or of hot water, or of spirit of wine, or of the oil of turpentine. Geiger states, that if destroyed by dropping oil of turpentine into the bottle in which they are contained, they are not subject to the attack of mites. But I believe they are more frequently destroyed by immersing the cloths containing them in hot vinegar and water, and then drying on hurdles covered with paper or cloths.

Preservation.—The active principle of cantharides being volatile, they ought to be preserved in glass vessels well stoppered, as by long exposure to the air their activity must be in some degree impaired.

Cantharides are liable to be attacked by several insects, which reduce them to powder. These are, a species of mite (Geiger says the *Acarus domesticus*), a moth (*Tinea flavifrontella*), and two coleopterous insects, namely, the *Anthrena museorum*, and *Hoplia farinosa*. Notwithstanding what Limouzin-Lamotte has asserted to the contrary, it seems well established that worm eaten cantharides are less active than those which have not been attacked, and that the deterioration is in proportion to the number of mites present, the dust and excrements of which are not vesicant. Various proposals have been made to guard our blistering flies from these parasites. According to Farines camphor will not answer. Some recommend placing little bags of the chloride of lime in the vessel containing them; or dropping into the bottle a little spirit of wine, or oil of petroleum, or pyroligneous acid.

Commerce.—Cantharides are imported from St. Petersburgh in cases, each containing 160 or 170 lbs.; and also from the port of Messina, in Sicily, in barrels or cases holding about 100 lbs. The largest quantities are brought over towards the latter end of the year. By reference to the Trade List published at the Custom House, I find that the quantity of cantharides on which the duty of one shilling per pound has been paid is as follows:—

	lbs.
For the year 1834	20,085
For the year 1835	17,468

However, it must be remarked that this statement refers to the ports of London, Liverpool, Bristol, and Hull only; but it will give a tolerably good notion of the quantity annually consumed in Great Britain.

Varieties.—In commerce the cantharides from Petersburgh are considered the best; they are larger and more copper-coloured than some which I have received from France; the latter being greener and smaller.

Chemistry.—Very little advantage can be gained by discussing the notions entertained by the old chemists, respecting the active principles of cantharides. Suffice it to say, that by some the operation of these insects was referred to the sharp, needle-like, and pointed form of their particles; by others to an imaginary acrimonious salt; by Neumann to resin; by Thouvenal to green wax; and by Beaupoil to various constituents, namely, to a green oil, a yellow and a black matter. The following tables shew the results of Thouvenal and Beaupoil's analyses:—

Thouvenal's Analysis.

1. Extracted by water, a reddish, yellow, bitter extractive	216
2. Extracted subsequently by alcohol, a green, acrid, odorous wax	60
3. Extracted subsequently by æther, a yellow wax	12
4. Insoluble residuum, or parenchyma	288
	576

Beaupoil's Analysis.

		Gros.	Grs.
1. Black matter, insoluble in alcohol, but soluble in water		1	2
2. Yellow matter, soluble in water, alcohol, and æther		1	2
3. Green oil, insoluble in water; soluble in alcohol and æther		1	8
4. Parenchyma	Animal matter	4	36
	Phosphate of lime	0	12
	Carbonate of lime	0	2
	Sulphate and muriate of lime	0	4
	Oxide of iron	0	2
5. Acid (phosphoric ?)	quantity undeterminable.		

In the year 1810 Robiquet announced the discovery of a new principle, to which the active properties of the blistering beetles were referrible, and to which Professor Thomson, of Glasgow, applied the name of *Cantharidin*. The other substances which Robiquet obtained from these animals he found had no vesicating property.

Robiquet's Analysis.

1. *Cantharidin.*
2. Green fixed oil, soluble in alcohol.
3. Fatty matter, insoluble in alcohol.
4. Yellow viscid substance, soluble in water and alcohol (osmazome?)
5. Black matter, soluble in water, insoluble in alcohol.
6. Yellow matter, soluble in æther and alcohol.
7. Free acetic and uric acids.
8. Phosphate of lime, and phosphate of magnesia.

I may remark that there are probably other principles in cantharides than those just mentioned. The strong and fœtid odour of these insects, no doubt, depends on a *volatile oil*; and Orfila is of opinion that this oil is one of the active principles. Odier has obtained from the elytra, and other parts of many coleopterous insects, 25 per cent. of a substance which he has designated *chitine* (from χιτωὶν, a coat, or envelope); because it forms the basis of the hard parts. Though cantharides are not particularly noticed, yet they must possess it in common with other beetles. Lastly, it would appear there must be a *colouring matter* unnoticed in Robiquet's analysis; for Chereau has found that the green and gold matter composing the elytra is insoluble in water, alcohol, æther, and oil.

Let us now examine the most important constituents of Spanish flies separately.

1. *Cantharidine.*—I have already mentioned that this substance was discovered by Robiquet, in 1810. In addition to the name it usually bears, it has also been termed *vesicatorin*, or the *vesicating principle of cantharides.* In Leopold Gmelin's *Handbuch der Theoretischen Chemie,* it is called "*cantharidcn camphor*;" being classed among the solid volatile oils, which some of the German chemists denominate camphors (Berzelius terms them *stearoptenes*, Bizio, *steurisin*). This principle is not peculiar to the cantharis vesicatoria, but has been found both by Dana and Robiquet in the *lytta vittata*, or potatoe fly of America, and by Brettonneau in the *mylabris cichorei.* Most probably it (or some analogous substance) exists in all blistering insects.

Extraction.—There are two methods of procuring cantharidine; one proposed by Robiquet, and another by Thierry.

Robiquet's process. — (*a.*) *Prepare a watery extract* by repeatedly boiling roughly powdered cantharides in water until nothing soluble is left. Filter and evaporate to the consistence of a soft extract. A brown mass is by this means obtained. I would here remark, that, by the boiling, a portion of the cantharidine must be volatilized; for the vapour strongly irritates the eyes and affects the kidneys and bladder, causing pain in the loins, with frequent desire to pass the urine.

(*b.*) *Digest the watery extract in alcohol,* which takes up the active part. Robiquet calls the insoluble residuum a *black* matter; but I find it to be, when moist, dark brown, and when dry, light brown. The alcoholic tincture is to be distilled until it has acquired a thick consistence. Robiquet calls the residuum a yellow substance: that which I obtained has the appearance of treacle.

(*c.*) *Digest the alcoholic extract in æther.* The slightly-coloured solution thus obtained is allowed to evaporate spontaneously. By this means a yellowish brown extract is obtained, intermixed with very small crystals.

(*d.*) *Wash the ætherial extract with alcohol,* which dissolves the colouring matter, leaving the cantharidin. This is to be removed, and dried between folds of blotting-paper.

This process is very expensive, and gives very little product.

Thierry's process. — Macerate cantharides in alcohol, æther, or a mixture of the two (*alcohol éthéré*), for several days; then distil the tincture. The residuum, when cold, consists of two layers: the lower one a brown liquor, the upper one a green oil; on the surface of which are seen crystals of cantharidin. These two liquids being separated, the oil is to be placed on a filter, and, by the assistance of a gentle heat, it passes through the paper, leaving the cantharidin. To purify the latter from any oil, press it between folds of blotting-paper, and dissolve in boiling alcohol: as the liquid cools, the cantharidin is deposited.

The *properties* of cantharidin next deserve attention. This substance crystallizes in the form of micaceous plates, which are fusible, forming a yellow oil, which by a still stronger heat is vaporizable, forming white vapors, which condense into cantharidin in small needles, unchanged in its blistering properties. Dana regards it as an organic alkali, but without any just grounds; for it will not restore the blue colour of litmus paper reddened by an acid. Gmelin's opinion, that it is a solid volatile oil, seems to be correct. When isolated, it is not soluble in water, but, combined with the other constituents of cantharides, it is; the yellow matter probably being the principal agent in rendering it so. This, then, is the reason why an aqueous infusion of the flies contains cantharadin in solution. Cold spirit, digested on can-

tharides, extracts cantharidin; which it can only do by the agency of some of the other principles of the flies. It is easily soluble in æther, oils (volatile and fixed), and hot spirit of wine; and from the latter it separates as the liquid cools. Two or three practical points here suggest themselves, to which I shall have occasion hereafter more particularly to direct your attention. 1st. The solubility of cantharidin in oils, points out the impropriety, and even danger, of using these liquids as antidotes, and also why a blistering plaster acts equally well through paper or muslin. 2dly. In medico-legal inquiries, connected with cantharides, we may employ æther to extract the vesicant principle (that is, the cantharidin). Concentrated boiling sulphuric acid dissolves cantharidine: the solution is slightly brown; when diluted with water, it deposits small needle-like crystals of cantharidin. Boiling nitric and muriatic acids dissolve it without changing colour; the solution, by cooling, deposits it. Cantharidin is dissolved by potash and soda; but when concentrated acetic acid is added, it is precipitated. Ammonia is without action on it.

No analysis of cantharidin has yet been made.

2. The *odorous volatile oil* is asserted by Orfila to be one of the active principles of cantharides. I have already mentioned that cantharidin is to be regarded as a solid volatile oil; and it is not at all improbable there may be also a liquid one. That there is a volatile odorous matter is certain; but the doubt is as to the activity of it on the system: if it be active, it is curious that its action is of the same kind as cantharidin. If water be distilled from cantharides, we obtain a strongly odorous milky liquid: the vapour of this will affect the eyes like cantharidin, and also the kidneys. Now I suspect that this active volatile oil, or toxic principle of Orfila, is merely the volatile cantharadin combined with some odorous matter. That cantharadin is volatile, even at low temperature, is proved by the following fact. One of Robiquet's pupils, who was watching its crystallization, felt acute pain in the conjunctiva, which was followed by inflammation accompanied with small phlyctenæ, and loss of sight for many days. Robiquet, who was not so near, suffered but slightly.

This volatile odorous oil of cantharides is regarded by some as the principle to which these animals owe their action on the nervous system, and some have added the urinary organs also.

The cantharadin and odorous oil of Spanish flies appear to reside principally in the sexual organs. Both Farines and Zier tell us, that the soft contain more active matter than the hard parts. It appears also that the posterior is much more acrid than the anterior portion of the body; and Zier says the ovaries are particularly rich in this active matter. If so, it is evident we ought to prefer large females to males. It is a well-known fact that the odour of these animals becomes much more powerful at the season of copulation than at other periods; and that persons sitting under the trees in which these insects are, at this season more particularly, are very apt to be attacked with ophthalmia and ardor urinæ.

3. *The other constituents* of cantharides will require a very brief notice.

a, The *black*, or, as I should call it, greyish brown, matter left behind by digesting alcohol in the watery extract, though soluble in water, is not so in alcohol. Robiquet proved by experiment that it had no vesicating property.

b, The *yellow*, or brownish, *osmazome*-like substance is left undissolved when æther is digested on the alcoholic extract. Berzelius says it is an extractiform substance reddening litmus paper, and appears to contain lactic acid.

c, The *green fixed oil* is obtained by digesting alcohol on cantharides which have been repeatedly boiled in water. A green tincture is by this means obtained, and by spontaneous evaporation the alcohol is got rid of, and a green non-vesicating oil left behind. Barbier states that a drachm of this had no effect on dogs.

d, The other fatty constituent of cantharides is obtained by allowing the ætherial tincture of these insects to evaporate spontaneously; then wash the oily residue with hot alcohol, to dissolve the cantharidin. This fatty oil is distinguished from the green one by its insolubility in alcohol.

e, The yellow substance soluble in æther, and separable from the impure cantharadin by alcohol, has not been much examined.

f, The free acid found in the aqueous infusion, or distilled water of cantharides, was taken by Beaupoil for phosphoric acid; and it is not I think improbable that a portion of this acid may be present; but Robiquet has shewn the existence of acetic (or is it lactic?) acid even in the living flies; and in fresh flies uric acid also. In noticing this last substance, Robiquet remarks that it is curious that these insects, which have such a marked action on the urino-genital system, should present in their composition many points of resemblance to urine. The metallic brilliancy is probably in part owing to the mechanical arrangement of the constitu-

ents, and is, therefore, to a certain extent, independent of their nature.

Tests for cantharides.—On many accounts it is highly desirable that we should have some chemical means of recognizing cantharides both in substance and in solution. I much regret such means are still wanting. You will find in Orfila's Toxicology the effects of various chemical re-agents on solutions of cantharides. In my opinion, none of the results yet obtained are worth much; and I say this after having examined the action of a large number of substances on these flies. That this is also Orfila's opinion is evident from the following remarks:—"If the characters furnished by the re-agents should differ from those I have described, the practitioner must pay no regard to them in deciding on the presence or absence of cantharides, for animal substances present in the different menstrua very complicated phenomena, which are little understood, and consequently liable to lead into error." In the absence, therefore, of chemical proofs, we may resort to the following:—

1. *Zoological characters.*—It is very unlikely, however, that the flies will be met with in a sufficiently perfect form to judge of their zoological characters.

2. *Physical characters.*—In all powders of cantharides you may distinguish golden green particles; these may be separated from the other contents of the stomach by immersing them in boiling water: the fatty matter rises to the surface, while the cantharides powder falls to the bottom. Orfila has recognized these particles in a body nine months after interment; so that they do not readily decompose even when mixed with decaying animal matters. Recollect that there are many insects which have the same golden green colour, but are without vesicating properties; and *vice versâ*, there are many insects which vesicate, but which have not a golden green colour.

3. *The symptoms* hereafter to be mentioned.

4. The *lesions* also to be spoken of in the next lecture.

5. The *physiological effects* of the suspected matters. In some cases this is the only mode of detection that can be adopted. The best method of proceeding to determine these effects is the following:—If the suspected matter be a liquid, evaporate to the consistence of an extract; then digest in repeated quantities of sulphuric æther. The ætherial solutions are to be mixed, and allowed to evaporate in the air: the vesicating properties of the residuum may be determined by applying it to the inside of the lip or to the arm. If the suspected matter contain solid particles of cantharides, these will be recognizable in part by their colour, and in part also by digesting them in æther, and proceeding as just described. In the *Annales d'Hygiène publique* for April, 1835, you will find an illustrative case, in which Barruel demonstrated the non-existence of cantharides in a suspected liquor, and the presence of powdered cantharides in some suspected chocolate.

Adulteration.—The goodness or quality of cantharides may be recognized by their odour, and freedom from insects of all kinds. Sometimes the powder, but more commonly the plaster, is adulterated with powdered euphorbium. I have been informed by persons well acquainted with the fact, that it is a common practice amongst certain druggists to mix one pound of euphorbium with fourteen pounds of powdered Spanish flies. I regret that I have no means of detecting this adulteration in the plaster, except by observing its diminished vesicating power. I have on several occasions strongly suspected this practice, by finding that the plaster from certain druggists did not vesicate so powerfully as that which I knew to be genuine. If you digest alcohol on powdered cantharides mixed with euphorbium, and then add a few drops of this tincture to a glass of water, there will be a greater milkiness than if no euphorbium were present; but it is not a test on which much reliance can be placed. I have been informed that the dregs of the tincture of cantharides bottle have been sometimes used in the manufacture of blistering plaster.

CLINICAL LECTURE

ON

COMPOUND FRACTURE OF THE FEMUR.

Delivered at the Middlesex Hospital School, Jan. 4, 1836.

By Sir Charles Bell.

Gentlemen,—I wish I could speak to you familiarly and confidentially. You may perceive that what I am addressing to you goes abroad to the world; and instead of speaking to the half-educated, (if you will permit me to say so without offence) my unpremeditated words, when printed in the journals, appear to be ambitiously addressed to the learned part of the profession. I beg, then, to say they are not.

But this is the misfortune of the times in which you enter upon your studies, that every thing is printed; and it becomes an injury to the profession, and

especially to the schools, because it is placing in the hand of the journalists the character and reputation of the teacher; giving this power to men who may, or who may not, be the best judges of what is right and sound in doctrine, or honourable and correct in conduct.

There are professors acknowledging that their receipts have been trebled through the influence of the press: this is a new thing among us. The professors, or the teachers, of London, now marshal themselves to go up to the Ministers of State, who are understood to be in the act of imposing laws on the profession, and these gentlemen say, "Look you here, what a school we have at our back, and therefore give us privileges—make us a college." Had I the ear of these Ministers, I would certainly pray them to look to the recent means of obtaining popularity, and the consequent degradation of the schools of the metropolis.

You are the sufferers in this state of things; for instead of the teacher recollecting what he was when in your circumstances, remembering the errors and the misconceptions which he entertained at your age, and therefore bringing himself back, if you will allow me the expression, to your condition, he is thinking of another tribunal altogether, and you lose the advantage of that friendly footing that you ought to be on with the gentleman under whom you enter in the hospital, and especially the free and unembarrassed communications on the questions of practice. However, we must endeavour to forget all this, and enter the best way we can upon our duty.

Once more, then, I call your attention to one of those dreadful accidents which bear upon the great questions of surgery. You are not unprovided with books on stricture, fistulæ, and lues, for these works are published daily; but they do not touch upon the great principles of surgery, which ought to be with you at present the paramount objects.

Observe, gentlemen, that there is some force of imagination necessary to the study of surgery. "What!" you say, "poetical imagination?" No; but it is necessary, by force of imagination, to anticipate much—to place yourselves in that condition which, sooner or later in your professional career, you must be in; this is almost as necessary as it is to have a precise notion of the condition in which your patient shall be, for without it what avails the aphorism of practice, since you cannot apply it? By anticipating the terror and confusion of friends who crowd around a patient who has received some terrible accident, you are prepared to act your part,—which is, to be collected whilst others are distraught and palsied with terror—which is to be decided while every one else is jostling in ineffectual efforts to afford relief. This is your professional character; not a mock gravity, with the head of the cane at your chin, but a firm and manly aspect, and full of resources which you have long contemplated, and have anticipated the occasions for putting in practice. More especially in regard to the question which is to occupy us to-day, it is necessary that you should have a distinct notion of the case. You must not only know the nature of the wound, but you must have studied the effects of a severe accident on the constitutional powers—how the patient will be found lying hardly alive, pale, breathing anxiously, incapable of speaking, his pulse feeble, and his extremities cold. When you have formed, I say, by force of imagination, a correct notion of the patient's condition in such kinds of wounds, you have gone far to determine the question of what is proper to be done. I give you this as an instance why you ought to be looking forward in anticipation of scenes in which you are to be engaged.

I wish to draw your attention, then, to the case of a lad with fracture and laceration of the thigh, close to the hip-joint. At four o'clock on the morning of the 24th December I am brought here, and I find a lad desperately hurt. There is a deep wound in the groin and thigh; there is a great ragged flap formed of the integuments on the inside of the thigh and adductor muscles; there is a more irregular wound, more bruised, on the outside of the thigh; there is a separate wound just below the groin, and in front of the thigh; the femur is broken, and its upper portion stands out three inches, and its sharp extremity is cocking directly up out of the wound. There has been great hæmorrhage; the tourniquet is around the upper part of the thigh, but it is not now screwed up. The lad is very pale; the pulse feeble and easily compressed; the extremities cold; the breathing anxious. Fourteen hours have elapsed since the accident. It is one of the accidents from the railway; the heavy sharp edge of a wheel has passed over the upper part of the thigh, near the groin. You will, of course, at once, in these circumstances, anticipate the determination of the consultants, that amputation must be performed.

But before I proceed to consider this case, and all the questions that arise out of it, I wish you to regard these observations of mine not as speculative, but as the observations of one who has seen, perhaps, as much as any man can boast of—if it be

a thing to boast of at all—certainly as many cases of desperate fractures of the thigh-bone as to enable me to have an opinion on these cases. The late Inspector-General, Mr. Knight, employed me in giving lessons of anatomy to the young surgeons going out to our armies abroad; and if the pupil and brother of John Bell had not been excited early to attend to the questions of military surgery, this was an occasion which called for him to be particular in studying that department; in fact, I lost no opportunity of doing it.

During our long war, after the engagements of our ships at sea, or of our armies, our men were brought home in bands, and lodged in hospitals here, and I assiduously attended to them, examined their wounds, heard their narratives, and sometimes assisted at operations. Then came the disastrous battle of Corunna: history now tells you that the men who were wounded were carried to the transports without arrangement, in different vessels from their surgeons, and consequently they came to the shores of England just as they left the field. On that occasion I left lectures and practice (which people would say I ought to be most interested in), to wait the landing of these men. I marked their condition, followed them from the strand to the hospital, attended assiduously upon them there, and studied the rules which decided the practice of the army and navy surgeons; for both were in attendance.

On some occasions I doubted the expediency of the practice; and after-experience confirmed my objections. Another occasion offered in the battle of Waterloo. When I heard of that great battle I set off but ill prepared, and reached the field of our operations several days before the surgeons despatched by government. There was, indeed, sufficient field for observation. The newspapers said 30,000 were *hors de combat*. I can only tell you that they lay by thousands. I was engaged with my note and sketch books until I found that numbers were brought into Brussels in the most desperate condition, and without surgical assistance. There was no blame: the regimental surgeons had marched on with the army to Paris, and the wounded of all nations were brought in hourly. I could not, therefore, deliberately study the individual cases any longer; I was forced to offer my services; they were accepted, and I laboured with these men for three successive days and nights with little intermission. I mean by this, gentlemen, first to impose upon you my conviction of the importance of the subject, and then to convince you that I am not speaking here as a speculative person sitting at home, but that I have witnessed all the difficulties the army surgeon has to contend with, and have felt the responsibility of acting in the varieties of cases the most desperate.

After all there is not so much difference as you might imagine between the practice of the hospital and the military surgeon. Gunshot wounds, certainly, is a subject of itself, in so far as you must take up distinct principles when you have to speak of a ball, a round or obtuse body sent with incalculable velocity through the body—the thigh, for example. This is undoubtedly a distinct subject, but it is not the question with which we have to do to-day. When the sides of a ship are struck with round shot, and splinters scattered; or when cannon-shot tear up the gabions and the temporary breast-works in the field; or when men are wounded by the bursting of shells, the great questions of surgery present very much as they do in the hospital—as, for example, in this lad. Such wounds I have long since considered; and it may some time or other become my duty to my office, if not to myself personally, to take a leaf out of some of the volumes of Military Surgery, and to place it in my portfolio for lecture; and if I be challenged, I will just say as a northern Duke did in respect to his boroughs, "may I not do what I choose with my own?"

In the case of this lad the operation is determined upon; and when you contemplate the patient in the exhausted condition I described, I think the first idea that will occur to you is the correct one, as it is the natural one—that it is our duty to save him, as far as possible, from a second shock. It was with this idea that I placed the amputating knife within the irregular flap which was on the inside of the thigh, and carried it round on the outside, inclining the knife, and cutting as far as I dared venture, making a flap there also. That this attempt was imperfectly accomplished was owing to the bruised condition of the wound. The whole mass was then drawn back with the split cloth, but could not be so effectually drawn back as you might imagine, being so high in the thigh; and the bone was sawn across. I then looked to the ragged face of the stump, and those parts which hung out I cut clean off. You might have observed, that as I took hold of the muscle, and cut it across with the sweep of the knife, the lad felt no pain, and there was no additional disturbance from this practice. The artery bled freely although the tourniquet was applied; and upon this I shall make some remarks presently.

It is our duty to avoid, if possible, in these desperate circumstances, a second shock to the constitution. Now we use

that term metaphorically. No doubt there is such a thing as a mechanical shock—as, for example, when a man, standing firmly upon his feet, has a limb carried off by a cannon-ball. There is then a great mechanical shock to the whole nervous system, such as you are familiar with in respect to the brain in concussion. That most admirable surgeon, Mr. Cline, mounting a young horse, was thrown, and on his recovery he found that he had received a shock all over, and said, "Now I recollect the observation of John Hunter, that to kill an eel, you must not tread upon its head, but you must take it by the tail and smack it upon the ground, and it dies, because the shock is then given to the whole nervous system." He added, "I feel that the shock was not in my head, but over my whole body." There is certainly such a thing as a shock, a vibration, a mechanical influence over the whole body; but when I use the term *shock* now, I do not mean that, but an influence upon the life. It would be in vain to endeavour to ascertain what this was, unless we knew something more than we do of the life itself. We see, however, that great pain, that the lopping off of a large portion of the body, produces an influence upon the living powers. Neither the brain, nor the heart, nor the nerves, nor any thing you can mention of vital parts, are hurt, yet the constitution, or the powers of life, suffer. You know, for example, that in the case of the lower animals, you may cut them into portions, and yet they survive. But when you come to animals higher in the scale, and especially man, you find you cannot cut off a quarter of the body, and yet leave the body in life and health. Whatever this influence may be, it is that I now mean. When a whole limb, almost a quarter of the body, is cut off, however dexterously, however suddenly, whether removed by an engine or by the surgeon's knife, there comes to be an influence upon the life of the remaining body. The greater part of the thigh having to be taken away, instead of putting the knife round and cutting through all the parts again, I put it within the flap, and brought it along the original wound, so as to diminish, as it were, the severity of the second operation—the second shock upon the system; because I think every thing else yields in importance to this. The patient is in that condition, that if further and extreme violence be done, and if, for example, the whole parts are cut through again, he will probably sink under the operation.

But you will say that this flap was a lacerated wound; and we find it stated in our books of surgery "that contused and lacerated wounds must suppurate or slough." I do not hold that opinion to be correct. I have found a lacerated wound adhering most kindly. I have seen a man tossed by a bull, the horn going in at the side, and coming out at another hole, at which the bowels protruded; the bowels were reduced, and the lacerated and torn wound healed kindly by the first intention. So upon other occasions, when people have fallen on spikes and been torn, I have found a lacerated wound adhere just as well as if it had been made by a surgeon's knife; and accordingly, in the case of this lad, on the fifth and sixth days of dressing, you saw no sloughing.

I then put the flaps together, and dressed the stump; but this practice is objected to: it is at least a contested point. I consider it in this light: here is a large open surface; you look around for something to apply to that surface—something soothing. Surely you would like something warm, and soft, and moist; and if it were possible, something alive, that there might be sympathy between the surfaces. What, then, is better than the opposite flap of the same limb?—for by this two objects are gained: the most soothing application that you can put to this extensive lacerated surface, and probably, in addition to this advantage, adhesion; and if there be adhesion, just in proportion to its extent there is a diminution of the excitement and inflammation; and so much is removed of that influence which you dread on the constitutional powers. What, then, can be the meaning of a rule of some surgeons, not to bring the flaps together, lest they should adhere, but rather to dress them separately? Undoubtedly it arises from this; that if a man has his limb amputated in the field, in the hurry of passing from tent to tent in the rear of the army, and if the surgeon puts on strapping, dressing, compress and roller, and the patient be left, perhaps, for a whole day, or indeed much longer, there arise great pain and serious mischief: the stump swells, with pain, spasm, inflammation, and fever. What does this proceed from? Not from the manner of dressing, but from neglect,—necessary neglect, it may be. You have only to mark the necessity of an early visit; that if you have operated on a patient, and dressed him, brought the surfaces and the edges into contact, applied the straps, nicely put down the compresses, brought your cross cloth and roller over the face of the stump, and made all comfortable and firm, you impose upon yourself the duty of visiting the patient in a few hours, and asking him if there be pain and tension of the stump. If there be pain and increased

throbbing, you must loosen your cross straps,—you must cut across some of the rollers,—you must even divide the plaister straps, or you will have tension, following that inflammation, and great distress,—perhaps spasm. But when such mischief ensues, it is owing to the neglect of the evening's visit, and not to any thing wrong in the operation or dressing.

Again, some others say, I shall not dress this patient till two or three hours after the operation. There is reason in this; and we have a parallel case when a bone is broken. A patient comes into the hospital with a fractured limb; perhaps there is a new house-surgeon, who has not been attentive to his previous duties as a dresser. He rolls up the limb as soon as he is called, and applies the splints, and over these splints the bandages. The man suffers in the evening in an excessive degree; and if he be left till the morning there is vesication between the bandages, and perhaps mortification of the foot or hand. The reason of this is, that the young surgeon has done up and bandaged this limb before the coming on of the tumefaction. To save appearances with the patient's friends, take the trouble of explaining what will follow, and show your care for the limb by placing it properly, and defending it against any accidental movement; but see that you do not bandage before tumefaction has begun, and, indeed, before it has subsided; or if you must make a show of *setting* the limb, as the vulgar expression has it, mind that you return to divide your bandages, and free them under the increasing tumefaction. Now this is a parallel case. If you have that sort of patience, and if you have time to spare, you may wait and dress the stump in the afternoon; but if you dress it immediately, you must recollect that tumefaction from the stimulus of the knife must come on, and you must manage accordingly. Such I apprehend to be the reason why great inflammation and bad suppuration come on by immediate dressing, and therefore it is that some of the continental surgeons will not bring the flaps together,—will not take advantage of the two soothing surfaces meeting together,—will not take the chance of a certain portion of adhesion which is in some measure to stop the inflammation, but put in *charpie* between the surfaces, and allow suppuration to be established before they bring the flaps together.

Some might have thought in this case of taking off the limb at the hip-joint. I hope and trust that the desire of distinction by doing this operation has passed away with the novelty of it. I remember going round my collection in the museum of Windmill-street, many years ago, with Assalini, the celebrated Italian surgeon, to whom you are indebted for some neat surgical instruments, and who was certainly one of those who thought more of the operations of surgery than of the great principle we are considering. We came at last to a diseased bone—the femur—when I found my Italian friend expressing himself in a language familiar to all nations, but suprisingly so to the natives of the South. He paused; he stood erect, put the palms of his hands together, and mounting his eyes, said, "Ah! I let the opportunity pass of taking off a young man's limb at the hip joint!" I remarked that it was just as well that he had not; that his conscience was just as clear as it might have been then. Now that disposition pervaded all the surgeons of the continent; they had a notion, that by dexterous execution with the amputating-knife, they would establish an unfailing character for surgery. That is what I mean when I say that I hope the desire for distinction has passed away with the novelty of the case. Now would that lad have been in as favourable circumstances had I cut out the bone? Here was a return to the principle under consideration, viz. the extent of the injury to the powers of life. The surfaces must have been very extensive indeed, the wound longer, and the pain protracted. Then, to dissect the head of the bone from the articulation, is easy enough to any man educated in a dissecting-room; but how far does that consideration influence the question as regards the patient? The time spent in the disarticulation, and the extent of surface exposed, would, I believe, in this case, have been attended with death: I have not a question about it. I do not deny that a case may present in which the operation shall be required. A portion of bomb-shell may so shatter the head of the bone, and tear away such a mass of the thigh, that we can do no other than dissect the articulation, in order to make a flap: that case, however, is a very desperate one. But I venture to say that there is no form of musket-shot, nor is there any condition of diseased bone, that will make a case for the amputation at the hip.

I hope you have looked at this boy whilst he was dressed. I hope you looked to the state in which the wound is found about the seventh day; for that is ten times more important to you than any thing which could come from my lips.

You observe that the amputation was an irregular one; and in these cases it is necessarily irregular. You may take the general principle of saving skin to cover the muscle, and of saving muscle to cover

the bone; but when you come to a case of this kind, you must apply the principle differently from what you do in the circular amputation;—you must find the skin where you can, and the muscle wherever the mass is; but what I wish you to attend to is, that as a large portion of the surface in this case was made by the original wound, it presents to you now an expanded efflorescent mass of granulations. It does not exactly represent, but it reminds me of those cases which I saw that came from Corunna. When the limb has been carried off, and the stump left without assistance, in seven days the whole is as a part of this large stump, red and soft, with exuberant granulations. Such was the condition of the stump of Sir William Maxwell, whose arm had been carried off by a cannon-ball. There was extraordinary efflorescence, a cauliflower-like excrescence of the interior of the ragged flaps, the muscles were granulating, and the detached bones were adhering to the muscle. This, however, is the effect of the want of pressure, of proper dressing. You must attend to this, giving sufficient pressure without bringing your patient into that condition of pain and excitement which comes from tight bandaging. In dressing this boy the difficulty is to bring forward the mass of flesh, and to give it sufficient compression, so as to prevent it from expanding and efflorescing in the manner I have described.

I think that even in your day, in your experience in this hospital, we have found, that after dreadful accidents, giving occasion to amputation, our patients have sunk about the fifth day; so let me hope that this lad has passed that period of danger—I mean the danger from the shock and the rising inflammation on the constitution: if he sinks now, it will be from the extensive discharge and debility.

The next point in this case to which I beg your attention is, the remarkable erection of the bone,—it stuck straight up. As anatomists, you know how this must happen. As we sit there is a great weight upon the femur; and not only so, but all the posterior muscles are counteracting the anterior: but when the bone is broken, the weight that should depress it is gone, and the posterior muscles are detached at their insertions. There is a lesson to be learned here. The dresser will tell you that he has the greatest difficulty in pressing down the stump: as he presses it down, the muscles and integuments cover the end of the bone; but as he ceases to press, the bone jumps up again. Here is the demonstration [alluding to several specimens of fractured thigh-bones]. I think, by the by, that it has been in anticipation of this remark that they have placed these bones before us to-day, and I am very glad of the hint. I once made up a case of twelve fractured thigh bones, in all of which the upper extremity was cocked up; and you see in this specimen that the upper portion is above the lower portion of the bone. I did not know that we had so many examples of fracture. The fact is important, because it is a clear demonstration to you of the necessity, in amputation, of raising up the thigh, and keeping the saw horizontal whilst you saw it across, otherwise you are deceived. The bone appears at first pretty deep among the flesh, but you no sooner let the stump loose than up it goes, and the bone starts out from the flesh. The principle is, of course, applicable to the fracture of the thigh. You try in vain to keep down the bone; and failing, you may have distortion and retraction. You see, then, the object in the inclined plane; the inclined plane allows you to raise the lower part of the limb, and to bring it into that position which the muscles give to the upper part.

The next reflection regards the artery, and the application of the tourniquet. The tourniquet was applied here high in the thigh, but I was sure that it would not be effectual; and the fact is, that when I cut across the artery, you saw that it bled freely. Why then, you will ask, did I wish the tourniquet to be applied at all? Would it not have been better to have trusted to the assistant's thumb to compress the artery at the groin? Yes, in regard to the artery this would have been effectual; but still there would have been blood lost, which this youth could ill bear; for, as you have seen, the lad was pale and cold, and low, and must have sunk had much blood flowed. By compressing the groin you would have commanded the main artery; and when it was cut across there would have been no jet from it; but, in the meantime, the blood would have been poured out from the face of the stump, coming round by the vessels of the hip, the gluteal, the ischiatic, and obturator arteries.

Remember that the notion has been that the pressure you use at the groin is ineffectual, because, on proceeding to the operation, the artery bleeds notwithstanding. But it does not bleed because it is uncompressed, but because of the freedom of the inosculation coming round; and therefore, if at any time you are to operate by compressing the artery, your assistant's hands must be large and powerful to grasp all the flesh of the top and back part of the thigh, otherwise your patient will lose a great deal of blood. I was wont to give an instance of the freedom of inosculation here; but I happened this morning to be in consultation with Sir Astley Cooper and Mr. Copeland: the subject was, the tying

the main artery, to suppress the growth of a tumor,—when Sir Astley gave us an instance in point. A tumor had formed upon the leg; and he had taken up the idea, that by tying the main artery of the thigh the vascularity of the tumor would be so diminished that it would fade. The operation failed to have this effect, and amputation was necessary. Amputation being performed below where the artery was tied, the blood, notwithstanding, spouted out directly from the artery, as if it had never been tied. Now that exactly corresponds with a case which I saw under the hands of Mr. Lynn, of Westminster, the first year that I came to London. The artery had been tied for aneurism; amputation became necessary, when the blood jetted out from the main artery as if no ligature had been previously placed upon it. When, then, you are operating very high in the thigh, you can, if you choose, compress the artery at the groin, but do not trust to it; either have the tourniquet, as I had, round the hip, upon the back part of the thigh, so as to compress the collateral vessels, or see that the hands and fingers of the assistant are long enough and strong enough to compress the whole limb, and more especially the arteries which come round from the back of the pelvis.

You see here a large open wound, and no blood flowing from it. This you understand to be the character of a lacerated wound. No doubt the patient had lost much blood, and therefore the force of the circulation was diminished; but yet you will observe that the moment I cut off the surface of the muscles, that moment the arteries began to bleed; and therefore it is clear that stemming of the blood was not altogether from the weakness of circulation, but from the nature of the wound. It is an instance of what I have often spoken to you of, the relation between the blood and the containing vessels, on which principally the spontaneous stopping of hæmorrhage depends.

I hope I have now drawn your attention to all the circumstances of these desperate cases of fractured limbs and lacerated muscles; as far, at least, as I am authorised by the circumstances of the present case. From the extent of railways, and the extraordinary increase of machinery, such cases will present themselves to you many times, in the active life to which you are destined. It is on this consideration that I thought it incumbent not to permit this case to escape you without comment.*

* The lad is recovering.

EXTRACTS

FROM

DR. DAVY'S ACCOUNT OF SOME

EXPERIMENTS AND OBSERVATIONS ON THE TORPEDO *.

[These extracts are inserted at the request of Dr. Williams, who is satisfied that any other reply to Dr. Wilson Philip is unnecessary.—Ed. Gaz.]

The experiments which I have detailed on the electricity of the torpedo, confirm those of Mr. Walsh made in 1772, showing its resemblance to common electricity. They moreover show that, like common electricity and voltaic electricity, it has the power of giving magnetic polarity to iron, and of producing certain chemical changes. In these its general effects, it does not seem to be essentially peculiar, but as much allied to voltaic electricity as voltaic electricity is to atmospheric, or atmospheric electricity is to that produced by contact or friction.—*Phil. Trans.* 1832, p. 272.

Mr. Faraday, in the third series of his experimental researches on electricity, states, that he has little or no doubt, were Harris's electrometer applied to the torpedo, the evolution of heat would be observed. I have made very many experiments on this subject, completely establishing Mr. Faraday's anticipation.—*Ibid*, 1834, p. 542.

This instrument was strongly affected by active fish, and even distinctly by weak ones.—*Ibid*, p. 543.

The tests or indications of the electricity of the torpedo at present known, are six in number, namely, the physiological effect, as the sensation it imparts is sometimes called; the chemical effects, as the precipitation of iodine, the decomposition of water, &c.; its effect on the thermometer, on the galvanometer, and on steel in the spiral.—*Ibid*, p. 544.

It having been stated, on high authority, that a spark has been obtained from the Gymnotus electricus†, I have thought it right to renew the attempt to procure a spark from the torpedo. I

* Phil. Trans. 1832 and 1834.

† Vide Bloch's Ichthyologie, p. 1020; and M. De Humboldt, Ann. de Chimie et de Physique, tom. xi. p. 427.

have tried the method which it is said succeeded with Mr. Walsh in the instance of the Gymnotus, namely, dividing with a penknife gold-leaf attached to glass, and connecting the divided parts with the contact wires. Using an active fish in this way, I could neither observe a spark in the dark, nor in the light detect the slightest indications of the passage of electricity, &c. Reasoning on the subject, this, perhaps, is what might be expected, considering that the surface of the fish is a better conductor than air.—*Ibid*, p. 545-6.

The electricity of the torpedo, theoretically considered, offers a wide field for speculation. Is it, it may be asked, merely a form or variety of common electricity, or a distinct kind, or not a single power, but a combination of many powers?

The first opinion, which is commonly received, and which has been ably advocated recently by Mr. Faraday, is supported by the majority of the facts contained in this paper. The circumstance principally hostile to it, at least in appearance, is the interruption of the torpedinal electricity by the smallest quantity of air, and its want of the power of attraction and repulsion in the air.

These peculiarities are seemingly in favour of the second opinion, that the electricity of the torpedo is specific and peculiar. But till the opposite surfaces of the electrical organs can be perfectly insulated, so that no easier mode of communication is afforded than through air, they can hardly be considered as deserving of much weight.—*Ibid*, p. 548.

This, for the present, is a sufficient explanation why the electricity of the torpedo does not affect the gold-leaf electrometer.—C. J. B. W.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue a abréger."—D'ALEMBERT.

Annales d'Hygiène publique et de Médecine légale. Tome XIV. Deuxième partie.

THE articles in this number are diversified and interesting. In the department of HYGIENE we have, in the first place, a translation of the paper of Dr. Casper, of Berlin, *On the Influence of Marriage on the Duration of Life*, of which we gave the substance in a paragraph in our last number (p. 591.)

The second article is on a curious as well as homely subject—the fattening of pigs: it originated in a question proposed by the French government,—

Whether the sale, slaughter, and consumption, of pork fattened with horse-flesh, were likely to be prejudicial to the public health? MM. Adelon, Huzard fils, and Parent-Duchâtelet, have decided in the negative, and their answer is in the paper before us. The circumstances which led to this investigation were briefly these:—Various localities about Paris, where knackeries and carrion butcheries were established, had for above ten years constituted a nuisance intolerable, yet irremediable, when at last the expedient was adopted on a great scale of steaming the flesh of the dead animals. This prevented putrefaction, and rendered the bones perfectly pure, and free from ill odour. Some intelligent speculators then hit on the plan of giving the boiled flesh to pigs, and it proved very successful: so much so that large herds of swine, from 400 to 500 together, are now kept and fattened in the environs of Paris; and it is said that some of them will presently be increased to the number of 1000 or 1200. The carrion is steamed on the premises in some of these porkeries; in others it is given to the pigs raw; but whether cooked or raw, the pigs thrive wonderfully on the diet, so as, in fact, to become from 15 to 18 francs a head more valuable in the course of six weeks or two months.

But the swinish multitude—the lovers of pork—soon raised an outcry against the new system; they could not stomach the idea of pig fattened with dead horse, and accordingly raised several scandalous rumours:—1. That pigs thus fed must be dangerous—perfect cannibals—eating all the children they could catch hold of. 2. That the flesh of such pigs must give rise to disorders in the human body, particularly to leprosy. And 3. That pork-butchers in certain places sold sausages made of the produce of carrion, and therefore ought not to be dealt with. The pork-butchers suffered accordingly; but the council of salubrity took the matter up, as we have just now mentioned.

Nothing can be more methodical than the proceedings of the reporters: an application is made in the first instance to M. de Blainville and M. Desmarets, the eminent zoologists, to ascertain whether the hog is naturally carnivorous. According to these gentlemen the hog ranks, by reason of his organization, between the carnivorous and the great herbivorous mammalia. Like the omnivorous animals, such as man, the bear, and the rat, his molar teeth are adapted for variety of food. The stomach of the hog, also, is membrano-muscular, without any complications or divisions like those in the stomachs of the ruminants, which are herbivorous *par excellence*. In short, the conclusion is that the hog is omnivorous, and that nature intended animal matter to form a portion of its food.

Observation also shews that swine will not fatten on mere grain or vegetable matter; on the contrary, they become pot-bellied, meagre, and measly, on such fare; while the regular addition of a little gelatine to their daily allowance has been proved by experiment to restore them to health, and to give them a proper degree of *embonpoint*.

In the Veterinary School at Alfort, there are generally kept from 100 to 150 pigs of all sorts and sizes; and for the last seven years they have been fed on nothing but the *débris* of dead horses which have been dissected. This refuse matter is thrown to them in a raw state, and they eat it greedily. Now there are no better pigs, nor better pork for eating, than are found at Alfort. The pupils eat it without scruple, and it has never had the least bad effect upon them. Nay, MM., the reporters, are highly pleased with the food—they tell us it is excellent. "*Nous avons assisté* (say they), *à un repas de cette école, et avons goûté le petit salé qu'on servait ce jour-là, et nous l'avons trouvé parfait.*" This was putting it to the pudding-test, than which we all know there is none better.

As to the assertion that this sort of food renders animals ferocious, it is not borne out by the fact. At Alfort the children of the swineherd are constantly about the pigs, pursue them, and make them readily obey the word of command; yet, though thousands of swine, fed entirely on *raw* carrion, have been reared in this establishment, not an accident has ever occurred which could be attributed to ferocity arising from that cause. It is not likely, therefore, that *boiled* flesh should infuriate them.

There is no evidence whatever of any disease (particularly leprosy) being traceable to the animal nutriment of pigs. The herd at Alfort are always healthy, as are those who feed on them.

The question of possible danger from eating of swine fed on the flesh of animals which had died of *disease*, is also negatived. Dogs and cats have been fed for some time on cancerous flesh, and they have grown fat upon it. Desgenettes and Larrey have seen the dogs and jackals at Jaffa rooting up and devouring the bodies of those dead of the plague,—eating their very buboes, without appearing to suffer the least inconvenience. In the course, also, of the first French revolution, the starving wretches of the faubourg St. Germain and the vicinity of Alfort, ate perhaps from 700 to 800 distempered and farcied horses which were sent to those places by government for purposes of experiment: yet, so far from doing mischief in any instance, the supply saved the lives of many unfortunate people.

In conclusion, both on the score of administrative economy and that of hygiène, the reporters strongly recommend the encouragement of this new branch of industry. It puts an end utterly to the disgusting business of the former carrion butchers: the flesh of dead animals is turned to a most useful purpose, and should there be a greater quantity of it than is wanted for immediate consumption, the steam process, by drying it, renders it fit for keeping and for service in various ways.

There are two other papers in the hygiène department, of which we can only give the titles. One is a very long article, by MM. Labarraque, Chevallier, and Parent-Duchatelet, *On the Means of Improving the Common Sewers of Paris* (illustrated by several engravings); and the other, *An Account of the Sick Prisoners in the Maison Centrale at Nismes*, by M. Boileau-Castelnau.

The MEDICO-LEGAL contributions are four in number:—1. On the strangulation of new-born infants with the umbilical cord, by M. Tauffliεb; 2. A report by MM. Chevallier, Orfila, and Barruel, on certain blood-spots found on clothes, &c., in connexion with an accusation of murder; 3. M. Leuret, on a case of alleged burning to death; and 4. A set of cases of homicidal monomania.

Strangulation with the Umbilical Cord.

In M. Tauffieb's paper the question is discussed, whether there is any distinctive character by which strangulation with the umbilical cord can be known? In ordinary infanticide by strangulation, medical jurists have generally asserted that there is found a livid red circle round the neck, while in accidental strangling by the navel-string this circle is wanting. But some of the most eminent modern authorities have shown that this characteristic is fallacious. Dr. Schwartz, of Fulda, has actually seen the livid furrow produced by the umbilical cord; and Wildberg, in examining an infant which had lived a quarter of an hour after birth, but had suffered severe compression by the cord in the delivery, found that there was still present a narrow red circle round the neck, though without depression or ecchymosis. Carus, also, met with a similar case. And the result of these several observations is, that the marks of accidental strangulation by the navel-string are not to be distinguished from those produced by any other cord applied with a criminal intention.

M. Tauffieb, however, suggests that there are two circumstances which may guide us in our medico-legal diagnosis. In the first place, when there has been strangulation by the umbilical cord, the placenta may generally be expected to be found expelled along with the child; and secondly, there will be detected no indications of respiration having commenced; of course, none of the signs of death by asphyxia. Any exception to this, as in Wildberg's case above-cited, must be looked upon as exceedingly rare.

Analysis of Blood-spots.

There is nothing very important in the report of MM. Chevallier, Orfila, and Barruel, at least of a positive kind: the results were principally negative. The questions proposed by the legal functionaries were complicated and difficult, not generally admitting affirmative answers. A gamekeeper had been murdered, and certain persons were in custody charged with the crime. Spots were found on the garments of all the parties, and it was sought to determine whether these were blood-spots—whether they were of human blood, or that of a sheep or hare, or the like; also, of what date were these spots—whether they were of some weeks or some months standing; in short, whether the traces of blood on the victim corresponded with those on the alleged murderers. The medico-legal examiners were able to show that most of the spots were of blood, and probably of human blood; but they could determine little more with any degree of probability.

Burns, before or after Death.

In M. Leuret's paper on distinguishing burns as inflicted before or after death, there are some very important points; particularly where allusion is made to Dr. Christison's experiments and observations on the same subject.

The case which forms the staple of the article, is given at considerable length from the *Gazette des Tribunaux*. The following seem to be the principal particulars:—

On the 10th of July, 1834, the woman Berenger was found dead in her sleeping apartment. Her body, which was quite naked, was found on the hearth, with the head in the fire-place. Both head and neck were burnt to *carbonisation*. The medical man called in to examine the remains thought it possible that murder had previously been committed by strangulation, and that the burning was but an expedient to hide the proofs of murder. The circumstances of the woman and her husband made it not improbable that the latter committed the crime. On the night of the 5th July, cries like the howling of a dog were heard issuing from Berenger's house. Berenger himself, on the following day, appeared at the door of his wife's chamber, demanding admittance; and on not receiving any answer to his repeated knocks, he was heard to use the expression, "that he feared all was not right." He then pushed in the door, hastily threw himself on the floor beside the body, and said, "Ah! I knew it—I thought it would come to this—she is burnt to a cinder." The man was arrested; and M. Seguy, the medical witness above-mentioned, made his formal report. It was to the effect, that he found Madame Berenger lying on her left side, with her head in the middle of the fire-place. The legs were in an easy state of flexion, and neither hands nor feet betokened struggling. Beneath the body were some remains of a chemise, which had evidently been consumed by fire. The habit of body

was spare and delicate: the limbs possessed considerable cadaveric stiffness. None of the parts of the face could be recognized, they were so completely burnt. The hair of the head was all burnt off, except what belonged to the left temple, where it was copiously matted with blood, not yet quite dry. The burnt parts were no where encircled with redness; nor were there vesicles observed, except on the lower part of the abdomen and on the left knee. On opening the head there was found to be strong adhesion of the membranes to the cranium on the left side; those on the other side were strongly injected; the sinuses were filled with black blood, and the substance of the left lobe of the brain was reduced to *bouillie* about the temporal region and base of the skull. The ventricles of the brain contained a bloody serum. The lungs were hepatized, gorged with blood, and the bronchia were filled with a reddish mucosity. Such were the chief appearances. M. Seguy infers from them apoplexy (!) *caused by violence*, and producing death previous to the burning. That it was not an *accidental* apoplexy he concludes from the habit of body of deceased, and from her history: but, on the whole, the examiner declines saying any thing positive.

Another medical authority was brought forward by the friends of the accused, who contradicted or neutralized most of M. Seguy's report. We shall only extract what the new referee says regarding the appearance of the burns:— "The absence of vesicles and circles of redness in the upper parts of the body is owing to the continuance of the process of burning. The traces of their appearance on the lower parts show that the fire commenced at the bottom of the chemise; by which accident the apoplexy was probably caused, and the consequent fall on the hearth. In conclusion the reporter states, that, in his opinion, the woman Berenger was not strangled, but died of sudden apoplexy." Notwithstanding this, the husband Berenger was condemned to hard labour for ten years.

We have not room to give the observations of M. Leuret on this curious case—with the result of which he appears dissatisfied; but we must not omit what he says in the way of qualifying Christison's diagnostic remarks:— "The experiments of Christison show that vesicles filled with serum were not formed after death in those subjects on which he tried to raise them; but this does not prove that they may not be formed in subjects placed in different circumstances. I have seen large and numerous vesicles filled with serum raised on a dead body, at least twenty-four hours after death. It happened in this manner: I had placed a brasier, full of burning charcoal, near the legs of an infiltrated subject (*cadavre infiltré*); the epidermis hardened a little, then rose, and underneath was found an abundant collection of a reddish serosity. On removing the brasier to other parts of the body the same phenomenon was observed. I have since tried the experiment on various subjects not infiltrated, but have not succeeded in producing the same effect."

MEDICAL GAZETTE.

Saturday, January 16, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri: potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

A WORD OR TWO ON THE NEW UNIVERSITY.

It is very amusing to watch the antics played by the *one-faculty* men on the eve of the establishment of a Metropolitan University. They have gone through various tricks of ground and lofty tumbling, but seem to have so addled their brains by the performance, that they know not whether they stand on their heels or their heads. First we had the announcement of a grand spectacle (this was some time ago), called the "OneFaculty-*instar omnium*," which was to embrace a multitude of *dramatis personæ*, and to be the most splendid thing the world ever saw. But it went lamely off, and was soon shelved. Next came what was expected to be a more popular entertainment, under the imposing title of "The Tri-partite Faculty," the performers to be selected from among the stars of the three kingdoms; and the prime attraction, the display of an educational chimera or cerberus—a sort of

"three gentlemen at once," its uppermost part fire and smoke, &c.—but it all turned to smoke, and vanished in thin air. What was the next expedient of our "managers in distress"? They found the public taste strongly in favour of something more like the *legitimate* drama than the non-descripts hitherto offered them, and a rival House having got up with considerable pains a new piece, to be called the "University of London," and which is still in preparation,—our rival managers, at their wits' end, are endeavouring to bring out the same thing with the addition of various crackers, rockets, and explosions, which they feel assured will quite captivate the genuine lovers of noise and confusion.

But in sad and sober earnest, we cannot but commiserate our speculating and evidently much disappointed contemporaries; they find themselves reduced to a very awkward pass. After all their high-flown promises and anticipations, they are obliged to settle down to the contemplation of a simple University in London for giving degrees—those degrees, too, to be granted as nearly as possible on the same terms as are required in other Universities, with this special exception, that here there shall be no religious tests. What a falling off for those who had calculated on, and assured the world of, the downfal and utter destruction of all the medical institutions in the empire, in order to make room for One Faculty! Poor creatures, we can well understand how much they are beside themselves: they must be restrained from doing mischief in their madness, however.

The occupation at present of the parties referred to is to endeavour if possible to pull the scheme of the new University to pieces. But they must have a shrewd guess that their destructive efforts will be of no avail. They affect to be intimately acquainted with the details of the new structure, while, in reality, they know nothing about them. Failing in their endeavours at demolition, their next resource is to suggest alterations and improvements. Let us see what some of these are.

It seems to be the notion of our *ci-devant* "one-faculty" people, that the "University of London" ought to be put upon a footing different from that of any other similar establishment in Europe: it ought to be thrown open, they say, for the benefit of certain individuals of a poorer grade, so that every one who deems himself competent for obtaining a degree shall be allowed to present himself for examination: there should be no test of a regular education required, but the examiners should determine in the first and last resort on the sufficiency of the candidate. What a pitiable ignorance does all this exhibit of the object and working of a University! But what else can be expected of the parties? They are not aware that this sagacious proposition has been again and again canvassed, in the formation of educational establishments like the one in question, and invariably rejected for its impracticableness. The progress of society cries aloud against it, and most especially the progress made in this country and in this metropolis. In a small community, where every member is under the immediate eye of the superintending authorities, it might be possible to establish a board to grant diplomas to parties offering no other qualification than the mere passing of an examination; but in the metropolis of Great Britain, what senate, or board of examiners, would take upon themselves the responsibility—the onus—of ascertaining the claims to degrees of all adventurers who should happen to come before them? To do this with any possibility of satisfaction to themselves and the public, they must not be

left without the protection of some preceding test—some ground for admitting candidates to the final scrutiny; and every reasonable man must admit that there is no test so proper for the purpose as that of showing that the parties have been educated after an approved and recognized system.

Our worthy speculators say that this is to secure a monopoly in favour of two or three schools—such as London University College, King's College, &c. They may spare themselves the uneasiness of this notion. There will be, in this respect at least, no monopoly recognized. All the respectable schools of the metropolis will stand upon a fair footing; or rather, none will be denied the privilege of preparing candidates for the University Board, which have due means and appliances of bestowing a proper medical education. This liberal allowance, however, must not be understood to apply to those rubbishing concerns where two or three ill-authorized individuals, gathering into some obscure corner, and professing to teach three branches each, deceive the public with the semblance of a medical school. If it be a monopoly to exclude things of this sort, then we are sure there will be a monopoly —but one which we think no respectable member of society will grumble at.

Here, however, we should not omit to notice what some, who appear to be well informed, have stated rather confidently—namely, that it is in contemplation to make a degree in arts a prerequisite for a degree in medicine; and not only so, but that the said degree in arts should be taken in this metropolis, or in one of the other English Universities. We discredit the rumour, but must say, that if such plan were adopted, we should protest against it in the strongest manner. Monopoly, and that of a most obnoxious kind, would be thus stamped upon the front of the new institution. For with what reason (if a degree in arts ought to be at all insisted on) should those taken elsewhere than in London, or in England, be excluded? Surely those obtained in regular Universities in other parts of the United Kingdom, or on the Continent, provided actual residence be required, ought to be equally acceptable as a test of the requisite preliminary education.

Another important question, in the settlement of which we must all feel an interest, is—who are to be the members of the University senate; and in particular, who are to constitute the Board of Examiners? Our enlightened but restless speculators, who would have this a *National* institution (in the true revolutionary sense of the term) propose, of course, that it should be decided by *concours*. They may spare their disquietude on this head also. The appointments will be made in due time, and we trust in a satisfactory manner. One word, in conclusion, to a mortified legislator — an *honourable* man — who tells us it is a "report," but a "falsehood," that certain parties whom he names have been called into the councils of the Chancellor of the Exchequer, to lend their aid in the formation of the new establishment. We can inform him, that however current the "report" may be, and however unpalatable to him and his dupes, it is *not* "a falsehood." We do not pretend to state the particulars of what is in progress, but the *on dit* is probably not so much at fault. We merely allude to it to warn people how they listen to "falsehood" as denounced by the enemies of truth.

MEDICAL GRIEVANCES UNDER THE POOR-LAW.

Ruricola's letter, at page 619, will be found to contain a clear and comprehensive plan for remedying the present annoyances suffered by medical practi-

tioners, in consequence of the working of the amended Poor-Law. We strongly recommend this valuable document to the immediate notice of the profession at large, as containing what appears to us the most practical and efficient scheme of relief yet proposed in any quarter.

CLINICAL LECTURE

ON

A CASE OF COMPOUND FRACTURE OF THE TIBIA,

FOLLOWED BY TRAUMATIC DELIRIUM:

Delivered at St. George's Hospital, Dec. 22, 1835,

BY SIR BENJAMIN C. BRODIE, Bart.

GENTLEMEN,—I shall begin with reading the notes of a case to which I purpose to call your attention in this day's lecture.

"George Reeves, æt. 50, by occupation a coal-heaver, was admitted on the 7th December, 1835, into Oxford Ward. He had a compound fracture of the right tibia, about four inches above the ankle. The wound was small, the bone not protruded, nor the apparent injury in any way very considerable. The accident had been caused by a heavy piece of stone falling from a considerable height upon the limb. Some hours elapsed before he recovered from the shock of the accident—that is, from the state of collapse which it occasioned. The limb was placed on a pillow, with junks and a splint on either side. He was directed to take forty drops of laudanum. On inquiry, it appeared that the patient had been in the habit of taking a large quantity both of porter and gin. On that account it was directed that he should be allowed a pint of porter daily, from the time of his admission into the hospital."

The report on the 9th December, two days after his admission, is as follows:—"He slept little during the night: the pulse was frequent, but not strong. When he held up his hand, it was observed to be very unsteady — quite tremulous. His tongue was white, and, when he put it out, that was tremulous also. He was directed to take four ounces of gin daily, in addition to the porter."

The next report is on the 11th December; and it is then stated, that "for the two preceding nights he had been much excited and hurried in his manner, having had little or no sleep. The leg was examined; there was no more inflammation than there ought to be about the wound. In was placed in an Assalini's fracture box. He was directed to take a grain of acetate of morphia, with some compound extract of colocynth in the evening."

"On the evening of the 12th he became delirious, and was quite unmanageable, so that it was necessary to confine him in a straight jacket. On the morning of the 13th he got some sleep, but not until he had taken as much as two drachms of laudanum. When he awoke from this sleep he was talking incessantly. There was much trembling of the hands; the pulse very frequent, but not strong. However, he answered questions that were put to him rationally. I prescribed for him the following draught:—One ounce and a half of camphor mixture; a quarter of a grain of acetate of morphia; a drachm of oxymel, and a drachm of comp. spir. of sulphuric æther: to be taken every six hours. He was directed also to have allowed him two pints of porter and six ounces of gin daily."

On the following day (the 14th), "he was much better; the pulse was less frequent, and there was less trembling of the limbs. He had some comfortable sleep during the night, and was quite collected on awaking in the morning."

On the 16th, it appears that "he had had no return of the delirium, but that he talked a great deal at times, and in a very hurried manner. The pulse was reduced to 90 in a minute; the tongue continued white."

"On the 17th he had again become violently delirious during the night, so as to require the straight waistcoat. He took ten grains of camphor and two grains of opium, which produced a comfortable sleep, and he was now better. The pulse had risen to 110, but it was not a strong pulse, like that from inflammatory disease. The tongue was white, and brown in the centre; the bowels were open. He complained of shooting pains in the leg, but on examining it there were no marks of unusual inflammation in it; in fact the leg had been going on well during the whole of this time. He was directed to continue the same draught, taking half a grain of acetate of morphia in each draught, instead of a quarter of a grain."

On the 21st (that is, yesterday), "he was perfectly rational during the day. He had slept a good deal, but during the preceding night he had been very restless, and it had been necessary to secure him once more by the straight waistcoat. There was still some trembling of the hands. The pulse had fallen to 80, the bowels were opened regularly without medicine, and the tongue had become clean. The leg was doing perfectly well. He took the whole of his porter, gin, and medicine, regularly, and also some light nourishment. During the whole course of these symptoms he

had not been denied nourishment, but he had not had much inclination for it."

You will observe that on the 17th there had been some aggravation of the symptoms. He had been put into a ward by himself, in order that he might not disturb the other patients. His wife was with him, and there was some reason to suspect that she partook of the gin and porter allowed him; and if so, we may account for the symptoms having been then aggravated, by the circumstance of his not having had the quantity of stimulus that he ought to have had.

Here is a man, then, who meets with a compound fracture, but not a very bad one. The local injury has been going on very well, but he has been, from a short time after he came into the hospital, in a state of delirium approaching to mania in its character; and he has been getting better, not under the use of the lancet and other antiphlogistic remedies, but by stimulating him with gin and porter, and giving him opium. Here is a disturbed state of the nervous system, following a slight local injury, and not depending on inflammatory action any where.

Many cases occur in which symptoms somewhat corresponding to these follow a local injury. We say that the patient labours under *traumatic delirium*, under delirium supervening on a wound: perhaps *mania* would be the more proper appellation; for the symptoms more resemble those of mania than of the delirium of fever.

These maniacal symptoms after injuries no doubt depend partly upon the injury inflicted; but they depend more on a peculiar condition of the nervous system of the patient. The nervous system of one man is in that state that no local injury will produce these symptoms; while, in another, they are produced even by a slight accident. Various circumstances make the nervous system thus differently susceptible in different individuals. In the museum you will see a preparation of the lower extremity of the tibia, in which there has been an abscess. It was taken from the leg of a gentleman, which I formerly amputated; and it was the first case that made me understand the nature of those abscesses in the centre of the tibia, and which, since, I have been enabled in three cases to relieve by the application of the trephine; thus preserving the patient's life and limb also. In this case, neither myself nor any one else who saw the patient, understood at the time the nature of the disease. There had been an abscess in the centre of the tibia, pent up in unyielding bone; and, being thus pent up, it was the cause of an unusual quantity of pain and distress. He had been going on thus for fourteen or fifteen years, and his nervous system was, in consequence, in a state of excessive irritability. He had not any bad habits as to his mode of life, but his mind and body suffered from the effects produced by the constant torment of an abscess locked up in the centre of the tibia. He bore the operation of amputation without saying a word, but in the evening he was restless and uncomfortable, talking incessantly. There was some secondary hæmorrhage, which rendered it necessary to take the dressings off the stump; and though he had been quite tranquil at and after the operation, yet, when the dressings were removed afterwards, he roared so that he could be heard in the street when the dressings were removed. During that night he slept not at all; the next day he had a rapid pulse, was talking incessantly, and the tongue was quite clean. The pulse continued rapid, and the tongue quite clean. Night after night he procured no sleep; he talked incessantly night and day, believing that there were individuals in the room who were not there. On the fifth day, his tongue, for the first time, was covered with brown fur; the pulse was so rapid that it could not be counted; he was in a state of great prostration of strength; the retina of the eye became perfectly insensible; the pupils were widely dilated, and when a candle was put close to the eye he was not sensible of the light, and the pupil did not contract in the smallest degree. This insensibility of the organs of vision was followed by a general stupor, in which he died. No morbid appearances were found in the *post mortem* examination. In this case, the maniacal symptoms following the injury, and which terminated in the patient's death, evidently arose out of a disordered state of the nervous system, which might itself be traced to the impression made on it for a great number of years by a very painful local disease.

But to what are the peculiar nervous symptoms that have taken place in the individual now under treatment to be attributed? You see such cases not unfrequently in the hospital. They occur chiefly in persons who have been accustomed to drink a great deal of fermented liquors and ardent spirits. An individual who has these bad habits meets with an accident; he comes into the hospital, and is kept on low diet, and in the course of the following day you find the following symptoms begin to show themselves:—At first, as in this patient, you recognize the disease by there being rather a hurried manner, by the patient's hand being tremulous; then his manner becomes more hur-

ried, the hand more tremulous: he is never quiet, but is in a state of constant gesticulation, and incessantly talking. He answers questions which you put to him, and is sensible to external impressions; yet he is talking of things that do not exist, believing that people are present who are absent, or that he is employed in something in which he cannot, under the circumstances, be employed at all. He sleeps little, or more frequently not at all, and the pulse becomes rapid. The tongue sometimes remains clean, and at other times becomes furred. Although the pulse be rapid, it is not a strong, hard pulse; on the contrary, it is generally weak, so that you would say that if the patient were to be bled he would sink. If nothing be done for the patient's relief these symptoms may go till the fourth or fifth day, or longer; and then he may become exhausted, sink, and die. In some cases other symptoms supervene,—sickness, vomiting, diarrhœa, and a constant discharge of watery evacuations from the bowels.

In the *post mortem* examination, if the patient die at an early period, you may perhaps not be able to find any morbid appearances whatever; but if the disease has been protracted, you discover some effusion among the membranes of the brain; and it is said that sometimes there is ulceration of the small intestines. From whatever cause these maniacal symptoms which follow local injury arise, they do not depend on any inflammatory action of the brain or its membranes, or inflammatory affection of any other part. They are not to be relieved by depletion, and what is commonly called the antiphlogistic treatment: on the contrary, they are aggravated by bleeding, and by all other depleting measures. They indicate an absence of power, and are to be relieved not by the abstraction, but by the exhibition of stimuli. In illustration of this observation I may tell you what I have sometimes known to happen after injuries of the head. A gentleman, for example, was thrown from a carriage, and struck his head. He laboured under symptoms which, as I was led to believe, indicated a severe concussion of the brain, complicated with a slight degree of extravasation. These were followed by other well marked symptoms of acute phrenitis. He was bled; and the coagulum was much contracted, cupped on the surface, and covered with a thick buff. He was bled again, and so on, till the symptoms were relieved. But now he became maniacal, and got into the same state in which this patient was the other day. He could not sleep; he was in a state of continual jactitation, talking incessantly, believing he was driving his carriage or riding on horseback, and knowing nothing of the persons about him. Bleeding was again had recourse to, but was followed by an aggravation of the symptoms. Another practitioner was called in, and advised that he should be still further bled; and this was done in opposition to my judgment: but the patient was still worse afterwards, so that he seemed to be on the point of death. I then turned round, and gave him wine and nourishment; and the moment that the stimulus entered his circulation, the maniacal symptoms began to subside, and in the course of a very short time he was perfectly well.

There are two periods, then, after an accident, at which maniacal symptoms may occur. They may occur in certain constitutions immediately after the accident has happened; and where the nervous system is less susceptible, they may occur at a later period, when the patient has been lowered by repeated bleeding and purging, and that constant starving which severe local injury will sometimes require.

The cases in which we see these symptoms occur in the hospital are, as I have mentioned, chiefly those of drunkards, or at any rate of people very much accustomed to the stimulus of fermented and spirituous liquors. They take place so continually in persons of this class, that I generally direct that the habits of patients admitted with accidents should be inquired into; and, if they have been downright gin-drinkers (except, indeed, there be some strong reason against it), that they should be allowed a certain quantity of porter or gin from the beginning. In this case Mr. Robinson, the house surgeon, very properly made this inquiry, and the patient was allowed porter in the first instance; but you perceive that the quantity was not sufficient. Then, two days afterwards, I allowed him a certain quantity of gin; still that was not sufficient, and I found it necessary to allow him a larger quantity afterwards; and even this would not have been enough, if we had not combined other means with it. And what were those other means? Opium and Hoffman's anodyne; that is, the comp. spir. of sulphuric æther. The patient took at first a quarter of a grain of morphia, and then half a grain every six hours, with a drachm of Hoffman's anodyne; and this was attended with very beneficial results. Opium is productive of very good effects in these cases; you cannot depend solely on the exhibition of spirits and fermented liquors, and it is prudent to combine opium with them. The patient will bear a large quantity of opium here, such as would almost poison him in a state of health. Even the full doses which I ordered for this patient

every six hours were not sufficient; and he was forced to take a couple of grains of opium once or twice in addition; and although I said that the draught was given every six hours, yet he took an extra draught occasionally besides. It is curious to observe in these cases, how immediately, for the most part, the symptoms alter when the patient is put under the influence of alcohol and opium. This was very manifest throughout the whole of this man's case; and there is great reason to apprehend that the aggravation which occurred one day arose, as I mentioned, from his not getting the whole of the stimulus that has been prescribed for him.

This disease bears a near relation to some of those cases which have been described under the name of *delirium tremens*, but not to others. It has been well observed, (I believe by Dr. Stokes) that under that term writers have sometimes confounded together different maladies. In some cases, where the patient has been said to labour under delirium tremens, the maniacal symptoms have been the consequence of excessive drinking for some days. A man unaccustomed, perhaps, to drink a great deal of liquor, indulges himself in this manner for some days in succession; and at last he gets wrought up to a state of mania, from which he is to be relieved, not by giving him more stimulus, but by gradually, and prudently, and carefully, diminishing the quantity of stimulus which he has been lately taking. Then, in other cases of delirium tremens, the symptoms have been the consequence, not of the continued use of stimulants, but of their sudden abstraction; and it is to this last class that the case of this man properly belongs. There is no doubt that the symptoms depend chiefly upon the peculiar condition of the patient's nervous system: but that is not all; for if this individual had been admitted into the hospital, not suffering from a mechanical injury, but with an ulcer of the leg, it is not probable that these symptoms would have come on. They may develope themselves, and sometimes do, without mechanical injury, but still there is no doubt that the slightest impression made on the nervous system in this manner makes the patient much more susceptible of these symptoms than he would be otherwise.

The theme of medicine is ever the same, only the melody alters. And later times have been so prolific of composers, that every couple of years we sing a new song.—Hufeland.

LECTURES

ON THE

DISEASES OF THE NERVOUS SYSTEM.

By M. Andral.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

INFLAMMATION OF THE SPINAL MARROW.

[We subjoin the conclusion of M. Andral's inquiry into the connexion between the cerebral lesion and the paralysis, as the subject was begun last week. We shall, however, be compelled, by press of other matter, to postpone the rest of the lecture till this day fortnight.]

The third case is to be found in the work of Morgagni, who relates it on the authority of others. An individual, 70 years of age, was suddenly attacked with apoplexy, accompanied by hemiplegia of the right side: blood was found in both ventricles, with some erosion of the right optic thalamus. This case is unsatisfactory, and does not bear the stamp of Morgagni's accuracy. It is said that the effusion existed in both ventricles; but might it not have been more considerable in the left? On reading the case, it is seen to be defective.

The fourth case belongs to Brumer; it is to be found in the third part of the Journal of the Curiosities of Nature. A woman, 47 years of age, fell down in an apoplectic fit, in whom paralysis was observed on the right side. Several apoplectic cysts, which Brumer carefully describes, were found in the right hemisphere. The first attack had taken place four years before death; some recent clots, which had been the immediate cause of the last attack, were found beside the old cysts.

The fifth case was seen by Morgagni, who relates it in his 57th letter. An old woman died, having paralysis of the right side; and on examination, softening of the brain was found, also situated on the right side. Here Morgagni relates what he saw himself; he is not content with merely stating what lesion he found, but he proceeds to describe the state of the rest of the brain, on the left side of which he found no morbid change whatever.

The sixth is recorded in the 13th letter of the same author. This instance occurred in a woman, aged 24, who had apoplexy, with paralysis of the right side; she died, and a coagulum was found in the midst of, and without, the right corpus striatum. Morgagni did not trust to his pupils, by whom the case was related; he went to see it himself; and it was

only after he had become thoroughly satisfied, that he gave it a place in his work, expressing the astonishment which it had excited.

The cases which follow are modern.

The seventh was observed by M. Bayle, and was published in the Revue Médicale in 1824. There was paralysis of the left side; and on examination after death it was ascertained that the only lesion consisted in softening of the anterior part of the left hemisphere.

The eighth case is to be found in the work of M. Rostan on Softening of the Brain. The woman who formed the subject of it was 84 years of age, and had hemiplegia of the right side. On opening the body, an old effusion, with softening, was found at the lower and back part of the right hemisphere.

The ninth case is given by M. Leuret, in the Journal de Progrès. Here the case is less clear than with regard to the others. It relates to an individual who had paralysis and contraction of the right arm, and no loss of power in the limbs of the left side. But what renders the question complicated is, that both hemispheres were diseased, although the right was the one principally affected, there having been but a very small portion of softening on the left side.

The tenth case, that by Winmeyer, relates to a man who had palsy of the left side, in whose brain, according to the author, was found an old cyst at the anterior part of the left lobe; but the hemiplegia was recent, and we cannot tell whether sufficient examination was made to ascertain the cause of the loss of power; in fact, the case is incomplete.

The eleventh and twelfth are to be found in the notes added by M. Blandin to his edition of Bichat. He relates that two men, of advanced age, died at the Bicêtre, having paralysis of one side of the body; and that in both the examination after death showed an effusion in the posterior lobe of the hemisphere on the same side as the paralysis. It is of importance to mark the seat of the effusion, because, with regard to the posterior lobe, the anatomical explanation of direct paralysis would be easy in the eyes of some, who hold that this lobe receives its fibres from a part of the spinal cord where crossing does not occur.

The thirteenth case has not yet been published; it was seen by M. Cruveilhier about two months ago. The paralysis existed on the same side as the disease of the brain.

The fourteenth and fifteenth are due to M. Duhambre, who met with them at the Salpêtrière. These two examples, which are well related, were softenings of the brain on the right side, with paralysis of corresponding limbs.

Finally, the sixteenth case of this kind has been presented by M. Fournet to the Anatomical Society, and has not yet been published.

I have never hitherto met with any thing analogous, but I admit the accuracy of some of those which have been published—which, indeed, is above suspicion. For these anomalies there must be some principle—some reason—although the explanation has hitherto escaped us. Unquestionably it is to be found in anatomy. We must, then, here lay down the principle, that paralysis may occur on the same side as the lesion of the brain.

Generally palsy affects both limbs at once, and may be either equal or of different degrees. For the most part, the paralysis of the lower limb is less complete, and less obstinate, than that of the arm. But one limb only may be affected with palsy; and then it is a question whether the anatomical lesion has a special seat in such cases. Some authors have thought it had; and this has formed the subject of various works by MM. Serres, Foville, Pinel-Grandchamp, Bouillaud, Rostan, &c.

Let us examine the question in detail. Has the hæmorrhage a different seat in cases of hemiplegia when the paralysis affects the upper, from what it has when it affects the lower limb? Some authors have laid it down as a principle, that the movements of the lower limbs are under the influence of the corpora striata and cerebral substance immediately adjoining; but that the motion of the arms derives its impulse from the optic thalami and parts surrounding them. Others, again, think that the anterior parts of the brain generally preside over the motions of the lower limbs, and the posterior parts over those of the upper limbs.

In the fifth volume of my *Clinique*, I have given an analysis of 75 cases in which the effusion was very limited: 1st, in 40 cases with hemiplegia, the lesion was found in 21 instances to be limited to the corpora striata, or extending into the cerebral substance anterior to them; in the other 19 the lesion was confined to the optic thalamus, or extended to the pulp immediately behind it. The inference, then, from these 40 cases is, that lesions of the corpora striata and optic thalami influence the movements of the upper and lower extremities indiscriminately. In 23 cases there was only paralysis of one upper extremity. Now, if the theory be true, the hæmorrhage ought to have taken place only at the posterior part of the hemispheres; but such was not the case. In

two the lesion existed in the middle lobe of the brain; in eleven the anterior part alone was affected,—a result just the reverse of what the theory would promise; finally, in the ten last cases of this second list, the effusion had taken place into or behind the optic thalamus: and experience thus gives about the same number of cases for and against the opinion of which I speak.

There were twelve cases of the 75 alluded to in which the lower limb alone was the seat of paralysis; and in all, except two, the hæmorrhage had taken place into the anterior lobe, or into the optic thalamus. Here the theory derives more support from facts, which, however, does not prevent the truth of it from being but relative; for to destroy the law, it requires only the two cases in which, with the same paralytic affection, the lesion was found in the posterior lobe.

The general consequence to be derived from these facts is, that although assuredly the same parts of the brain are not employed to regulate the movements of the upper and lower extremity, since the functions of the one may remain entire, those of the other being impaired or abolished, yet, in the present state of science, it is not possible to say what portion it is of the cerebral mass which commands the motions of the different parts of the body. The results, up to this time, are altogether negative; but they have this degree of usefulness—that they prevent us from falling into error. Does the power of motion become affected if the convolutions alone are implicated? M. Favre, in his Thesis, in 1832, gives an instance of an individual who died hemiplegic, and in whom, on examination, a small clot was found in one of the convolutions of the external lateral and rather posterior part of the left hemisphere, there being absolutely nothing elsewhere. As to the rest, this case is not unique, as M. Lallemand gives an analogous instance in his first letter, page 63, and two others in his second letter, pages 106, 151.

Cases have occurred in which there has been paralysis with the lesion limited to the convolutions of the brain. I have some cases of this kind, and all these facts constitute a powerful objection against the opinion of those who hold that the central white substance is the seat of motion.

When the lesion of the convolutions is chronic, and exactly limited to the grey substance, paralysis may be absent; from which it seems possible to maintain, that if paralysis occurs when such lesion is acute, it has depended upon the central parts of the brain having been irritated. It must be remarked, however, that in the case of M. Favre the disease was chronic.

So much with regard to paralysis in its connexion with lesion of the hemispheres; but these last may remain completely healthy, and palsy take place nevertheless.

With regard to the mesocephalon, it may be laid down as a general principle, that in hæmorrhage of this part the four limbs are paralyzed; but as in our science there are always unlucky exceptions, so in the lesion of which I speak simple hemiplegia has been sometimes observed. Anatomy can explain these anomalies: they take place when the effusion is on one side only of the mesocephalon; but such cases are extremely rare.

WESTMINSTER HOSPITAL.

REMOVAL OF THE BONES OF THE FACE.

Extract from a Clinical Lecture, delivered January 9th,

By Mr. Guthrie.

I am grieved, gentlemen, to be obliged to inform you that the case of Mrs. Brown will not turn out successfully. The removal of so many bones of the face, and of every part which appeared to be diseased, did not suffice to eradicate the mischief. I am afraid it has been reproduced from that part on the body of the sphenoid bone which occupied so much of our attention, and took up so much of our time, during the operation. I wish now I had applied to this the muriate of antimony, or the strong nitric acid. It might have done harm, but it might also have been useful, even if exfoliation of the bone had followed. It is a point to be borne in recollection for future occasions. The tumor is now advancing by the orbit, the periosteum of which seems to be engaged in it, and the external covering of the frontal bone, on its outer part, is equally implicated. The eyeball has suppurated. The tumor can also be felt behind the skin, covering the part from whence the bones were removed, but there is no projection there, as before the operation. I have only to regret that it was not done earlier, and that I had not seen her sooner; for if the disease had been confined to the superior maxillary bone, I feel very confident that success would have followed the operation. We want records of the termination of these cases after operation, undertaken at all periods of time, in order to enable us to form a correct judgment on the subject. I regret I should have to record an unfortunate one.

[Mr. Guthrie then proceeded to give an interesting lecture on Medullary Sarcoma of the Testes; which we shall take an early opportunity of laying before our readers.]

REMEDY
FOR THE
EVILS OF THE PRESENT SYSTEM OF MEDICAL ATTENDANCE
UNDER THE NEW POOR LAW.

To the Editor of the Medical Gazette.

SIR,

THE able and high-spirited letter from Mr. Barber, of Cambridge, in your last Gazette, deserves the especial notice and thanks of his medical brethren; and it is with some reluctance that I feel compelled to differ with him as to the measures which ought to be adopted on the present occasion.

However little "versed in the art of legislation" the members of our profession may be, I fear that, unless they exert themselves to devise an unobjectionable plan for medical relief to the poor—one not merely suited to their own views and interests, but calculated to obtain the support of the legislature and the landed proprietors of the country—no real and well-founded amendment of the present system can take place. It will be useless for us to apply to parliament, with a statement of our complaints, unless we are able, with some degree of unanimity and decision, to propose a rational and practicable alteration. Mr. Barber suggests "that the Commissioners should, as a general rule, desist from interfering with existing contracts." But can it be supposed that the Commissioners would desist from exercising their legal authority?—and even could this be so arranged, the power of oppression and injury would only be transferred from the *major* to the *minor* authorities; for does Mr. Barber believe that the Boards of Guardians would "continue the contracts as they were found?" Does he suppose that a "fair and open competition" can exist before a tribunal of rate-payers, where the amount of stipend must *naturally* be the criterion, and not the fitness or previous claims of the candidates? It would give me sincere pleasure to be assured that this matter might be safely left "in the hands of the local authorities;" but the contrary is evident to every close observer of the administration of the Poor-Law.

The gauntlet is thrown down by our opponents, and unless we unflinchingly take it up, and proceed to a thorough settlement of the question, the opportunity for so doing may not again occur. Were it possible to behold, without dismay, the perpetration of such inhumanity and injustice as the proceedings of the Commissioners and Boards of Guardians evince, I would rejoice that matters are now brought to a crisis, and that abuses which, under the former system, might have crept on for years without any mitigation, may now, by vigorous and honest treatment, be finally removed.

Considering it the duty of every member of our body to lend his aid, however feeble, in this cause, I propose, with your permission, to enter more fully into the details of a scheme for parochial medical attendance; the principles of which I have already submitted to you in the Gazettes of November 14th and 21st last.

At the risk of incurring the charge of tautology, or repetition, I will thus briefly sum up the evils to be remedied:—

1st. The appointment of medical officers by "tender;" which, as a *test* of the qualification of the candidates for office, is *worthless*, if not *vicious*.

2dly. The arbitrary method of "fixing on a rate of remuneration admitted on all hands to be totally inadequate, and compelling acquiescence by a threat (in many instances carried into execution*)," of invading the private practices of settled practitioners.

3dly. The supply of an insufficient number of medical attendants to the poor, causing *monopolies* of numerous parishes, and increasing the distance between the surgeons and many of their pauper patients.

4thly. The absurd distribution of parishes into certain medical districts, determined not by the comfort and safety of the poor, nor by the convenience of medical men, nor by the established usage of parishes, but by the *circuits of the relieving officers*; which are often designedly and avowedly incompatible with a ready access to relief.

5. The dangerous power vested in the relieving officers, and other non-medical persons (all of them interested in refusing orders) of deciding whether the sick pauper requires medical assistance.

6. The insulting and tyrannical treatment of the medical body by the functionaries of the Poor Law; respectable men being thereby often deterred from offering their services, and the poor being therefore left to practitioners of another description.

Any plan of amendment which provides for the removal of all these evils is worthy of the attention of the medical profession and the public. I would therefore recommend that a certain and uniform mode of parochial medical remuneration be enforced throughout the country, calculated separately for each parish, on the following principles:—the amount of sickness,

* Vide Mr. Barber's Letter.

and proportion of pauperism in the population of each parish; the superficial extent of large parishes, and the distance of small ones from the medical officer: a mode of payment, consequently, providing for all these particulars, and for a fair, though of course a low, remuneration for the cost and trouble bestowed, would answer the desired end.

Medical practitioners generally, I believe, like the idea of a salary according to the population, or according to the number of paupers, sick and well; the former is the plan of Mr. Smith, of Southam; the latter that of Mr. Yeatman, of Frome. They are both, however, in my opinion, inapplicable and deficient. Mr. Smith's does not provide for the proportion or variation of pauperism in a parish; nor does it meet properly the distance and extent of parishes. Mr. Yeatman's does not provide for the amount of sickness, which is frequently, at present (and will be more so) out of all proportion to the number of paupers; nor is it in the least suitable for small and distant parishes. This, indeed, he admits, and proposes that medical men should make distinct charges for medicines and attendance in these cases,—a mode which, however desirable to *us*, would not be listened to for a moment by the public.

I know of no plan which will so readily, simply, and effectually, meet the difficulty, as a certain payment for each case of illness. This is now so odious to medical men, from the manner in which the Poor Law Commissioners have effected it, and the unnecessary and unfair conditions with which they have accompanied it, that it is with diffidence as to its reception with my medical brethren, though with confidence in the correctness of its principle, that I venture to recommend it.

I am prepared, from authentic data, to prove, that where numerous patients are comprised within a small space, and close at hand to the medical officer, the sum of 3*s.* for each case will make a sufficient salary; at any rate this ought to be the lowest: and though we might with justice to ourselves state a higher minimum, yet the peculiar and delicate circumstances in which we are placed while engaged in the present discussion—the importance of not burdening the landed interest more than is absolutely necessary, and the desirableness of establishing a better system, even at some sacrifice on our part—induce me to name that sum.

There must, however, be an increase of this payment according to the distance of patients from the medical officer, and according to the total number of patients he attends in a given time; it being obvious that 1000 cases occurring within a short walk of the medical man's residence during one year, may be attended at less per head than 50 at five miles' distance in the same period.

After considerable trouble, and a comparison of numerous parochial salaries, I am disposed to believe that the following scale will answer the purpose of both the payers and the surgeons.

Distance of the Patients from the Medical Officer being within	The Number of Cases of Sickness and Accident attended in each Parish during one Year being 25	50	100	200	400	800	1600
	s. d.	*s. d.*	*s. d.*	*s. d.*	*s. d.*	*s. d.*	*s. d.*
1 mile	6 0	5 6	5 0	4 6	4 0	3 6	3 0
2 miles	6 4	5 10	5 4	4 10	4 4	3 10	3 4
3 —	6 8	6 2	5 8	5 2	4 8	4 2	3 8
4 —	7 0	6 6	6 0	5 6	5 0	4 6	4 0
5 —	7 4	6 10	6 4	5 10	5 4	4 10	4 4
6 —	7 8	7 2	6 8	6 2	5 8	5 2	4 8

Example—If the total number of patients attended during one year in any parish be 400, the payment per head for such patients as live within one mile of the surgeon's residence should be 4s.; within two miles, 4s. 8d.; within four miles, 5s.; and so on. If the number of patients be intermediate between any of the numbers mentioned at the head of the scale, the payment per head should be altered proportionally. Thus, if the medical officer had attended 150 patients, the payments per head would be 4s. 9d., 5s. 1d., 5s. 5d., 5s. 9d., 6s. 1d., and 6s. 6d., according to the distances respectively.

The subdivision of the scale might be carried out yet more minutely.

One column of this scale, or some intermediate rate of payment, suited for each parish, should be agreed on by both parties at the beginning of the year (perhaps according to the number of cases attended during the previous year); otherwise either party might, by fraudulent management,

increase or reduce the sum total paid, for the same amount of labour, at the end of the year.

Every distinct and different case of illness or accident in the same individual, however close in succession, should be charged, but relapses of the same disorder occurring within one month from the date of discharge should be considered as part of the former illness (to prevent any unfair advantage being taken of the rate-payers by the medical officers).

There should be no extras, except midwifery, trusses, and vaccination. I think I am expressing the opinion of a majority of medical men in proposing that the ordinary run of pauper midwifery cases should be managed by a female midwife, the medical practitioner attending only when called in by her. This will not only be a saving to parishes, but a relief to the profession. The charge should not be less than 1*l.* 1s., with an additional allowance for mileage. Vaccination might be charged at 1s. 6d. per head, and trusses at cost price.

No practitioner should be allowed to attend paupers distant more than six miles, unless he is the nearest eligible medical resident to those paupers; when a farther charge of 4d. should be made for every additional mile in each case. Nor should any one be permitted to undertake the entire care of a parish or parishes which, during the previous year, have furnished a total of above 1000 cases, nor any firm of medical men more than 1600 cases.

The objections to a "payment per case," as effected by the Commissioners, are, I believe, these:—

1st, Because the gross charge is not allowed to exceed a certain amount; thus throwing the whole burden of any cases occurring beyond the corresponding number on the gratuitous services of the profession. This proviso is so absurd and unjust, and so opposed to the principles of a payment per case, that it must be at once relinquished.

2dly, Because the system is a temptation to the relieving officer to withhold slight cases from treatment; thereby not only defrauding the medical man, by imposing on him an undue proportion of serious cases, for a payment expressly calculated on the usual average of illness, but leading to shameful neglect of the sufferings of the poor, whose diseases, if attacked in their incipient and milder stages, might speedily give way to treatment; while, if left until the relieving officer thinks them serious enough to receive an order for attendance, they may end in long confinement, permanent injury, or even loss of life, and occasion to the parochial funds a vast increase of expenditure. This objection is so powerful and reasonable, that I freely confess that, if the relieving officer is to retain the power of granting orders for medical relief, the plan of a payment per case is totally inapplicable; and I therefore must, as *an inseparable preliminary*, contend for the entire abolition of the "order" system.

Not only for the reason just stated, but as a general remedy, I recommend that *the right of decision as to the necessity of medical attendance to sick paupers be vested solely in the medical officer*. Let there be no intervening authority between the sufferer and the person to whom he looks for aid. The only necessary check is the *subsequent* evidence of the patient's pauperism; or, in other words, an investigation into his circumstances, and his need of *parochial* assistance. For this purpose I suggested, in my former communication, that the relieving officer should, within twenty-four hours *after* the patient's application to the surgeon, decide this question; but, on reconsideration, I incline to think that this would not sufficiently remedy the present evils; that it would still leave room for much abuse; and that the relieving officer is by no means a fit judge at *any* stage of the matter. I therefore recommend that this *subsequent investigation and decision* should be made by the Board of Guardians, who might inspect the weekly list of sick applicants presented to them by the medical officer, and declare that the medical relief afforded to those individuals who do not belong *strictly* to the class of permanent paupers, is merely by way of *loan*, the payments *by the scale* for such cases being recoverable from the patients according to the provisions of the Poor Law Amendment Act, or similar provisions to be made for this especial purpose.

The "payment per case" under these regulations would, I believe, answer all the requisites with which I started; it would be in exact proportion to the amount of sickness and pauperism in the parish; it would, by the increased graduated charge according to distance from the surgeon, provide for the extent of large parishes, as well as for the remoteness of small ones; and it would remunerate the medical officer for his time and trouble, by the augmentation of the rate of payment for such parishes as afford only a *few* cases of sickness in a given time and space.

As a crowning measure to these necessary reforms, I would urge the election of the medical officers by the rate-payers of each parish, instead of by the Boards of

Guardians. I have already given my principal reasons for this in your number of November 21, and need, therefore, only remark, that the welfare of the poor is more likely to be consulted by the whole body of rate-payers than by the Guardians; that *favoritism* and collusion between medical men and a few influential persons will, by a general election, be properly guarded against; that, in connexion with the preceding measures, the absurd system of "medical districts" will thereby be abolished; and that the appointment would then possess some *credit*, and induce a superior order of practitioners to undertake the duties.

I believe that I have thus provided a remedy for every one of the evils mentioned at the beginning of this communication, which I trust will not prove too lengthy for your kind insertion.

I remain, sir,
Your obedient and obliged servant,
RURICOLA.

Jan. 9, 1836.

ATTENDANCE OF MEDICAL WITNESSES AT CORONERS' INQUESTS,

UNDER THE NEW POOR-LAW SYSTEM.

To the Editor of the Medical Gazette.

SIR,

A SHORT time since I attended a coroner's inquest on a poor man, to whose assistance I had been summoned, as the nearest practitioner. His friends being unable to defray the charge, I applied for payment to the Board of Guardians; a copy of which application, together with their reply, I subjoin.

Surely, sir, this injustice to our profession cannot long exist. I earnestly trust that Mr. Warburton will succeed in obtaining an act of parliament, in the ensuing session, securing to us a fair compensation for attendance in similar cases.

Should you concur with me in the expediency of calling the attention of the profession to this subject without delay, an early insertion will oblige

Your obedient servant,
GEORGE MAY.

Reading, January 9, 1836.

To the Board of Guardians of the Reading Union.

GENTLEMEN,—I take the liberty to remind you, that some time since I made a demand of one guinea for attendance on the inquest of —— Taylor; and, at a subsequent personal interview, was favoured with your assurance that the case should be reported to the Poor-Law Commissioners, and that your decision would be guided by their opinion.

I take leave to recal your attention to the subject, and should you determine to refuse my claim, I hope I shall not be deemed presumptuous in requesting a statement of the Commissioners' opinion; as you will perceive that not merely this particular claim, but the interests of the medical profession in similar cases, are involved in their decision.

I have the honour to be, gentlemen,
Your obedient humble servant,
GEORGE MAY.

Reading, January 5, 1836.

Reading Union, Jan. 7, 1836.

Dear sir,—I have to inform you that the Board of Guardians, in conformity with the promise they gave you, made application to the Poor Law Commissioners for instructions for their guidance in respect to the charges of medical men for attendance upon coroners' inquests; and I am directed by the Guardians to transmit, for your information, the reply of the Poor Law Commissioners to that application.

"The Poor Law Commissioners for England and Wales have to acknowledge the receipt of your letter of the 19th inst. (December), and with reference to your inquiry upon whom it devolves to defray the demand of medical men for attendance upon coroners' inquests upon the bodies of paupers, the Commissioners desire to state that they are wholly unacquainted with any authority under which the payment of witnesses at coroners' inquests, or indeed of any other expenses attending inquests, can be charged upon the Poor rates.

"I remain, dear sir,
"Your obedient humble servant,
"THOS. G. CURTIES,
"Clerk to the Board.

"*To George May, Esq.*"

PRESENT STATE OF MEDICINE IN SPAIN.

As it may be some time before we receive the full report on the State of Medicine and the Medical Institutions of Spain, which is in preparation for us by a distinguished physician and scholar of that country, we present our readers, in the meanwhile, with the following short extract of a letter, just received from our

medical correspondent at Madrid, and which possesses a melancholy interest, from the illustration it affords of the miserable state of the medical profession in that fine but long-misgoverned country.

The medical profession in Spain, as regards its present condition, is in complete harmony with every thing else;—that is to say, it is in a state of revolution. Medical men belong, and with few exceptions have always belonged, to the Liberal party; and the class of *pure Physicians* consisted, almost to a man, of warm Constitutionalists, in the year 1820. By the term pure physicians we understand, in Spain, all those who belong to the universities, in contradistinction to those who belong to the colleges of surgery. When the Constitution was overthrown in 1823, the then absolute king, Ferdinand, incensed against the whole body of pure physicians, worked them all sorts of annoyance, and with much success, as you may believe. At last, and with the view of punishing them most effectually, he issued a decree, in which he commanded that no pure physician should be employed in the palace, the hospitals, or in any establishment under government; that is to say, in no public situation whatever, since in Spain all establishments are more or less under the control of the government; and, to supply their places, he converted surgeons into physicians by royal order, commanded that the colleges of surgery should be of medicine also, and created a great many young men at that time in the colleges *Physician-Surgeons* (Medico-Cirujanos, as they are called). The pure physicians, thus expelled from the court, hospitals, the establishments for mineral waters, &c., were compelled to bear their wrongs in silence till Ferdinand died. Since that event they have been in open war with the Board of Medicine, the members of which are the same physician-surgeons now to the queen as they were before to Ferdinand. Unfortunately for the pure physicians, the president of the Board, one of the physicians made by royal command, enjoys the confidence of the queen, and until lately has been able to resist the attacks, not only of the physicians, but even of the Cortes, by whom the edict of Ferdinand has been unanimously condemned. At length, however, in consequence of the late revolution, and consequent change of government, the president has resigned, and there is now a general expectation that the medical profession will be restored to order.

The present state of Spain is, as you may well believe, very adverse to the cultivation of science and literature: nobody thinks of any thing but politics. Six months ago we had only four medical journals in all Spain, and at present we have only two! The four journals were, *La Gaceta Medica* and *El Boletin de Medicina*, at Madrid; *La Biblioteca Medica*, at Zaragoza; and *Los Archivos Homiopaticos*, at Cadiz. The *Gaceta*, the journal of the physician surgeons, died two months since of inanition; and I believe the *Archivos* shared a similar fate; so that now we have only the *Boletin*, the organ of the pure physicians, and the *Biblioteca*, which has very few subscribers.—*Br. & For. Med. Rev.*, No. I.

RESPONSIBILITY OF PRACTITIONERS.—POISONING BY MISTAKE.

An army physician and an apothecary have been fined the sum of two and three hundred francs at Bruges, under the following circumstances. The physician had prescribed an emollient enema for one of his patients; but, as it was eleven at night, and the apothecary was in bed, he prepared it himself, with the assistance of one of the servants of the hospital. After having poured into the syringe part of the decoction of senna which he had made, he went to the dispensary, awoke the apothecary, and asked him for some linseed oil: the apothecary took down a bottle from a shelf, and put it on the counter. The physician took it away, and poured part of its contents into the syringe. Unfortunately he neither discovered, from the effervescence produced by the mixture, nor by the vapour, nor smell (all of which were remarked by the attendant), that the fluid was sulphuric acid. The clyster was given, and immediately afterwards the patient uttered the most horrible shrieks, and passed the night in acute pain: no remedies were availing, and he died.—*Journal de Chimie Medicale*, Aout 1835; *and Br. & For. Rev.*

MORISON'S PILLS.

An inquest was held at Birmingham on Tuesday (5th instant), on the body of a child 16 months old, the daughter of a carpenter, named Maullin, who died from great exhaustion, after having had several of Morison's pills administered to her by her father. Dr. Burt Davies, and other medical men, who examined the body of the child after death, said that the stomach and intestines were ulcerated, which they attributed to the action of drastic purgatives. The jury returned the following verdict:—"That Mary Hadley Maullin's

death was occasioned by Morison's pills having been improperly administered."—*Times*, Jan. 9, 1835.

THE SIAMESE TWINS.

This inseparable pair are now at Paris. M. Geoffroy de St. Hilaire congratulates the savans of the Academy of Sciences on the circumstance. Six years ago, he says, he applied in vain to the French government to allow this "teratological curiosity" to enter France. It may now be examined at leisure; and will be found deserving of attention, not only from the singular mode in which the individuals are united, but as presenting a specimen of a race of men little known to Europeans. M. Coste has visited these singular strangers, and raised rather a curious question about them; namely, at what epoch during uterine life their union took place? He has satisfied himself that it occurred *during the last days of the first month of pregnancy!* When the Twins were in London, about six years ago, they were minutely inspected by some of our ablest anatomists, and an account of the results will be found on record in our pages: see Med. Gazette, vol. 5.

URINARY CALCULI IN INSECTS.

M. Audouin has succeeded in analysing two minute calculi, found in what have been hitherto called—improperly, as it appears—the *hepatic* ducts of a stag-beetle (*Lucanus capreolus*). They were found to consist of uric acid: treated with nitric acid they yielded purpuric acid, characterised by its beautiful red colour on evaporation. The ducts in which these calculi were contained must, of course, in future, be considered as rather belonging to the urinary organs.—*Gazette Médicale.*

MEDICAL PRACTITIONERS IN PARIS.

It appears from the General Medical Almanac of Paris, just published, that the number of Doctors of Medicine or Surgery for the present year is 1220, being an increase of about 250 since 1833. Of the 1220 practitioners of Paris, there are 3 commanders, 34 officers, and 255 chevaliers, of the Order of the Legion of Honour.

CHAIR OF CLINIQUE EXTERNE.

Eight candidates dispute the chair left vacant by Dupuytren. Among them are MM. Sanson, Blandin, Berard, jun., and Lepelletier de Mans. Baron Richerand is president of the jury, and Lisfranc one of that body.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

January 14, 1836.

Henry Glasspoole, Watford, Herts.
Thomas Hankins, Faversham.
Robert Marsh Rendall, Merriott, Somersetshire.
John Langfield Burnard, Crewkerne.
John Brownfield, Norwich.
Charles Smith Meeke, Birmingham.
Stephen Hill, Handsworth.
John Darley Charles, Stow-on-the-Wold.

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XVII.

EFFECTS AND USES OF CANTHARIDES.

Physiological effects of cantharides.—Cantharides are distinguished from all mineral and vegetable substances by a threefold operation on the body, namely, a vesicating effect when applied to the skin, a specific action on the urino-genital apparatus, and a powerful influence over the functions of the brain and spinal marrow. Many insects, some of which I shall hereafter notice, also possess these properties in common with cantharides; but I repeat, I know no vegetable or mineral substance which has all of them. Sundelin, who acknowledges that these animals hardly bear comparison with other remedies, says that perhaps Mezereon bark approaches nearest to them. But this substance has no marked action on the urinary and genital organs; while its operation on the skin and the nervous system is considerably less.

1. *Local effects.*— On all living parts these insects operate as powerful acrids or irritants, giving rise to violent inflammation, but without exciting any chemical influence, so that they do not deserve the name of *corrosives*, given them by some toxicologists.

When applied to the *skin*, the first effects noticed are, a sensation of heat accompanied by pain, redness, and slight swelling. These phenomena are soon followed by a serous effusion between the corium and epidermis, by which the latter is raised, forming what is commonly termed a *blister*, or, in the more precise language of the cutaneous pathologist, an *ampulla*, or *bulla*. The effused liquid has a pale yellow colour, with a very feeble taste and smell. Two analyses of it have been made.

Analysis by Dr. Bostock.

Albumen	6·00
Uncoagulable matter	0·14
Salts	1·00
Water	92·86
	100·00

Analysis by Brandes and Reimann.

Albumen	5·75
Animal matter, with muriate of ammonia, potash salts, carbonate, lactate, muriate, and sulphate of soda	0·26
Water	93·99
	100.00

If the cuticle be removed, the subjacent corium is seen intensely reddened, and, by exposure to the air, oftentimes becomes exceedingly painful. If irritants be applied, a secretion of pus takes place, and sometimes a whitish-looking false membrane is formed. Long-continued irritation occasionally causes tubercular granulations, arising, as Rayer says, from hypertrophy of the papillæ. Not unfrequently I have noticed ecthymatous pustules around the blistered surface; and in one remarkable case the whole body, but more especially the pectoral region (to which the blister had been applied), was covered with them. Sometimes the vesicles of eczema occur. Ulceration and gangrene are not uncommon: the latter effect is occasionally observed after exanthematous diseases, especially measles. I have seen death result therefrom in two instances.

The constitutional symptoms frequently produced are, excitement of the vascular system (as denoted by the increased frequency of pulse, heat of skin, and furred tongue), and irritation of the urinary and genital organs (marked by heat and pain in passing the urine, which is usually high-coloured, or there may be complete suppression.) It not unfrequently happens that the part to which a blister has been applied remains considerably darker coloured than the surrounding skin. Rayer states that the disappearance of these discolorations is hastened by the use of sulphurous baths.

When swallowed, cantharides act topically on the *gastro-intestinal membrane*; in poisonous quantities exciting inflammation of the mucous lining of the alimentary canal, accompanied with constriction and difficulty of swallowing, which is sometimes so great, that not a particle of fluid can be got into the stomach without the most inexpressible anguish: violent and burning pain, nausea, vomiting, frequently of bloody matters, sometimes with flakes like the inner lining of the alimentary tube, and great tenderness to touch. These phenomena sufficiently indicate the gastric inflammation. Ptyalism is not an uncommon occurrence. The enteritic symptoms are, abundant and frequent evacuations sometimes of blood, with horrible griping and burning pain, and exquisite sensibility of the abdomen.

The *volatile odorous matter* evolved by these insects is a local irritant; for it causes itching and even inflammation of the eyelids and conjunctiva, irritation of the air passages, marked by epistaxis, convulsive sneezing, &c.

Applied to *wounds*, cantharides act also as local irritants, causing active inflammation. In a dog, Orfila found that death took place therefrom in 32 hours.

2. *Remote effects.*—In addition to the local effects just described, cantharides produce disorder of parts remote from those to which the insects are applied. Thus, by inhaling the volatile odorous matter, as is done when persons sit under trees on which the animals are found, or by breathing the vapour of the decoction of cantharides, an affection of the urinary organs may be brought on. The same remote effects may also be excited by blisters, by handling the insects, by applying them to wounds, by swallowing them, or by injecting solutions of their active principle into the veins. We may classify the remote effects of cantharides into those observed in the urino-genital, the nervous, and the vascular systems.

(*a*) *Action on the urino-genital system.*—The pain in the loins, and the alteration in the quantity and quality of the urine, are the symptoms indicative of the inflamed condition of the kidneys. The burning pain and tenderness in the hypogastric region, and the constant desire to pass the urine, with the inability of doing so except drop by drop, are evidences of the vesical inflammation. The action on the genital organs in the male, is proved by priapism, which is sometimes accompanied by satyriasis, sometimes not; and by the occasional inflammation and mortification of the external organs. In the female, the action on the sexual system is shewn by the local heat and irritation, and by abortion.

(*b*) *Action on the nervous system.*—The affection of this system is proved by the pain in the head, disordered intellect, manifested in the form of furious or phrenitic delirium, convulsions of the tetanic kind, and subsequently coma. It is deserving of especial notice, that sometimes several days elapse before the nervous symptoms show themselves: thus, in a case related by Giulio, they appeared on the third day; in another instance mentioned by Graaf, on the eighth; and in a case noticed by Dr. Ives, they were not observed until the fourteenth day.

(*c*) *Action on the vascular system.*—The pulse becomes hard and frequent, the skin hot, and the respiration quickened; diaphoresis is occasionally observed.

In the account now given of the action of cantharides, I have disregarded the order in which the symptoms occurred, as also the modifications resulting from varying quantities, that I might the better fix your attention on the nature and locality of the effects. My next object is to examine the operation of different doses, and the symptoms, in the order of their occurrence. I may premise, however, that the susceptibility to the influence of cantharides is very unequal in different persons. Werlhoff mentions the case of a lad who used to be attacked with priapism and involuntary emission by merely smelling the powder. Amoreux says, in one case a pinch of the powder caused death; while in another a spoonful occasioned only slight heat in the throat and ardor urinæ. Dr. Hosack has mentioned an instance in which a man took nearly six ounces of the tincture, with the view of self-destruction, yet no dangerous symptoms followed. In contrast with this, I may instance a case that came within my own knowledge, where one ounce of the tincture produced serious symptoms. Orfila has seen twenty-four grains of the powder prove fatal.

1. *Action in small or medicinal doses.*—In very small quantities there are no obvious effects. If we increase the dose, a sensation of warmth is felt in the throat,

stomach, and respiratory passages, with increased secretion from the alimentary tube. By continued use, a tickling or burning sensation is experienced in the urethra, with frequent desire to pass the urine, which may or may not be altered in quality or quantity. In some cases diuresis is observed, in others not: in the latter the urine is generally higher coloured than usual. Occasionally the sexual feelings are excited.

2. *Action in larger doses: Subacute poisoning.*—The symptoms are here more marked. We observe heat in the throat, stomach, intestines, and respiratory passages; pain in the loins, burning sensation in the bladder, with frequent desire to evacuate the urine, which is sometimes bloody, and passed with difficulty. Painful priapism, with or without satyriasis. Pulse more frequent, skin hot, and the respiration quickened: the nervous system frequently excited.

3. *Action in still larger doses: Acute poisoning.* — The symptoms observed are, in part, common to other irritant poisons, in part peculiar to the vesicating insects. Violent burning pain in the stomach, with exquisite sensibility and constant vomiting; extreme thirst, dryness, and fœtid odour of the mouth, and not unfrequently ptyalism. Burning pain and spasmodic contraction of the bladder, giving rise to the most excruciating agony. Notwithstanding the incessant desire to void urine, nothing but drops of blood are passed, and with great pain. The constriction of the throat and difficulty of deglutition are most distressing and alarming: the unfortunate sufferer is constantly tormented with violent gripings, purging, generally of blood, extreme tenderness of the whole abdominal surface, faintings, giddiness, convulsions, and an almost hydrophobic aversion to liquids, with delirium terminating in coma.

The mode, and the immediate cause of death, are various: sometimes the nervous symptoms kill before gangrene makes its appearance; but more usually the patient dies from the inflammation and subsequent mortification of the alimentary tube or of the genital organs.

Cases.—You will find several illustrative cases detailed in Orfila's Toxicology, and references made to others, in the valuable work of Dr. Christison on Poisons. The following is taken from Hufeland's Journal:—

In 1820, four men swallowed some tincture of cantharides, mistaking it for a liqueur. In half an hour, nausea, vertigo, and a sensation of burning in the mouth and throat, had come on. Within an hour these symptoms had increased, with vomiting and violent pain in the bowels. Graaf being called in, found them in a most miserable condition. Their symptoms were, sense of suffocation, vomiting of blood, burning sensation in the œsophagus and alimentary canal, incessant thirst, with incapability of swallowing. Large pieces, apparently of the inner lining of the throat and gullet, were brought up. The abdomen was tense and painful. The remedies employed were warm baths, demulcent and oleaginous substances, and leeches. During the night they were restless and in great agony, but towards morning procured some sleep.

On the second day fever appeared: the thirst was more violent, and the deglutition difficult; the pain in the bowels was very severe, and the lips were sore. The tongue was deprived of its outer covering; the palate dark brown. As yet there was no retention of urine, though the desire to pass it became more frequent. Soon, however, strangury came on, and gradually increased. The remedies employed were camphor and emulsions internally, emollient clysters with opium, and frictions with camphorated oil. By these means, the difficulty and pain in evacuating the urine were alleviated

On the fourth day the patients were much better, though two of them yet suffered severely. In one, the secretion of urine seemed wholly stopped, clots of blood only being evacuated. The catheter was introduced, but without the smallest quantity of urine passing. A tepid injection into the bladder was used with advantage. Camphor and gum were given internally, while the oil of turpentine was employed externally. In 24 hours the urinary secretion was established, and in three weeks this patient had recovered.

One of the four (a man forty years old) soon lost the strangury, but was seized on the eighth day with violent nephritis, and such terrible phrenzy that four men were required to hold him. By bloodletting and the employment of leeches, giving camphor and calomel internally, and applying cold to the head, the symptoms disappeared in three days.

Although there are several reasons for believing that Toffania and the Marchioness de Brinvillier employed arsenical mixtures for poisoning, yet it has been supposed that they did not confine themselves to one poison, but used several; one of which has been stated to be a mixture of opium and cantharides. I must refer you, however, to Beckmann's article on secret poisoning, for further information on this point.

Lesions of texture.—On opening the bodies of persons poisoned by cantharides,

the usual appearances are inflammation of the alimentary tube, of the urinary and genital organs, and congestion of the cerebral vessels. In a man who died ten weeks after having swallowed some in a frolic, on the internal surface of the stomach were found "fungous tubercles, varices, erosions, and little ulcerations." In a female who died on the fourth day after taking two doses of twenty-four grains, the mouth and tongue were stripped of their lining membrane; the œsophagus, stomach, intestines, omentum, peritoneum, and internal parts of generation, were found inflamed. In a case related by Dr. Ives, "the blood-vessels of the brain and cerebellum were gorged, the cerebellum spread over with lymph, the villous coat of the stomach softened and brittle, and the kidneys inflamed and presenting blood in their pelvis." Bonnet, in one case, found ulceration of the bladder. It is deserving of remark, that inflammation of the urino-genital organs is more likely to be met with in patients dying within a few days after poisoning. Foster, in his experiments on dogs, frequently observed the particles of cantharides in the evacuated fæces. In my last lecture, I alluded to the fact that cantharides do not readily undergo decomposition, but have been recognized in a body after nine months interment. I have also pointed out to you the advantages to be derived therefrom in medico-legal investigations.

Effects of cantharidin. — Robiquet thus describes the effects of cantharidin:— The 1-100th part of a grain, placed on a slip of paper and applied to the edge of the lower lip, caused, in about a quarter of an hour, small blisters. A little cerate being applied, served only to extend the action over a larger surface, and both lips were in consequence covered with blisters. Some atoms of cantharidin, dissolved in two or three drops of almond oil, were rubbed over a small piece of paper and applied to the arm; in six hours a blister was formed, the size of the paper. The volatility of cantharidin at a comparatively low temperature, and the action of the vapour on the conjunctival membrane, are shown by the accident which happened to one of Robiquet's pupils, and which I mentioned in the last lecture. I have suffered once in preparing this substance. I applied one drop of an ætherial solution of impure cantharidin to the inside of the lower lip; but immediately afterwards, repenting of my temerity, I wiped it carefully off. In about an hour a blister had formed on the inside of the lip, and it was five or six days before the part had completely healed. Bretonneau, in his experiments on animals, has not found any marked aphrodisiac effect produced by cantharidin. He observed that this substance rendered the circulation slower and caused lethargy, which terminated fatally.

Modus operandi.—There are certain theoretical points connected with the operation of cantharides, worthy of notice.

1. *Theory of the local action.*—The topical effects of Spanish flies depend on cantharidin, and possibly on the volatile odorous oil also. These appear to act primarily on the nerves, and secondarily on the vessels of the part. Hence, in certain affections of the nervous system, blisters will not excite vesication. I have several times noticed this in apoplectic cases.

2. *Theory of the remote action.*—It has not yet been positively determined whether the remote effects of cantharides arise from absorption, or sympathy. The usual explanation is, that the active principle being carried into the blood, is thrown out of the system by the kidneys; that in passing through the renal vessels it irritates them, and thus excites nephritis; and that the urine, loaded with this acrid matter, coming in contact with the bladder, causes the vesical symptoms. But as the cantharidin has not yet been detected in the urine (for want of sufficient chemical characters to recognize it), the theory cannot be considered as proved. The principal argument in favour of it, is the powerful effect which blisters have on the bladder, and the influence of a piece of gauze, or tissue paper, placed between the blister and the skin, in preventing this. If the urine contain the cantharidin, I should think there would be no difficulty in detecting it by evaporating to dryness, and digesting the residue with æther. Let the ætherial solution be concentrated by spontaneous evaporation, and then try its vesicating properties.

Uses.—Hippocrates used vesicating insects (under the name of cantharides) internally; but the practice was subsequently regarded as dangerous, for, so lately as the year 1693, the President of the College of Physicians committed Dr. Groenfelt to Newgate for daring to employ them!!

1. *Local uses.*—Cantharides are frequently used as topical agents; sometimes as stimulants, sometimes as rubefacients, at other times as vesicants. Archigenes, and subsequently Aretæus, are the first persons recorded to have employed cantharides externally.

(*a*) *To stimulate topically.*—Tincture of cantharides with water (in the proportion of three or four drachms of the tincture to a pint of water) has been employed to stimulate ulcers; more especially sinuses and fistulous sores. It is used on the same

principle that stimulant and irritant applications are made to the eye in ophthalmia—that is, to excite a new action, which shall supersede the old one. We are told by Dr. Paris, that Matthew's once celebrated injection for fistula in ano, is a wash of this kind. In alopecia, or baldness, when this is not the result of old age, unguents of cantharides have been employed to promote the growth of hair. Powdered cantharides have been advised as an application to the parts bitten by rabid animals.

(*b*) *To produce rubefaction.*—For this purpose the tincture may be mixed with soap or camphor liniment; or when it is desirable to limit the effect to a particular spot, and especially if friction be objectionable, the common blistering plaster may be applied, allowing it to remain in contact with the part for an hour or two only. Rubefacient liniments are employed to excite the sensibility of the skin in numbness and paralysis; as also to produce local irritation in neuralgic and rheumatic pains. In the inflammatory affections of children, you will occasionally find it useful to employ the plaster merely as a rubefacient.

(*c*) *To excite vesication.*—A considerable number of substances (mineral, vegetable, and animal) cause vesication when applied to the skin. Horse-radish, mezereon, liquor ammoniæ, and acetic acid, may be mentioned as examples. To these may be added heat, applied in the form of hot water or a hot metallic plate. For facility of application, certainty of effect, and slightness of pain, no agents are equal to the vesicating insects; and these are now almost solely used.

It was formerly supposed that the efficacy of blisters was in proportion to the quantity of fluid discharged. It is hardly necessary I should say that this notion is incorrect; the truth being that the therapeutic influence is in proportion to the local irritation, and has no more relation to the quantity of fluid discharged, than that the latter is frequently (not invariably) in the ratio of the former. Stoll's axiom is therefore correct:—"Non suppuratio sed stimulus prodest." As to the precise manner in which blisters, or indeed any remedies, influence diseases, we are quite in the dark. We are accustomed to refer their operation to the principle of counter-irritation, already discussed in a previous part of the course. I must refer those who feel interested in the question, whether blisters ought to be applied in the neighbourhood of, or at a distance from, the affected part, to a paper by Barthez, in the *Recueil de la Société Médicale de Paris*. In this country we generally apply them near to the morbid part; to which practice Barthez assents, with some exceptions.

We employ blisters in inflammatory diseases, both acute and chronic; in the former, however, preceding their use by blood-letting. In chronic inflammatory diseases we often employ what is termed a perpetual blister—that is, remove the cuticle from the ampulla, and dress with savin or cantharides ointment. This practice is advisable in chronic diseases of the chest, of the joints, of the eyes, &c. Blisters are sometimes useful in erysipelas; thus to localize the disease, when disposed to spread, and as a revulsive applied to the feet, in erysipelas of the head. A blister to the perineum has been sometimes found beneficial in gleet.

It is hardly safe to apply blisters to children immediately after exanthematous diseases, sloughing being not an unfrequent result. If you want to cause counter-irritation, the best plan is to dilute the common blistering plaster, by mixing it with three times its weight of soap cerate. I have seen this frequently employed, but never observed any unpleasant results. Another plan sometimes adopted is to apply a common blister, for an hour or two only, so that it shall merely produce rubefaction.

2. *Remote uses.*—These will require examination under distinct heads, according to the particular object we have in view in employing cantharides.

(*a*) *To act specifically on the urinary organs.*—Sometimes we employ cantharides to act specifically on the kidneys and bladder. Thus in dropsy they have been used to excite diuresis, though they frequently fail in producing this effect. In fact, both Dr. S. Carmichael and Dr. Cullen state they never succeeded with the remedy. In that curious and intractable disease, diabetes, cantharides have been employed, but without apparent benefit. In paralysis of the bladder they are frequently useful, when there are no marks of local irritation. You are no doubt aware that either of two opposite conditions may be the result of paralysis of this organ, namely, retention and incontinence of urine. The latter condition is not unfrequently met with in children, and is very likely to be relieved by cantharides. We are told that these insects are particularly serviceable in that species of incontinence which occurs during sleep only; but I have seen them cure the disease during day, and fail in giving relief at night. The case alluded to was that of a boy, 14 years old, who had been subject to incontinence of urine since his infancy. He was a robust lad, and apparently in the most perfect health. I put him under the influence of gradually-increased doses of

tincture of cantharides, and within two months he was enabled to retain his urine by day, but it still passed involuntarily at night; and though he continued the remedy for a considerable time, no further benefit was obtained. You will also find cantharides useful in that form of incontinence of urine which occurs after lingering labours from the long-continued pressure of the child's head. You must not, however, commence the use of this remedy until all symptoms of local irritation have subsided.

(*b*) *To act on the organs of generation.*—In consequence of the specific stimulus exerted by cantharides on the bladder, it has been supposed that the effect might be extended to the uterus; and thus they have been employed as stimulating emmenagogues, in some cases with apparent benefit, but frequently without any obvious effect. Abortion has occasionally happened from their employment, as I have myself witnessed in one case.

Cantharides are also employed as an aphrodisiac, both in man and other animals (as horses, heifers, and asses). In man, if given in sufficient quantity to affect the sexual feelings, it endangers the patient's safety. Most of the cases in which we are requested to administer aphrodisiacs, will be found, on examination, to require moral rather than pharmacological treatment. In discharges from the genital organs, beneficial effects are frequently obtained by the internal use of cantharides. In gleet it has been often found serviceable. Mr. Roberton, who has published a work on its use in this complaint, explains its efficacy by saying, it excites a mild inflammatory action in the urethra, which supersedes the previous morbid one: this is shewn by the discharge becoming thick, opaque, and puriform. Mr. Roberton says cantharides are equally serviceable in leucorrhœa: in this I think he is wrong.

(*c*) *In chronic skin diseases.*—Pliny states that cantharides (*Mylabris cichorei*) were employed in a disease which he terms lichen. At the present time, tincture of cantharides is not unfrequently employed in lepra, psoriasis, and eczema. Having found other remedies very successful in lepra and psoriasis, I have rarely had occasion to try cantharides; but Rayer, in his elaborate treatise on the Diseases of the Skin, says, "Of all the energetic and dangerous remedies that have been used in lepra, the tincture of cantharides is, perhaps, that which has the most remarkable influence over the disease. The great objection to its employment is its liability to excite inflammation in the digestive organs and urinary passages, especially among females, which necessitates the immediate suspension, and occasionally the entire abandonment of the medicine." Biett has found it successful in chronic eczema, as well as in the scaly diseases.

(*d*) *In diseases of the nervous system*, cantharides were at one time in great repute. The cases in which they were employed were hydrophobia, epilepsy, chorea, tetanus, and mania. I need hardly say experience has shewn they deserve little attention in any of these complaints. If, however, you should be inclined to try them, recollect that they excite the nervous system, and are, therefore, better adapted to those cases accompanied with a deficiency rather than an excess of vascular action.

(*e*) *In obstinate sores*, Mr. Roberton has employed cantharides on the same principle as he uses them in gleet.

Preparations.—It is, I conceive, quite unnecessary for me to give a description of all the preparations that have been or may be made of cantharides. I must refer you to Jourdan's *Pharmacopée Universelle* for a most complete account of all those at present used in Europe, and shall confine myself to the preparations employed in this country.

1. *Tincture of cantharides.*—If you wish to exhibit cantharides internally, by far the safest plan is to extract the active principle by some solvent. Now æther, alcohol, water, proof spirit, or oil (fixed or volatile), may be employed for this purpose. In this country, a tincture made with proof spirit is used. The strength of this preparation varies in the three British Pharmacopœias,—a circumstance much to be regretted. In the London Pharmacopœia, the proportions are three drachms of cantharides to two pints of proof spirit. The dose of this preparation for an adult is ten or twelve minims, gradually increased to a drachm. You had better exhibit it in some demulcent liquid, as linseed-tea or barley-water, always carefully watching the effects on the system, more especially on the urinary organs.

2. *Plaster of cantharides.*—This is the well-known *blistering plaster.* Here again the formulæ of the three Colleges are not uniform in their strength. In the London Pharmacopœia, 1 part of cantharides is employed with $2\frac{1}{2}$ parts of a base (composed of wax, suet, lard, and resin). I have already alluded to the practice of some druggists in diminishing the weight of the cantharides, and substituting powdered euphorbium. In making blistering plaster, it is necessary to be aware, that if the cantharides be added to the base while the latter is very hot, their vesicating power is diminished, and hence they are never to be mixed in until the other in-

gredients are nearly cold. This plaster is usually spread on leather by the thumb (a heated spatula being objectionable, for the reason already mentioned). To prevent the blister moving, its margin is to be covered with adhesive plaster. And in order to guard against any affection of the urinary organs, place a piece of gauze or silver paper between the plaster and the skin. The efficacy of the blister depends on the fatty matter dissolving the cantharidin and transuding through the muslin or paper. Some recommend the paper to be soaked in oil, which is supposed to dissolve the cantharidin. Now oil, not being miscible with the blood, is not readily absorbed; and hence, it is supposed, arises its protective influence.

The usual time requisite for a blistering plaster to remain in contact with the skin is twelve hours; the vesicle is then to be cut at its most depending part, and dressed with spermaceti ointment. When the irritation caused by these plasters is excessive, it is sometimes necessary to substitute a poultice for the ointment. When we wish to make a perpetual blister, the cerate of cantharides is employed as a dressing; or if we wish to excite less irritation, and prevent the possibility of the urinary organs being affected, the cerate of savine.

3. *Cerate or ointment of cantharides.*—In the London Pharmacopœia, this is prepared by adding one part of powdered cantharides to six parts of spermaceti cerate. But the Dublin College order an ointment composed of a decoction of cantharides and ointment of white resin, evaporated to a proper consistence. This is a less irritant application than that in the London Pharmacopœia. Both of them are employed to excite a purulent discharge from blistered surfaces.

4. *Ointment of cantharidin.*—According to Thierry a very active ointment is made by incorporating one grain of cantharidin with one ounce of lard. In order that the active principle may be properly mixed, it should be dissolved in alcohol. A little essential oil may be added, to render the ointment odorous.

Method of treating cases of poisoning by cantharides.—In all cases of poisoning, the first object is to expel the poisonous substance from the stomach. It is not, however, always necessary, or even proper, that, to attain this object, we should use the stomach-pump, or exhibit emetics. When the poison is a powerful irritant, it causes inflammation of the stomach and vomiting; and when these effects have taken place, emetics can only add to the irritation, without being serviceable. Sometimes it is impossible to introduce the tube of the stomach-pump; and even if it were practicable to effect this, we should only increase the patient's danger. These remarks apply particularly to the treatment of poisoning by cantharides, in which both the stomach-pump and emetics are to be prohibited, unless, indeed, the accident shall have been discovered before the vomiting has commenced, in which case emetics may be exhibited, and the throat tickled to excite sickness. No antidotes are known. Oil was at one time thought to be an excellent remedy, but subsequent experience is against this opinion. Cantharidin is, as I have before mentioned, very soluble in oil; and hence, instead of alleviating, it has been supposed to add to the patient's danger, by extracting the activity of the flies, and thereby assisting their operation on the stomach. This theoretical view of the subject, first broached, I believe, by Pallas, seems supported by experience. Orfila found that cantharides macerated in cold oil, and afterwards given to dogs, killed them in a few minutes; and Dr. Christison says, "The case mentioned in the Genoa memoirs was evidently exasperated by the use of oil." I confess, however, I think farther experience is required to determine the hurtful consequences of employing oil; for as the editors of the "*Dictionnaire de Matière Médicale*" very properly observe, on the same principles that oil is prohibited, mucilaginous drinks ought also to be proscribed, since cantharidin, aided by the yellow matter, dissolves in water; and on the other hand oil, in some cases, has appeared to be beneficial. White of egg, with water, milk, linseed tea, and other demulcents, have been recommended. Oleaginous and mucilaginous injections into the bladder are advised, in order to relieve the vesical symptoms. In addition to these means, blood-letting, general and local, opium, and the warm bath, must be resorted to.

Other Coleopterous Vesicants.

I have already several times alluded to other vesicating insects besides the common Spanish fly employed in this country. They belong to four genera, namely, *cantharis* (or *lytta*), *meloe*, *mylabris*, and *lydus*.

I. The genus Cantharis, or *lytta*, contains the following species, which have been employed as vesicants:—

1. *Cantharis vesicatoria*, already described. Though very uncommon in this country, it is regarded as indigenous; and is accordingly described and figured in Donovan's "*British Insects*," and enumerated in Stephens's "*Catalogue of British Insects.*"
2. *C. vittata*, or *potatoe fly* of North America. It contains *cantharidin*, and has been frequently employed as a sub

stitute for the first-mentioned species. It is officinal in the "*Pharmacopœia of the United States.*"

3. *C. atrata* is also a native of North America, and is mentioned as a blistering insect.
4. *C. marginata*, an American insect, possessing vesicating properties.
5. *C. cinerea*, another North American blistering insect.
6. *C. ruficeps*, a native of Sumatra and Java, possessing, according to Waitz, extraordinary blistering properties.
7. *C. gigas*, a native of Guinea and the East Indies. It is described by Pfaff as *Lytta cærulea*.
8. *C. violacea*, a native of the East Indies. This is the *Lytta gigas mas* of Buchner.
9. *C. atomaria*, a native of the Brazils, where it is said to be employed.
10. *C. syriaca*, or *Lytta segetum*, is probably the *green cantharides*, said by Forskal, in his *Materia Medica Rahisina*, to be employed in Arabia.

II. The genus Meloe (*May worm*, or *Oil beetle*) contains also a large number of species which have been employed medicinally; some of them are indigenous. In the 11th volume of the Transactions of the Linnæan Society, you will find a description of the British species, by Mr. W. E. Leach.

1. *M. majalis*, or *true May worm.*
2. *M. proscarabeus.* This is the *Proscarabeus vulgaris* of Stephens, and is a native of this country. Both this and the preceding species are found in Portugal, Spain, France, &c., and are officinal in several of the European Pharmacopœias. Their operation is similar to cantharides, and they are believed to contain the same active principle. *M. proscarabeus* has produced death in two instances.

III. The genus Mylabris contains two species deserving of notice:—

1. *M. cichorei.* This is a native of the East Indies and China. I have already stated the reasons for believing that it was the insect mentioned by Dioscorides and Pliny, and perhaps also by Hippocrates, under the name of κανθαρις. It contains the same active principle, and is quite as powerful, as our common blistering fly (*Cantharis vesicatoria.*)
2. *M. sidæ*, or *M. pustulata*, is a native of the Cape of Good Hope. It is said to be employed in China.

IV. The genus Lydus yields one species (*L. trimaculatus*), which is said by Referstein to be employed in the northern parts of Europe as a blistering insect.

ON THE

NERVOUS SYSTEM;

Being a Lecture, delivered at the Aldersgate School of Medicine, on Jan. 6, 1836,

By Marshall Hall, M.D. F.R.S., &c. &c.

Gentlemen,—I am about to bring before you an important class of diseases,—that of the Diseases of the Nervous System.

I have, for some years, been prosecuting this subject; but I find it so extensive, that, even after so considerable a period, I am only enabled to present you with a slight *sketch* of the plan and objects of my investigations, the results of which will, in due time, be submitted to the Royal, and Royal Medical and Chirurgical, Societies.

I have endeavoured to pursue this inquiry through the medium of anatomy, physiology, and pathology; but my aim has also continually been to improve the diagnosis and practice. I think that the science and art of medicine are by no means incompatible acquirements, and that the boast of being a mere practitioner should cease to be a cloak for ignorance and indolence. To pretend to understand the diseases of the nervous system without an intimate knowledge of its anatomy, physiology, and pathology, is the height of folly and presumption. The *symptoms* of these diseases can be justly interpreted by the anatomist, the pathologist, alone; and an accurate knowledge of the symptoms is absolutely necessary to practice: it is the principal source of the diagnosis, and our constant guide in the administration of remedies.

Nor is a knowledge of the structure and functions, the anatomy and physiology, of the nervous system, sufficient alone, for the understanding of the diseases of this system. The nervous system does not exercise its functions uninfluenced by the other systems of the animal economy, or by the general system as a whole. The influence of these upon the nervous system must be clearly understood, before the view of the subject can be said to be complete.

Indeed, the entire economy of the human frame, although constituted by various systems, is one and indivisible, and it is impossible that one of those systems should be morbidly affected without the participation of the rest. In order to accommodate this difficult and complicated subject to our limited understanding, it has been found necessary, however, in the pursuit of medical science, to proceed ana-

lytically, and to imagine the different systems of which the whole animal economy is composed to be separated so as to admit of distinct examination; and we speak of the nervous, the circulatory, the respiratory, the digestive, the urinary systems, &c. as distinct objects of inquiry. We are compelled, however, afterwards, to review the subject synthetically, and to consider the influences of one or more of these systems, or of the general system, upon the other systems, respectively.

On the present occasion I proceed to treat, in this manner, of the nervous system; or of that system by means of which we are connected, through sensation and perception, volition and voluntary motion, with the external world;—that system by means of which the *ingesta* and *egesta* of the animal economy are regulated;—that system by the agency of which, out of the ingesta, the various organs, limbs, &c. are formed and nourished.

The first objects which will occupy us will be the anatomy and physiology of the nervous system: we shall then consider its pathology. This will naturally lead us to consider the distinct diseases to which this system is liable. We shall then trace the influence of morbid states of the other systems taken individually, and of the general system, upon the nervous system. This plan will be pursued both in regard to the adult and the infant.

I.—*Of the Anatomy of the Nervous System.*

I believe all anatomists have divided the nervous system into the cerebro-spinal and the sympathetic. The first of these is represented in this plate by M. Manec: it consists, first, of the cerebrum and cerebellum; secondly, of sentient nerves, which pursue their course to them, and of motor nerves, which proceed from them, either along the base of the brain or along the spinal marrow, in every external part of the animal frame. The second is partly represented in this other plate, by the same anatomist: it comprehends the internal ganglionic or sympathetic.

To these two subdivisions of the nervous system, I believe a third must be added, before our views of that system can be considered as at all complete;—it is one which I claim the merit of first pointing out in all its fulness. Suppose the cerebrum and cerebellum, the *centre* of the first subdivision of the nervous system, and the ganglionic, or the second subdivision of this system, removed, *this remains.* It consists of the *true* spinal marrow, distinguished from the sentient and motor nerves, which run along its course, as an *axis* of *excitor* and *motor* nerves. It is the seat of a peculiar series of physiological phenomena, and of a peculiar class of pathological affections. In the former are included *all* the funtions which relate to the immediate acts of *ingestion* and *egestion;* to the latter, *all* spasmodic diseases.

According to this view of the subject, instead of dividing the nervous system into—

I. *The cerebro-spinal*, and
II. *The ganglionic* or *sympathetic*,

I would propose to divide it thus:

I. *The cerebral*, or *the sentient* and *voluntary;*
II. *The true spinal*, or *the excito-motory;* and
III. *The ganglionic*, or *the nutrient*, *the secretory*, &c.

I think, too, that there is good reason for viewing the fifth and posterior spinal nerves as constituting an external ganglionic nerve, for the nutrition, &c. of the external organs; so that I would further propose to subdivide the ganglionic subdivision of the nervous system into—

1. The *Internal*, comprising
   1. *The sympathetic;*
   2. *The vagus?*
2. The *External*, comprising
   1. *The fifth;*
   2. *The posterior spinal.*

I must first observe, that the designation cerebro-spinal is incorrect. It comprises *two* subdivisions of the nervous system, which must be distinguished from each other, and of which the cerebrum and the true spinal marrow are the respective centre and axis. I shall proceed to treat of each of these.

The first comprises every part of the nervous system which relates to *sensation* and *volition*, the nerves of *sense*—the olfactory, the optic, the auditory, the gustatory, the nerves of touch, and the whole of the nerves of voluntary motion. Its centre is the cerebrum, including the cerebellum; its sentient nerves run variously from the organs of sense, and from the *external* surfaces, first *without* the cranium or spine, and then *within* the cranium or spine to that centre; its voluntary nerves pursue a similar but retrograde course *from* that centre to the muscles of voluntary motion.

A peculiar set of nerves constitute, with the true spinal marrow as their *axis*, the second subdivision of the nervous system. As those of the former were distinguished into sentient and voluntary, these may be distinguished into the excitor and motory. The first pursue their course principally from *internal* surfaces, characterized by peculiar excitabilities, *to* the true medulla

oblongata and spinalis; the second pursue a course from that medulla to muscles having peculiar actions concerned principally in ingestion and egestion. The motions connected with the former, or cerebral subdivision, are sometimes, nay, frequently, *spontaneous*; those connected with the true spinal are, I believe, *always excited*.

The anatomy of this subdivision is still little known. I propose the subject to myself for investigation. I will merely venture, on the present occasion, to present you with a brief outline of it, by way of example.

I. The *excitors* belong chiefly, perhaps entirely, to—

1. *The fifth*;
2. *The pneumo gastric*; and
3. *The posterior spinal nerves.*

1. The excitor branches of the first of these are distributed—

1. *To the eye-lid*;
2. *To the nostril*;
3. *To the fauces**;
4. *To the face.*

2. The excitor branches of the second—

1. *To the larynx* †;
2. *To the pharynx*;
3. *To the lungs*;
4. *To the stomach.*

3. The excitor branches of the third—

1. *To the anus*;
2. *To the cervix vesicæ*;
3. *To the cervix uteri*;
4. *To the general surface of the body.*

II. The motor branches are distributed to—

1. *The orbicularis*;
2. *The larynx*;
3. *The pharynx*;
4. *The muscles of respiration*;
5. *The sphincters*;
6. *The ejaculators*;
7. *The general muscular system.*

These arrangements will be perfectly intelligible to you when I come to speak of the physiology; but before I proceed to that part of my lecture, I must draw your attention once more to the third subdivision of the nervous system, or the ganglionic.

The *internal* ganglionic includes that usually denominated the sympathetic, and probably the vagus. The external ganglionic embraces the fifth and the posterior spinal. The arguments for these divisions are principally physiological; they will be given, therefore, in that division of my subject to which I now proceed.

* The naso-palatine; the pharyngeus?—See Bellingeri; Arnold.

† The *internal* laryngeal.

II.—*The Physiology of the Nervous System.*

In order to convey a distinct idea of my views of the nervous system at once, I shall begin by the detail of one experiment and the performance of another.

A horse was struck with the poll axe over the anterior lobes of the brain. It fell instantly, as if struck with a thunderbolt, was convulsed, and then remained motionless. It shortly began to breathe, and continued to breathe freely by the diaphragm.

When lacerated or pricked by a sharp or pointed instrument, as a strong *pin*, on any part of the face or surface of the body, it was totally motionless, manifesting no evidence of sensation or volition.

When, on the other hand, the *eye-lash* was touched with a *straw*, the eye-lid was forcibly closed by the action of the *orbicularis*. When the cornea was touched, the eye-ball was drawn outwards by the *abducens*. When the verge of the anus was touched, the sphincter contracted forcibly, the tail was raised, the vulva drawn towards the anus.

The upper part of the medulla oblongata was now destroyed by an instrument passed through the orifice made by the poll-axe: there were violent convulsions; the respiration ceased, and the eye-lid and eye-ball remained motionless on the application of stimuli.

Now I imagine that it will not be disputed that the blow of the poll-axe, in this case, annihilated the cerebral or sentient and voluntary functions; and that a peculiar set of excito-motory phenomena remained. Deep lacerations produced no evidence of the former; the touch of a straw induced a full manifestation of the latter. The destruction of the medulla oblongata removed all trace of excito-motory phenomena in the eye-lid and eye-ball.

Now you observe here this living frog. Its sentient and voluntary functions are obvious. I divide the spinal marrow, below the occiput, with these scissors: all is still. Not a trace of *spontaneous* motion. The animal would remain in this very form and position, without change, until *all* signs of vitality were extinct. But now I pinch a toe with the forceps. You see how both posterior extremities moved. All is now still again; there is no spontaneous motion, no sign of pain from the wound made in the neck. It is without sensibility—without volition; the *power* to move remains—the *will* is extinct. I now pinch the integument. You observe the

result—the immediate occurrence of excito-motory phenomena.

I now destroy the whole spinal marrow with this probe. It is in vain that I pinch the toes; the integuments, the limbs, are motionless. Could the former *excited* motions be those of irritability? I will try the truth of this suggestion by seeing whether, now that the axis of the excito-motory system is destroyed, with its phenomena, the application of a slight galvanic shock will prove the subsistence of irritability. You see how instantaneously and forcibly the muscles are stimulated to contraction.

Is not the proof, from this experiment, of the distinction between the motions of volition, of the excito-motory system, and of irritability, perfectly and unequivocally complete?

I must now proceed more systematically with my lecture.

I shall not detain you long with the physiology of the cerebral subdivision of the nervous system: it embraces sensation, perception, volition, and voluntary motion. The senses are the smell, the sight, the hearing, the taste, and the touch; they convey to the mind all we know of the external world. Perception is derived from them. Volition is a subsequent mental act, and voluntary motion a frequent result. And thus the motions which result from sensation always *imply volition;* but as volition may exist without any previous sensation, the voluntary motions are frequently *spontaneous.* It is by this character that the motions which belong to the sentient and voluntary system are distinguished from those which belong to the excito-motory. These are never spontaneous: they are *always excited.* Even the motions of respiration, as far as they belong to this system, are excited motions, as I shall shew immediately. Legallois, M. Flourens, Sir Charles Bell, are equally in error when they consider the medulla oblongata as the *source* of the respiratory motions; it is the *channel* through which the excitors act, and the organ which *combines* the different movements which constitute the acts of respiration. Equally remote from the truth, I think, is the opinion of Dr. Philip and Mr. Mayo, that the acts of the respiration are entirely voluntary. This is, in fact, a mixed function, as all the acts of the excito-motory system may be; and although generally belonging to the excito-motory system, yet capable of being affected through the medium of volition. This subject will be pursued hereafter.

A point which belongs more immediately to our present subject (the cerebral system) is that of the influence of the senses over the acts of volition. There is a most interesting case of anæsthesia, published by Dr. Yelloly, in the Transactions of the Medico-Chirurgical Society. The patient could hold a cup in her hand securely, if she kept her eyes fixed upon it; but if she ceased to look at it, it fell to the ground. I have this day seen a patient with a slight degree of paralysis of feeling and of voluntary motion in his lower limbs. He walks safely whilst his eyes are fixed upon the ground, but stumbles immediately if he attempts to walk in the dark. His own words are, "My feet are numb; I cannot tell in the dark where they are, and I cannot poise myself." The voluntary motions are regulated by the sense of touch, when this is unimpaired, or by that of sight, when the touch is paralyzed.

Many attempts have been made to *localize* the functions of the cerebrum; that is, to prove certain functions to be attached to certain parts of that organ, without, however, much success. Affections of one hemisphere paralyze the *opposite* side of the body only; so do affections confined to one side of the cerebrum, and of the tuber annulare: in the last case the paralysis is said to be confined to the *motions**. Affections of the medulla oblongata and spinalis convulse or paralyze parts situated on the *same* side of the body.

An injury inflicted upon the cerebrum or cerebellum, in experiments, induces paralysis, but not convulsions; but if the medulla be touched, either convulsion or paralysis may be the immediate effect, according to the degree of the injury.

If the medulla oblongata be seriously injured, the most instantaneous death is the consequence. Injuries to the lower parts of the medulla spinalis affect the sphincters, and the organs of generation.

I now proceed to treat of the acts of the excito motory system. As the designation of this implies, there is always the application of an appropriate stimulus, or cause of excitement or irritation; this is followed by the contraction of peculiar sets of muscles. It is clearly proved that the influence of the stimulus is carried along an excitor and incident nerve, to the medulla oblongata or medulla spinalis, and that it is reflected thence along other reflex or motor nerves. The incident excitor nerves, the medulla, and the reflex motor nerves, constitute the system. They remain, as I have already stated, after the centre of the cerebral system has been removed by experiment, or destroyed by disease.

I have already detailed the experiment of a horse, felled and reduced to a state of

* Ollivier, Traité de la Moelle épinière, Ed. ii. p. 527.

insensibility by the poll-axe. No infliction upon the skin, by a pin or other pointed instrument, was felt—no voluntary motion induced; but the touch of a straw, applied to an eye-lash, or the cornea, immediately induced a firm contraction of the orbicularis palpebræ. There can be no doubt that a filament of the first branch of the fifth pair of nerves, or trifacial, conveyed the impression to the medulla oblongata, and that a filament of the seventh pair, or facial, reconveyed it from the medulla oblongata to the orbicularis. All this is wonderful, and, I believe, quite unknown to physiologists. But the light touch of the same portion of straw applied to the verge of the anus, induced a firm contraction of its sphincter. In this case the physiology is similar; but the anatomy is unexplored. Nerves which arise from the verge of the anus take their course to the spinal marrow; from whence some mysterious influence is returned to the sphincter muscle.

Apoplexy and hydrocephalus are subjects of our daily observation: even *their* symptoms are unintelligible to any but an anatomist. In the former there is perfect coma—blindness, deafness, perhaps insensibility to impressions which would, in other circumstances, be productive of pain; yet the patient breathes, and the sphincters still do their office: one thing only is observed — the due ratio which usually subsists between the number of respirations and of the pulsations of the heart, is lost. In hydrocephalus, or the hydrocephaloid disease, there may be a dilated pupil, with total blindness; yet, although the eye remains unclosed whilst the finger or any other object approaches the cornea, a touch of the tip of an eye-lash immediately induces the closure of the eye-lids! At length, with augmented disease, this phenomenon ceases in its turn. The excitor nerve of the eye-lash loses its excitability, and the motor of the orbicularis its motor power; the eye lids are unmoved on touching the lash, and are permanently but half closed. These are interesting facts, for they not only denote the seat and the nature, but the degree of the disease.

Filaments of the fifth pair of nerves are the excitors distributed upon the border of the eye-lid and surface of the eye-ball,—upon the nostrils, probably upon the fauces, —certainly the face,—and are the *first* agents in inducing closure of the eye lid, sneezing, vomiting, and sobbing, when the eye-lash is touched, the nostrils stimulated, the fauces irritated, and cold water is dashed upon the face. Other nerves convey the reflex influence from the medulla oblongata to the orbicularis, and the various respiratory muscles whose actions are combined in the acts of sneezing, vomiting, and sobbing.

Filaments of the pneumo gastric are the excitors, when carbonic acid gas, or a drop of water, comes in contact with the larynx, —when the dust of ipecacuanha is inhaled in the bronchia with the effect of inducing asthma,—in deglutition,—in ordinary respiration,—and in the act of vomiting produced by antimony in the stomach and calculi in the gall-duct or ureter.

There are several interesting and peculiar facts connected with the excito-motory system, which I must briefly mention. If the fifth nerve in the fauces be irritated, vomiting is induced; if, on the contrary, the eighth in the pharynx be excited, the act of swallowing follows. It has happened, that when a patient has wished to excite vomiting by tickling the fauces with a feather, he has, by passing the feather down, induced such an action of the muscles of deglutition, as has carried the feather into the œsophagus. There are two cases of this kind in the Medical Observations and Inquiries, vol. iii. p. 7, and vol. ii. p. 231. A similar event has occurred with regard to the female catheter: certain nerves being excited on introducing this instrument, an action of the muscles has been induced, which has drawn the catheter out of the grasp of the surgeon into the bladder. I show you a catheter which was extracted from the bladder after such an accident. The very case is detailed in the "Medical Facts and Observations," vol. i. p. 96. Such cases are not rare even. My friend Mr Toogood, of Bridgewater, has been called to two such accidents, and extracted the catheter by the urethra. The *cause* of the occurrence had not been pointed out before. I believe a similar event has taken place in regard to the rectum.

Spinal nerves are excitors and motors in regulating the action of the sphincters, and of the ejaculatores seminis.

This important part of the nervous system entirely presides over ingestion and egestion—over the ingestion of air, of food, &c., and over the egestion of the fæces, the urine, the semen, the fœtus. In all, the presence of an excitant is essential: the act of deglutition cannot be effected without the contact of some substance with the pharynx, although the touch of the finger be sufficient. A similar remark applies to the ejaculatory muscles.——

But this subject is best illustrated by adverting to the important function and acts of the muscles of respiration. Legallois, M. Flourens, and Sir Charles Bell, have erroneously considered the acts of the respiration as spontaneous, and the medulla oblongata as their source and *primum*

mobile. I think I have, on the contrary, proved by experiments that this important function consists of excited acts, *excited* through a peculiar system of *excitor* nerves, and principally filaments of the fifth, the pneumo-gastric, and the spinal nerves. You dash cold water on the face of your patient, you pinch the pneumo-gastric in an experiment, or you sink gradually into the sea in bathing; in each case an act of inspiration is excited. Compare these nerves, too, at their origin, and you will find that they all agree in one remarkable character—that of being formed of numerous distinct filaments. A thousand other facts demonstrate the same thing: a drop of water fallen into the larynx; tickling the soles of the feet affect the muscles of the respiratory system so as to threaten death by asphyxia. The medulla oblongata*, and not the pneumo-gastric nerve†, *combines* the action of the different muscles together into acts of respiration, &c.

I perfectly agree with Sir Charles Bell in the opinion that the respiratory is perfectly distinct from the other subdivisions of the nervous system; but I venture to differ from him in viewing the respiratory as but *a part* of a more extensive system—as an *excited* and not a *spontaneous* function —as *originating*, when the cerebrum is removed, in the par vagum *as its excitor*, and not in the medulla oblongata.

But I must hasten on. I will close my remarks on this subject by stating, that however distinct the cerebral and true spinal subdivisions may be, these exert an influence upon each other which is essential to the well-being of the individual. The anencephalous fœtus, though it may be born alive, and even live for some hours, is not *viable*; it must *soon* die. Apoplexy and hydrocephalus destroy the patient, by destroying the cerebral functions merely. During sleep even, although this be *chiefly* an affection of the brain, the functions of the true spinal marrow are somewhat impaired; the respiration is noisy, frequently slightly stertorous, and irregular. Yet the respiration does proceed, acts of deglutition take place, and the sphincters do their office. Still a marked distinction between the cerebral and the true spinal functions is, that the former are partly suspended in *sleep*, and entirely in *coma*, whilst the latter are unimpaired: in sleep and in coma the eyelash is susceptible to the slightest stimulus, and the orbicularis, the sphincter of the eye-lid, and the other sphincters, with the muscles of the larynx and of the respiration, do their office. This state of things cannot last long, however, because the integrity of the cerebral functions is essential to the continuance of the true spinal and the other functions of the animal economy. Hence the fatal omen attached to stertor, choking, relaxation of the sphincters, and other morbid affections of the true spinal functions, in cases of cerebral disease.

On the other hand, if the excitor-motory system be impaired in its functions, the acts of the cerebrum are interrupted. The volition is perfect in chorea, in stammering; but the voluntary movements, from the morbid condition of the excito-motory system, are irregular and imperfect. I have this day witnessed a remarkable fact: a patient who had suffered a degree of loss of power of the left arm and leg, from a protracted epileptic seizure, and who could not close the hand firmly otherwise, could grasp any object placed in it with considerable force.

I must briefly mention one fact more. The whole *tone* of the muscular system is the result of an excito-motory function. The limbs of an animal, or of a part of an animal separated from the influence of the cerebrum, become relaxed on destroying the spinal marrow. If we remove the tail and the rectum from a recently decapitated turtle, the sphincter retains its circular form, the tail its firmness, phenomena which cease entirely on withdrawing the portion of spinal marrow remaining within the caudal spinal canal*.

The third subdivision of the nervous system embraces *all* the ganglionic nerves. I have divided it into the *internal*, which comprises the sympathetic and perhaps a part of the pneumo-gastric; and the *external*, which embraces all the other ganglionic nerves, the *fifth* especially, and the posterior spinal.

Lastly, different *remedies* act upon distinct parts of the nervous system: opium acts on the cerebral; strychnine and hydrocyanic acid on the true spinal subdivisions of that system.

The only novelty which attaches itself to this part of my division of the nervous system, is that which relates to the external ganglionic, or external nutrient, nerves.

I am not aware that any preceding inquirer has suggested the real office of the ganglia on the fifth and posterior spinal nerves. These ganglia were first observed to be attached to the portio major of the fifth and the posterior spinal nerves, not, as Sir Charles Bell states*, by Monro, but

* Recherches Expérimentales sur le Système Nerveux. p. 180, &c.
† The Nervous System, 1830, p. 46.

* See a paper by the author in the Transactions of the Royal Society for 1833.
† The Nervous System, 1830, Pref. p. vii. &c.

by Prochaska. This latter author observes, in the preface to a republication of his work in 1800:—

"Hic tractatus, qui anno 1779 prodivit, plures novas observationes circa structuram systematis nervosi a me factas continet. Harum nonnullæ, quibus in textu non fuit locus, in explicatione figurarum uberius exponuntur, ad quas spectat nova arbor vitæ corporum olivarium, vid. Tab. I. fig. 3, 4, 5; fasciculus funiculorum nerveorum quinti paris cerebri, qui insalutato ganglio semilunari sub eodem tertium ramum ejus nervi maxillarem inferiorem dictum petit, vid. Tab. II. fig. 4, 5; sic quoque radices anteriores omnium nervorum spinalium, quæ insalutata ganglia radicum posteriorum transeunt, vid. Tab. III. fig. 1, 2. Super eandem materiem plura præclara scripta isto tractatu serius in lucem prodivere, inter quæ præcipue *Monroi Observations on the Structure and Functions of the Nervous System* (1783); *Soemeringi Ueber das Organ der Seele, Königsberg*, 1796; et *Reilii Exercitationes Anatomicæ de Structura Nervorum*, 1797, adnotari merentur."

Prochaska adds, p. 353, "Quis rationem dabit:"..."Quare radices anteriores nervorum spinalium ganglia spinalia insalutata transeant, et quare nam solæ posteriores radices ganglia spinalia trannare cogantur."..."Quare omnium cerebri nervorum solum quintum par post ortum suum more nervorum spinalium ganglion semilunare dictum facere debet, sub quo peculiaris funiculorum fasciculus ad tertium quinti paris ramum maxillarem inferiorem dictum, properat insalutato ganglio semilunari ad similitudinem radicum anteriorum nervorum spinalium?"

Sœmmering has asked similar questions. Sir Charles Bell has quoted Prochaska, and Sœmmering, and Scarpa, in a tone of exultation; but I confess that to me it appears that that justly celebrated physiologist has not approached any nearer to the resolution of these questions than his predecessors. Sir Charles Bell has, I believe, distinctly proved the difference of function between the anterior and posterior spinal nerves—a brilliant discovery, which will, as long as anatomical and physiological science last, perpetuate the memory of his genius; but there is no connexion between the function of sensation and the existence of a ganglion; and the unequivocal sentient nerves, as the olfactory, the optic, the auditory, are without any thing very distinct of this kind.

The questions, then, still remain, why is the portio major of the fifth, especially, and the posterior spinal, nerves provided with ganglia? The reply to these questions, and the argument, may be stated thus:—

1. There is an internal nerve for formation, nutrition, secretion, &c. 2. This nerve is ganglionic. 3. There are external organs and structures requiring nutrition, &c. 4. There are also external ganglionic nerves. The inference is plain, that these constitute the external ganglionic sub system. The fifth especially abounds with ganglia.

It is true that the semilunar and external spinal ganglia differ in appearance from the ganglia of the sympathetic, as Sir Charles Bell has well displayed. What is the nature of this difference? To this question I find no reply in authors. It is plain, however, that the difference consists in their being, alone, *plexic*. The internal ganglionic nerve is purely nutrient; its ganglia are simple. The external involve sentient, and I believe excitory, nerves, with the nutrient; they combine, therefore, the appearances of the plexus and of the ganglion.

I must add another argument upon this point. If the sensation of the face be lost by paralysis, arising from disease of the *brain*, the eye is safe; but if the same event occur from compression or destruction of the *nerve within* the cranium, by disease, or in an experiment, the eye ceases to be nourished, and becomes destroyed! In the former case the nerve of sensation merely has suffered; in the latter the nerve of nutrition, as well as of sensation, has been involved in the disease or injury.

III.—*The Pathology of the Nervous System.*

I now proceed to that part of the subject which it is more peculiarly my province to treat in this place—the pathology of the nervous system.

In order to conceive a clear idea of the pathology, we have only to imagine the physiological phenomena already noticed assuming a pathological character. Now the force of these phenomena may be augmented, or diminished, or annihilated.

In regard to the cerebral functions, we have, in the sentient nerves, pain or insensibility; in the cerebrum itself erroneous perceptions and volitions, or delirium, or a total deficiency of these faculties, or coma; in the motor nerves continual voluntary actions, or paralysis.

We may take the face with its sentient and motor nerves to illustrate a part of this subject. We may have morbid sensibility in the face; and this may assume the form of *tic douloureux*. We may, on the other hand, have loss of sensibility: this may arise from disease of the opposite hemisphere, or of the fifth nerve, within, or without, the cranium. The

former case constitutes hemiplegia of the face; the latter cases have been particularly described by Sig. Bellingeri* and Sir Charles Bell†. We have in these affections interesting calls upon our resources for the diagnosis.

In hemiplegia the loss of sensation is rarely complete, and there is usually paralysis of the muscles of the face, and the susceptibility of the nostrils to irritants is unimpaired; this was the case in a patient whom I recently examined, by the kindness of Dr. Watson, in the Middlesex Hospital.

In the case of disease of the fifth within the cranium, the loss of sensibility is frequently complete, the nostril has also lost its susceptibity to the impression of stimuli, and eventually the eye, not being nourished, shrinks and collapses; the power of the masticatory muscles is impaired, but the face is not distorted by any *apparent* paralysis.

If the seventh or facial nerve be affected, we may have *spasmodic tic*, as represented in this portrait, or paralysis, as represented in this. The patients are drawn attempting to close the eyes. In the case of spasm, it is the eyelid of the *contracted* side of the face which does not close. In the case of paralysis, it is the eye of the *relaxed* side which is reposed: in *both* it is the *affected* side.

Both these affections may have their origin *within* or *without* the cranium. I am at this moment attending a case of spasmodic tic, arising from a cause within the cranium, with Mr. Tyrrell. With the tic there is defective vision of the eye of the side affected. Spasmodic tic arising from causes external to the cranial cavity are not uncommon: this is a slight sketch of such a case, which I had taken from a patient at Bridgewater in 1817.

I will close these hurried remarks by an observation of some interest. In paralysis of the face, from disease of the opposite hemisphere, the eye-lids can be closed, as in this representation;—in paralysis of the facial nerve, the orbicularis is paralysed, as you have already seen in this. What is the rationale of this difference? The seventh, like the fifth, is a compound nerve. As the latter embraces excitor and ganglionic filaments, which are not involved in the attack of hemiplegia, so the former comprises a branch belonging to the excito motory system, which is not affected in disease of the cerebrum. At least such is my view of this subject.

I must not, however, extend my observations on the cerebral system, but hasten to that in which particularly to engage your interest. That I shall readily do this, on account of the part which I have taken in its elucidation, I have no doubt; but I wish particularly to do, on account of the intrinsic and particular value of the subject.

Both the fifth and seventh pairs of nerves are more complex than they are represented to be by Sir Charles Bell. The former includes excitor and nutrient nerves, with the nerve of sensation; and it has appropriate origins, distributions, and offices: of its offices, sensation alone is impaired by cerebral disease; but all are annihilated by the pressure of a tumor within the cranium. The seventh comprises pure cerebral and true spinal nerves: the cerebral only is affected in hemiplegia, and the orbicularis retains its power; all are paralyzed by the pressure of a tumor below the ear, and we have paralysis of the sphincter of the eye-lid. This remark leads me to observe that *ptosis* is a cerebral paralysis, whilst *logophthalmia* is one of the true spinal system: to the latter system *strabismus* also frequently belongs.

The first remark I would make is a very broad one. I believe that the *whole* order of spasmodic and convulsive diseases belongs to this, the excito-motory division of the nervous system,—and that they cannot be understood without a previous accurate knowledge of this system!

A second remark is equally important. All these diseases have their source in *one* of *two* parts of the excito-motory system: the *first* series have their origin in the spinal marrow itself, the axis or centre of the system; I shall designate these cases by the epithet *centric:*—the *second* series have their source in the excitor nerves, consequently at a distance from that centre; I shall denominate them the *eccentric*. I will soon convince you that this distinction is not an unimportant one: the prognosis depends upon it almost entirely; the centric diseases are, for the most part, incurable; the eccentric diseases, on the contrary, as generally, with some particular exceptions, admit of cure. I will briefly illustrate these positions:—You have two little patients with croup-like or other convulsion; one of these cases may arise from disease within the cranium or spinal canal; it will most probably prove incurable: the other may arise from dentition, a cause acting upon an excited branch of the fifth; I need scarcely add that it will generally yield to the prompt and energetic use of the appropriate remedies.

A third remark is, that in all, or almost all, the order of spasmodic diseases, the

---

* Dissertatio Inauguralis, 1818.
† The Nervous System.

parts most immediately concerned in ingestion and egestion,—the orifices and exits of the frame, are those principally affected. The physiology has become pathology. The *larynx* is *closed* in the convulsions of children, in epilepsy, in puerperal convulsion; it is spasmodically affected in tetanus and hydrophobia; it is partially affected in the croup-like convulsion, in hysteria, in which there is frequently loss of voice, &c. The *pharynx* is affected in some of these diseases. The respiratory muscles are so in all. In epilepsy we observe affections of the sphincters, and even of the ejaculators.

No disease can illustrate the pathology of the excito-motory system better than epilepsy. It is sometimes centric, and incurable; frequently eccentric, arising from gastric or intestinal irritations, and curable. It involves every part, and every function, of which I have spoken under the head of the physiology. The fourth and sixth nerves are affected, and the eyes move convulsively; the tongue is protruded, the teeth are forcibly closed upon it, the mouth is variously moved with the extrusion of bloody foam; the larynx is closed, and there are forcible convulsive efforts of the expiratory muscles; and as I have just stated, the sphincters are sometimes relaxed, and the ejaculators occasionally expel the semen.

I must here draw a brief parallel between epilepsy and the act of coitus. Galen designated this act as a slight epilepsy, observing—"Hippocratis verba hæc traduntur;" την συνουσιαν ειναι μικραν επιληψιαν; it has also terminated in actual epilepsy, or, like epilepsy, in cerebral hæmorrhage.

The condition of the larynx and of the respiratory motions affords an important diagnosis between epilepsy and hysteria. In the former the larynx is usually closed with forcible expiratory efforts; in the latter it is open, with heaving, sighing, breathing.

In one case of epilepsy, my patient, who was musical, lost the power of singing the higher notes after each attack. It is well known how frequent loss of voice is in hysteria. In hysteria we have rarely, if ever, a bitten tongue.

A terrible disease of this order is tetanus. All the symptoms of tetanus sometimes arise from disease within the spine. This ought to be termed *centric* tetanus. Far more frequently the cause is seated externally,—in the course of some of the excitor nerves of the system. A nerve included in a ligature, or lacerated in a wound, is most frequently the *eccentric* seat of tetanus. In both cases it is as plain that it is the excito-motory division of the nervous system which is involved in the disease, as is the sun at meridian day.

To show you how little this subject has been understood, I will adduce one fact especially. Even Mr. Swan, than whom no one has dissected the nervous system with more success, imagines that tetanus may have its seat in the ganglionic or sympathetic system of nerves*.

Mr. Swan observes—"I have been induced to inquire how the body is usually affected after accidents. From that inquiry I have been led to state, that when a severe injury has been received, the ganglia of the sympathetic nerves become irritated, and consequently the parts to which they distribute nerves." The irritation "may be communicated to many of the cerebral and all the spinal nerves, and from these to the spinal chord; thus producing tetanic spasms, spasms varying according to the part of the sympathetic nerve most affected, as well as the extent and complexity of the irritation."

It is difficult to conceive how the sympathetic could either be affected by the cause, or produce the symptoms, of tetanus; its functions are interstitial, not obvious to our senses; seen only in their *effects*. It is plain, on the contrary, that the real seat of this disease is that portion of the nervous system which I have distinguished from the rest, and designated the excito-motory. Tetanus may be produced at will in the frog or salamander, by applying strychnine to the skin. If the head be moved, the frame is still tetanic. If any portion of the spine, even the tail, of the salamander be separated, it exhibits all the phenomena of perfect tetanus! These cease on destroying the caudal portion of the spinal marrow, by means of a fine needle. If in the decapitated turtle you lay bare certain nerves, and pinch them continuously with the forceps, you immediately induce a state of tonic contraction of the muscles of all the four extremities, and of the tail. This experiment is the very *type* of tetanus, and leaves *no* doubt what particular part of the nervous system is affected in this disease.

I have not time to say a word about hydrophobia. But consider how this disease is induced; what symptoms present themselves; what parts, what functions, are involved; and you cannot fail to fix upon the particular division of the nervous system affected in this most terrible of maladies.

But I must hasten to conclude. Allow me to say one word respecting vomiting. This act may be excited by disease within

* A Treatise on Diseases and Inquiries of the Nerves, 1834; p. 325, &c.

the cranium, by irritation of the fifth (?) in the fauces,—of the pneumo-gastric in the stomach, the gall-duct, the ureter,—of spinal nerves at the cervix uteri. This familiar phenomenon combines these excitor nerves, and the motor nerves of respiration, into one system.

On the other hand, dentition produced strangury and tenesmus,—symptoms of calculus, in the little boy of a friend of mine, symptoms which ceased on freely lancing the gums.

In one case, extreme spasmodic stricture of the sphincter ani was produced by the unsuspected presence of a calculus in the urethra. There is no more common event than retention of urine from passing a ligature round a hæmorrhoidal tumor. In *all* these various cases an excitor nerve is irritated; the irritation is carried to the medulla oblongata or spinalis, and reflected upon the muscle, or system of muscles, excited to spasmodic action.

The time does not now admit of my adducing more facts of this kind. Before I conclude, however, I must lay before you some facts of another description.

First, disease of the meninges and of the brain induce spasmodic actions. How is this to be explained? I think, upon the principle of *counter-pressure*. In an interesting case most anxiously watched, and accurately detailed to me, by my friend Mr. Toogood, of Bridgewater, of a little girl, aged thirteen months, the croup-like convulsion occurred repeatedly, until one day, when the bones of the cranium separated, the convulsion then ceased. In a case of spina-bifida related to me by Mr. Herbert Evans, of Hampstead, there was a croup-like convulsion whenever the little patient turned, and so pressed upon the tumor. In the case of anencephalous fœtus described by Mr. Lawrence, convulsion was produced on pressing on the medulla oblongata. These and other facts lead me to think that convulsions, arising from cerebral disease, is thus to be explained. Convulsion, in its turn, produces cerebral congestion, and probably effusion.

What is the rationale of convulsion from excessive hæmorrhagy? It struck me that this question might be resolved by experiment. I went to the house of a butcher, and begged to see a sheep killed. The usual mode of doing this is, first to divide the spinal marrow, and then to open the large vessels. At my request, not only the spinal marrow, but the entire neck, was divided, the head being separated from the body with the exception of the skin: the blood-vessels were then divided. I watched the effect of the flow of blood. After a certain hæmorrhagy had taken place, the animal was violently convulsed. This convulsion could only be spinal.

One final word upon the pathology of the external portion of the ganglionic system. I think it probable that many of those cases in which the limb of an infant ceases to grow, are cases in which the disease is seated in the posterior spinal nerves leading to the part—probably at or near their origin. This conjecture must be confirmed by the careful post-mortem examination of such cases. It may possibly admit of being illustrated by experiment.

You will be assisted in your study of the diseases of the nervous system by the Syllabus of these diseases which I have had printed for you. The anatomy, the physiology, the pathology, the individual diseases, the infantile diseases of this system, are pretty fully arranged in it. I shall in future lectures treat of these subjects in their turn, and, as usual, in a perfectly *practical style*, from which the present lecture must be viewed, in some degree, as a deviation.

I *must* now conclude. If I have awakened your attention and interest in reference to this important pathological and practical subject, I have done all that I could expect from a single lecture. I have one request to make of you: receive what I have said in a love of the truth; seek not to dispute, but to prove—to confirm or correct my statements. It is some years since I began my inquiries; much, very much, remains to be done. I trust I shall be aided by *you* in the further prosecution of the subject. Be careful how you observe; remember my words on a former occasion—*fulness*, *accuracy*, *probity*, should be the legible characters written upon every *case*, and the mental and moral characters of every *observer*.

DEATH OF AN INFANT FROM INHALATION OF HOT TURF ASHES.

To the Editor of the Medical Gazette.

SIR,

THE nature of the injury, in the subjoined case, I believe to be very rare. I have no recollection of having met with one like it in the course of my reading, and it is new to those of my professional brethren to whom I have made known the particulars. As such, I transmit it to you for publication, thinking it may prove interesting to your numerous readers. The drawings, sent herewith, which most accurately

illustrate the condition of the parts affected, were done by our assistant, Mr. F. G. Delamotte, of whose skill as an artist honourable mention has been made, both by you and myself, in a former volume of the Gazette.

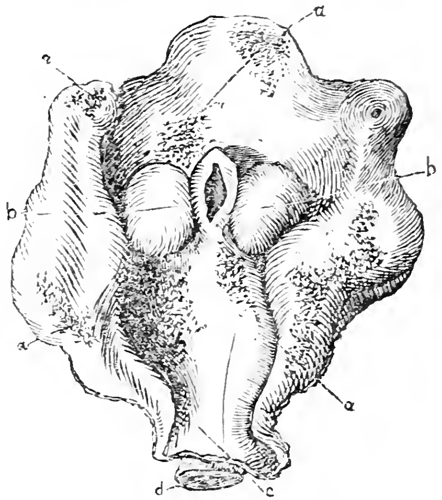

FIG. 1.—*Interior of Pharynx.*

a, a, a, a, Particles of ashes.
b, b, Vesications on each side of rima glottidis.
c, Œsophagus.
d, Trachea.

On the 12th of this month, as I was riding to the house of a gentleman whom I was attending at Seale, I was informed that a child, belonging to the parish, had been severely burnt at Puttenham, about five miles from here; and that a messenger had been sent to request me to come immediately. I reached the house where the child was, at a few minutes after one o'clock, found it had been dead nearly an hour, and that the distressing circumstances attending its death were as follows:—

About eleven of the same morning, the mother had left the child alone, in the only room down stairs which was inhabited, during not more than three minutes, for the purpose of washing some potatoes for her pig, which she did in a back apartment adjoining the room. The child was a very fine boy, 16 months old, unable to walk; but with the assistance of chairs, or any of the furniture in the chamber, to hold by, he could move himself from one place to another. Unfortunately, he was near the fire-place when the mother quitted him; and on her re-entering the room, she saw her poor child lying motionless, with his face on the hearth, which contained a vast quantity of ashes.

The cottagers in this neighbourhood, where heath so much abounds, chiefly use, for firing, the turf-sods collected from the commons or heaths, the ashes of which are very fine, and retain the fire in them longer than those of either coal or wood. Their fire-places are large, occupying the whole space of the bottoms of their huge chimnies, and raised a few inches only above the level of the floor. Thus, owing to the large consumption of this turf, which burns rapidly, an immense amount of ashes often accumulates on the hearth, and in the present instance it is estimated there were not less than two bushels. The child did not, however, fall into the midst of this, but his face was discovered on a part so thin, that the impression thereof was barely distinguishable.

The infant was instantly taken up by the mother, who called one of her neighbours to her aid. He could not cry—indeed, was scarcely able to breathe; and appeared to them to have something in his throat to prevent his breathing more audibly, or his crying. A mixture of oil and milk was poured into his mouth after they had removed the particles of ashes adhering to it, and to the nostrils, but it plainly could not be

swallowed. He lay perfectly still for probably an hour, and respiration was so feeble and slight, that it was perceptible only upon holding a looking-glass before the face. A little after twelve life ceased, without a struggle or the least movement of the body.

The only *external* marks of injury were, a minute vesication on the tip of the nose, and two others on the upper lip.

On the following day I proceeded to examine the body. In the back part of the mouth some particles of ashes were apparent upon separating the jaws, but no signs of lesion of the mucous membrane. My first object was to ascertain the state of the larynx and lower portion of the pharynx, which I accordingly removed from their natural situation by dividing the muscular attachments of the latter from below upwards. In these parts the whole mischief done was most obvious. The lining membrane of the inferior portion of the pharynx was highly inflamed, and covered here and there with ashes; it was also somewhat infiltrated. (*Vide* drawing.) That of the epiglottis might be truly said to be in a state of vesication and infiltration, both on the tracheal and palatine surfaces, and that of the rima glottidis likewise. This latter passage was rendered quite impervious even to air; and from the distended and swollen state of the mucous membrane, its sides approximated in the centre, and resembled two cherries. Both surfaces of the epiglottis were of a deep red colour, and contained ashy matter, which could be traced a little distance down the œsophagus, and on a portion of the cricoid cartilage internally.

No doubt could exist but that the foregoing state of parts was produced by the direct application of the *hot* ashes, which were inhaled by the poor infant in the effort of crying; and it is very singular that these should be so instantly conveyed to the vital parts thus mortally injured, and that none other adjacent structures should exhibit equally severe traces of damage. (*Vide* drawings.)

The trachea and bronchia were filled with a reddish-coloured frothy mucus; and both lungs afforded the appearances of great congestion.

From the above account of the state of the larynx will be explained the symptoms manifested during the very short period the child survived the accident. The chink of the glottis could not have been *perfectly* closed immediately; but still the aperture was insufficient to allow of more than the most slender respiratory process.

Had I been at the first moment upon the spot, the performance of tracheotomy might have prolonged the little sufferer's existence for some hours. I am not sanguine enough to have expected more from it; at least the results of the operation in the cases that may be compared to the foregoing one—those, I mean, caused by receiving boiling water from the spouts of tea-kettles—would lead me to this conclusion.

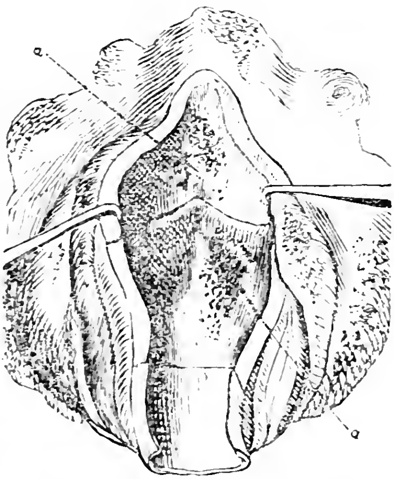

FIG. 2.—*Internal Surface of Larynx exposed.*

a, *a*, Ashes.

Perhaps a certain *honourable* contemporary editor "will not be satisfied" with my conduct relating to the above case, should he now ever read any thing so respectable as your journal. I beg to inform him, therefore, that a coroner's inquest has been held upon the child; and as he has taken such a lively interest in one lately carried on here, wherein I was the medical witness, and in relation to which I have been honoured with his especial insult, and exemplification of literary *candour* (for I do consider it an honour to be insulted and abused by such a character), that he means to move, "in his place" in the house, "on the re-assembling of Parliament," for a *verbatim* transcript of my deposition of the verdict of the jury. I would take the liberty of re-

commending to him, in order to save time, trouble, and expense to the nation, to make a motion at the same time for the like copies connected with the present inquest. No doubt some "innocent" person would here also be found implicated by me, if he would but "manfully" come forward on the occasion with just *twenty-two* misstatements at his back, *Anglicè* falsehoods, half of which must of course be fathered upon the inventive faculties of the *unfortunate* printers (I mean no allusion to the recent *bankruptcy*).

I remain, sir,
Your obedient servant,
G. Bury.

Farnham, Dec. 17, 1835.

ON THE

AVERAGE DURATION OF LIFE,

AND THE

VIE PROBABLE, IN THE SEVERAL COUNTIES OF ENGLAND.

To the Editor of the Medical Gazette.

Sir,

Perhaps you may have remarked that in my last letter I did not attribute an annual rate of mortality to any of the counties of England, thereby avoiding the customary but unsatisfactory manner of so doing without reference to the increase of population,—a fallacy which could not have escaped the notice of the most incurious observer, had he adverted to the well-known fact, that human life is most precarious at its two extremes—in infancy and in old age; so that a rapidly-increasing population (which infers the existence of many infants and their deaths in like proportion), produces a preponderance of mortality in infancy; a slowly-increasing or stationary population (which infers a large proportion of aged persons), produces a similar preponderance in old age; and I still fear that until the effect of these counteracting influences shall have been generally recognized and understood, the facility of dividing an existing population by the annual number of deaths, will continue to produce formal statements and inferences of much less value than has hitherto been ascribed to them.

Another method of estimating the comparative health of nations, was afterwards introduced by those who bestowed on it the title of *vie probable*,—a commodious phrase for expressing the number of years at which one half of the population are dead, the other half survives. But the incompetency of this *vie probable* for its purpose was not concealed by so powerful a counteracting influence, the large proportion of births, and consequently of infant deaths, in an increasing population, producing an overwhelming result, which puts to flight the *vie probable* as an absolute measure of health and longevity.

A third and better method for approximating to the same kind of knowledge, has been devised and explained by those who have given it the title of *vie moyenne*, which is found by collecting the number of years during which all the deceased have lived, and dividing the total by the number of the deceased. Thus is ascertained the average duration of life, which would be equivalent to what is called in England "the expectation of life at birth," were it not that the *vie moyenne* is influenced by the increase of population, while "the expectation of life," being ascertained by pursuing the same individuals through life, is not liable to variation otherwise than from an actual variation in the duration of human life, which has been much prolonged since the ages of the deceased were first recorded.

According to the unquestionable theorem of Laplace, "Le nombre d'années qui exprime la durée moyenne de la vie est le vrai rapport de la population aux naissances. La détermination de ce facteur est le point le plus délicat et le plus intéressant des statistiques vitales." In other words, the *vie moyenne* indicates the annual proportion of births (and therefore of deaths), supposing the population to be stationary, or rather to have been retrospectively stationary, through the life of man: a condition which probably has never been fulfilled—certainly has never been known to have occurred; which amounts to the same obstacle in practice. And it is to be understood that an increasing population will always exhibit a *vie moyenne* shorter than the true expectation of life, a decreasing population having an opposite tendency. Thus in England it has been sufficiently ascertained that the expectation of life at birth is at present (combining the sexes) about forty years; whereas the highest amount of the *vie moyenne*, calculated upon the

deaths of 18 years (1813-1830), little exceeds 40 years in any county, and in the other extreme is no more than 25 years.

Knowing by experience how difficult it is to explain in words the effect of increasing population on the *vie probable* and the *vie moyenne*, I shall take the liberty of exhibiting a *scale of coincidence*, founded on the fact, that an increase of 57 per cent. in 30 years (1801—1831), has produced in England a *vie probable* of 25·4 years, while a less increase of about 20 per cent. in some of the counties has left to them a *vie probable* of 40 years; which agrees well enough with a difference of ·4 (four-tenths of a year) for 1 per cent. increase of population.

The *vie moyenne* of England I have calculated at 33 years, which in like manner becomes 40 years in some of the counties, agreeing with ·2 (two-tenths of a year) for 1 per cent. increase of population; which in both cases is carried on to 99 per cent., up to which, from 19 per cent. increase, the annexed scale is necessary for including the several counties. It is compressed or abbreviated by omitting the numbers which do not apply to the increase of population in any of them.

SCALE OF COINCIDENCE

Of the Vie probable, *and of the* Vie moyenne, *with the Increase of Population.*

Per Centage Increase.	Vie Probable.	Vie Moyenne.	Per Centage Increase.	Vie Probable.	Vie Moyenne.	Per Centage Increase.	Vie Probable.	Vie Moyenne.
0	49·2	44·4	37	33·4	37	59	24·6	32·6
1	47·8	44·2	38	33	36·8	60	24·2	32·4
2	47·4	44	40	32·2	36·4	61	23·8	32·2
7	45·4	43	41	31·8	36·2	62	23·4	32
12	43·4	42	42	31·1	36	64	22·6	31·6
17	41·4	41	43	31	35·8	67	21·4	31
19	40·6	40·6	44	30·6	35·6	72	19·4	30
21	39·8	40·2	45	30·2	35·4	73	19	29·8
22	39·4	40	47	29·4	35	74	18·6	29·6
25	38·2	39·4	48	29	34·8	77	17·4	29
27	37·4	39	50	28·2	34·4	81	15·8	28·2
29	36·6	38·6	52	27·4	34	82	15·4	28
32	35·4	38	55	26·2	33·4	87	13·4	27
33	35	37·8	56	25·8	33·2	92	11·4	26
36	33·8	37·2	57	25·4	33	97	9·4	25
						99	8·6	24·4

It is proper to guard your readers against expecting perfect accuracy in the application of this scale; evidently the *plus* and *minus* of longevity in different situations is a disturbing element; and more powerful than this (as being generally applicable) is another consideration—that the collected deaths extending from 1813 to 1830, apply in strictness to a middle point, to the enumeration of May or June 1821; and it is only from the equable march of population since that time and previously to it (about 15 or 16 per cent. in each of the three decennial periods), that we are justified in applying the foregoing scale to the increase of the entire 30 years *. One-half of the inhabitants of England are not above 20 years of age—two-thirds are not above 30 years of age; so that one-third of the existing population (all above 30 years old) were born previously to the enumeration of 1801, when the increase was proceeding at a lower ratio by one-half. Of this the scale can take no cognizance; and in the counties which have increased equally in the entire thirty years, the increase has not always occurred in regular gradation. Thus, in the counties of Berks and Salop, which have equally increased 33 per cent. in population between 1801 to 1831, the three decennial periods shew an increase as 8, 12, 10, in the former—as 16, 6, 8, in the latter; which cannot but have produced discrepancy in the ages of those who die. Expecting fair allowance for all these recited obstacles to accuracy of result, I have ventured to construct the following table:—

* The increase of females (far the best criterion) has been as 14·15—15·71—15·46—in the three decennial periods.

TABLE *exhibiting* (1.) *the Increase of Population* (1801—1831) *in England and Wales, and in the several English Counties;* (2.) *the* Vie probable, *or Age at which One Half of the Population were dead* (1813—1830); (3.) *the* Vie moyenne, *or Average Duration of Life* (1813—1830), *with the Difference in both Cases from the foregoing* Scale of Coincidence; (4.) *lastly, the Annual Mortality* (1816—1820), *one-tenth being here added, in compensation for the usual Rate of omitted Entry in Parish Registers.*

Isle of Ely	64	13·8	— 8·8	27·9	— 3·7	43

It will be perceived that I have added the Isle of Ely at the bottom of the foregoing table; this district is distinguished from the rest of the county of Cambridge by a peculiar jurisdiction, and very unfavourably as regards health and longevity. It is highly fertile, but flat, alluvial, and marshy; and containing a population of 46,000 inhabitants, furnishes a fair specimen of the effect of marsh land, and will partly explain the foregoing table. To your medical readers it may be superfluous to remark, that every surface retentive of water differs only in degree from fenny, or marsh land, in its deleterious effect on human health; so that to the under-ground drainage of arable land may be attributed much of the increased longevity which has occurred in England, beginning with the year 1785. This wholesome process was vastly increased from 1795 to 1815, in consequence of the high price of corn, till the end of the war. The Western half of the County of Suffolk (commonly called *High Suffolk*) is a prominent instance of the benefit of Under-ground drainage, as conducive to health, as well as insuring fertility.

It will be understood that the entire of England cannot but represent the average longevity of all its counties, and this is denoted in the table by the word *nil*, signifying *no variation* from such average; which is, in fact, the foundation of the whole calculation of *plus* and *minus*. Next above ENGLAND (in column 3) stands Kent; which county having increased 56 per cent., ought, according to the scale of coincidence, to give *vie moyenne* 33·2 years, while, in fact, it gives no more than 31·5, less by 1·7 than the average longevity of England, if the scale be correct; and Kent being a county bordered on its northern limit by much marsh land (especially at the mouth of the river Medway), and containing Romney marsh on its south coast, the longevity of the entire county is thus depressed below average. The same defect, from the same cause and in a greater degree, affects the county of Essex; and all the counties bordering the Isle of Ely manifest some depression. Next below ENGLAND (in column 3) stands Durham; which county having increased 59 per cent., ought to give *vie moyenne* 32·6 years, but, in fact, gives 34·6; so that it may be deemed healthy above average, to an extent measured by the difference of these numbers.

The excessive cases are Ely, already described as remarkably unhealthy, and in the other extreme Cornwall, a county well defined on the north and south by the sea, and in character opposed to Ely, as consisting of a middle ridge of high land, sloping on both sides with uneven surface, to the north and south coasts; which are no where flat, much less marshy. A great quantity of rain falls in this county, nearly twice as much as in London *, but the soil is not retentive, and water never stagnates on its surface. With these favourable characteristics, Cornwall shows a longevity of five years above the average deducible from its per centage increase, in like manner as Ely declines three and a half years below such average.

The seeming longevity of Sussex is liable to subtraction, because its population has been much increased by the immigration of adults, who have settled at Brighton, Hastings, and other places of fashionable resort on the coast. Surrey has experienced a similar immigration, in a greater degree, from its containing the south suburb of the metropolis, where the parishes of Lambeth, Newington, and Camberwell, have enormously increased in population. I need not repeat that infant mortality reduces the *vie moyenne*, nor say that *therefore* immigration has an opposite tendency.

The whole table contains forty-two counties, or parts of counties. In nine of these the difference of the actual *vie moyenne* from the scale of coincidence, does not exceed six months; in eight others, from that to twelve months; in twelve, from that to eighteen months; and in six, from that to two years: the rest have been already specially noticed. These are, indeed, considerable variation as is the difference of longevity in various situations; and for due appreciation of the scale of coincidence, they are to be contrasted with the negation of any such scale; in which case the *vie moyenne* of West York, at twenty-nine years, must be compared with that of North York at forty years; these being parts of the same county, and in contact along a border of seventy miles in extent. So the results of Rutland, North York, and Hereford, which average at 40 years, are, on that supposition, to be deemed compatible with the

* At Penzance, 44·7 inches; in London, 25 inches. See "The Medical Topography of Cornwall," for this and other particulars, by Dr. Forbes.

vie moyenne of Lancashire at $25\frac{1}{2}$ years; which would infer a different race of beings, rather than different counties in the same England; and, in favour of the scale, it must not be forgotten that it is supported by no larger basis than the known increase of thirty years. In the year 1841, it may be constructed with the advantage of ten years' additional basis; when three-fourths, instead of two-thirds, of the population will have been born after the enumeration of 1801.

I shall now advert to the *vie probable* (which occupies column 2 of the table, and enhances the difficulty of withholding assent to it.) Herein the average *vie probable* of England is calculated at 25·4 years, and, being marked by the word *nil*, is the origin of a range of variation from it which extends twice as far as that of the *vie moyenne*—to thirty-two years instead of sixteen years. Consequently the difference from scale is usually double in the several counties: in some it is widely different from this, especially in Middlesex (which is much the same as the metropolis); a fact which I cannot pretend to explain, the relative amount of difference between the *vie moyenne* and the *vie probable* never having been (to my knowledge) investigated; and I can furnish nothing more than the facts which appear in the table. Not only is the effect of infant mortality very manifest in calculating the *vie probable*, but the greater number and great mortality of male infants create a very perceptible sexual variation of result. "This cause is so powerful, that in Lancashire, where one-half of all individuals born do not attain the age of twelve years, one-half of the males are dead at seven years, one half of the females at sixteen or seventeen years of age."—(Population Preface, p. xlvi.)

The last column (4) of the table, exhibits the annual rate of mortality in the several counties; and perhaps it may be remembered that in my last letter this was omitted: whereby I avoided this usual comparison of the annual number of deaths with the existing population, until I could show at the same time the fallacy already mentioned, of so doing without reference to the increase of population. In fact, the annual rate cannot be computed at less expense of labour than a calculation of the law of mortality throughout human life in each county; nor would the result of such labour be satisfactory, or indeed valuable, considering the familiar, the daily, migration of individuals from one county to another.

I have heretofore had occasion to notice the difficulty of obtaining an accurate knowledge of the first year of life*, in which, according to the most probable accounts, more than one-sixth (18 per cent.) of male infants—more than one-seventh (15 per cent.) of female infants—usually perish. This granted, the annual rate of mortality of Males in England and Wales is less than one in forty (40·5), their maximum expectation of life occurring at four years of age, and being then nearly fifty years; one-half of them attain to the age (*vie probable*) of 43·5 years. The annual rate of mortality of females is one in 44 (43·7); their maximum expectation of life, which is not less than fifty-three years, occurs at three years of age. One-half of them attain to the age (*vie probable*) of forty-eight and a half years. The expectation of life of the two sexes conjointly is very nearly forty-two years at birth; which also represents the annual mortality of England to be as one in forty-two, were the population stationary.

I should commit a crime, or, at least, be guilty of a grievous defect in my endeavour to convey knowledge to your readers, if I left those who may refer to the tables of English mortality, which you inserted in your 16th volume (p. 585), at a loss to understand why the expectation of life there given differs half a year (as 39·96 to 40·5 in male life; as 43·2 to 43·7 in female life) from what is here stated. The distinction is, in truth, somewhat technical between the expectation of life *at birth and under one year*: the last phrase always meaning the middle of that year; because some begin to live in the first day of every year, some in the last day; wherefore the age of an individual is always assumed by deducting one half year from his next birth-day. This, indeed, is not strictly true, especially in the first year of life, because many more die in the first months of their life than in the rest of the first year. This is an anomaly difficult to be overcome; and the second year partakes of the same obstacle. In fact, the best calculators are so little in unison as to the first year of life, that in the tables of M. Quetelet, which you have inserted (vol. xv. page

* Med. Gaz. vol. xvi. p. 272.

599), the expectation of life at birth is stated at 26, 24, and 20 years, in England, Belgium, and France, respectively*. Yet all these are raised, and with sufficient coincidence, to about forty years' expectation in the next year; and from five to sixty years of age differ no more than English counties differ from each other; and considering that few insurances or other contingencies rely on a life younger than five years, or above sixty years, the expectation of life is sufficiently established for practical purposes; the same result as from stationary population being attained by the official necessity of watching the termination of every life enrolled in the Government Annuity-Office, and the Equitable Assurance, to an amount (already stated) of 30,000 deaths. Previously to the life-annuity labours of Mr. Finlaison, and the publication of the experience of the Equitable Assurance-Office, nothing really authentic existed, unless we may except the earliest and best work on the subject, by Mr. Kerseboom (published 1742), whose materials commence in the year 1615. A reprint of this very scarce book, or rather a translation of it into French or English, is a great desideratum, and, with such notes as might now be appended from more modern experience, would form a most valuable addition to what Laplace has well named *Statistiques vitales.* The essay of M. Deparcieux (also constructed on government annuities), *Sur les probabilités de la durée de la vie humaine*, is as good as could be produced from his materials; but these were not sufficiently distinct to confer much permanent value on the results†.

I must now be permitted to recur to the *Scale of coincidence*, which appears in a former part of this letter, because the *vie moyenne* therein becomes 44·4 years, supposing no increase of population to have occurred; whereas the expectation of life at birth, which ought to be the same, has since been stated at forty-two years, and of course (according to Laplace), the rate of annual mortality would in that case also be as one in forty-two. I do not undertake to reconcile this discrepancy, which, indeed, would be to affirm, and even to warrant, the accuracy of a scale merely tentative and suppositious, in so far as it transgresses the limit of experience. This limit occurs at about 20 per cent. increase of population, according to the table of English counties, and short of this increase the table is purely inferential; nor does it follow from these two or three approximations, that the *vie moyenne* must proceed to *zero* in a regular arithmetical ratio, as assumed in the scale. If the *zero* denoting stationary population stood opposite to forty-two years *vie probable*, as well as forty-two years *vie moyenne*, the congruity would be satisfactory; but I have already said that nothing certain has been theoretically established, as to the limit or progressive ratio of the *vie probable.* Examples of its result in two instances appear in a small pamphlet of much value, by Sir F. D'Ivernois, *Sur le mouvement de la population de deux paroisses de Suisse*: in which the following particulars are worthy of attention.

The parish of *Montreux* appears to have increased in population 25 per cent. in about sixty or sixty-five years, say 10 per cent. from 1801 to 1830. The number of inhabitants was 2833 at the last of these dates. The *vie probable* was thirty-nine in the year 1765, as computed from the ages of the deceased during the ten or eleven preceding years. The *vie moyenne* was then found to be thirty-six years. Similar computations from the same parish register give fifty-five years *vie probable*, forty-five years *vie moyenne*, for the first ten years of the present century.

The other Swiss parish, *Leysin* (also in the Pay de Vaud), has increased in population from 405 to 447 inhabitants (about 10 per cent.) in 80 years. In the middle of the last century, its *vie probable* was 61 years, now calculated at 64 years; its *vie moyenne* was 50 years, and is now 56 years.

M. D'Ivernois blames, as an inexcusable negligence in the last enumeration of the inhabitants of the Pay de Vaud, that their ages were not ascertained; but as he also says the sexes were not distinguished, which is indeed an unaccountable omission, how could he expect the inquiry to be extended to the age of every individual, which is in

---

* In the tables appended to Mr. Milne's Treatise on the Valuation of Annuities, the expectation of life at Carlisle is stated to be 38·72 at birth; 44·68 in the next year. In Sweden to be 33·12 at birth, 44·11 in the next year. In France, according to M. Duvillard, 28·76, and 36·35; but the basis of this last computation is unknown.—See Milne's Treatise, § 855, § 859.

† See Mr. Milne's Treatise, § 865, § 868.

truth a labour of some detail? True, indeed, as regards the value of these *Lilliputian* observations on two parishes (as he modestly designates them), the omission is somewhat vexatious, as the seeming miracle of health and longevity might entirely disappear, if we had opportunity of comparing the mortality of each grade of life with the total number of individuals existing in the same grade *. For explanation of the phenomenon, we are thus driven to conjecture that from some peculiar or local cause, the youth of these alpine parishes have recourse to temporary migration, and return to spend their old age at home (as a hunted hare to her remembered seat), after the fatigues of an active life. But setting aside this supposition, the paucity of children born at these places, which seems to be rated little higher than one in fifty of the population annually, cannot but raise the average duration of life to a high figure; and if this paucity arises from the cause which limits the fecundity of 100 marriages at Geneva to 275 births, the parents of children thus prudentially restricted in number, will always be able and willing to exert the greatest care in the preservation of every child to adolescence; and as the mortality of such children may thus be diminished one-half, the *vie probable* and *vie moyenne* may consistently and actually be exalted to the high figures which are recorded in this remarkable pamphlet. I shall not advert further to it, than to infer from these examples, in which the *vie probable* exceeds the *vie moyenne*, that the same result will always be found if authentic instances shall hereafter be obtained of the particulars of any decreasing population on a large scale.

I entirely agree with M. D'Ivernois in the importance of ascertaining the ages of the living as well as of the deceased; and if this inquiry was not repeated in England in the year 1831, the omission was comparatively immaterial, because the known ages of persons existing in the year 1821 were best applicable to the ages of the deceased from 1813 to 1830; and further, because the only machinery which can be employed in enumerating English population would have been overburthened in 1831, had the extensive inquiry then made into *occupations* been accompanied with a demand for the ages of individuals. I venture to think and to hope that no such obstacle will occur in the year 1841; in which case the number of children under one year, and between one and two years of age, may be asked, and the difficult question of infant mortality in some degree illustrated.

The more I have been led to reflect on the influence of increasing population, and of the results which may be anticipated from ascertaining its progress and amount, the more importance I attach to the inquiry, as one which may enable us hereafter to decide from the ages (the grades of age) of the existing population of any nation, the ratio and amount of its increase retrospectively during seventy or eighty years; that is, as far backwards as leaves a competent number of individuals alive at those advanced ages; and thus as years roll on, statistical knowledge will acquire a continuity which time only can bestow, and which will greatly increase its value.

In the meantime examples worthy of notice may perhaps be drawn from the several English counties—that is, by a more accurate investigation of the parish registers during the last century; for it should be understood, that from imperfect knowledge of parish registers at the time of collecting the returns in 1801, many omissions unavoidably occurred in the several counties; but as the deficient returns were afterwards obtained and placed in a supplement, the entire of England became respectably complete; not so the several counties, from a comparison of which with each other, much may be expected; and I am persuaded that a calm revision of the original Parish Register Returns of 1801 (which are safely preserved), will throw new light upon the subject, because many of the returns for the last century were defective, especially in the early part of it, which defects could not be accurately weighed in the formation of the abstract of 1801; but the inquiry of 1831, by which was obtained a complete list of all parish register-books now extant, furnishes the requisite knowledge, especially from 1754 (the date of the Marriage Act), which goes far back into the life of the oldest persons now in existence. I shall therefore apply myself to this task, if permitted (as I doubt not) by competent autho-

* For a decisive illustration of this kind relative to the mortality of North York and West York, see vol. xvi. pp. 270-271.

rity; and shall deem myself well rewarded in applying to a modern purpose of useful knowledge materials unattainable elsewhere in competent extent, and of such unsuspected authenticity as are the parish registers of England.

I remain, sir,
Your most obedient servant,
JOHN RICKMAN.

January, 1836.

SECOND

REPORT OF CASES TREATED IN ST. GEORGE'S HOSPITAL,

(*Being from July* 1, 1835, *to Jan.* 1, 1836);

WITH

"ROUGH LEAVES" FROM HIS CASE BOOK.

By R. MACLEOD, M.D.

ON the 1st of July, 1835, there were in the hospital, under my care, 26 patients. There have since been admitted 106, giving a total of 132.

Of the above cases there have been disposed of	100
Results unknown*	9
Remained under treatment January 1, 1836	23
Total	132

The 100 "disposed of" are as follow:—

Discharged cured	69
——— relieved	8
——— without relief	7
——— for misconduct	1
Transferred to the care of others	3
Removed by relations	1
Dead	11
Total	100

The deaths were produced by the following diseases:—

Organic diseases of the heart, with dropsy	3
Pericarditis	1
Phthisis	2
Bronchitis	1
Tuberculated liver, with ascites	1
Encephaloid disease of liver	1
Abscess in cerebellum	1
Fever	1
Total	11

* Owing to the cases not having been regularly kept, during a short period when I was absent from London.

Deducting from the total 132 the seven of whose cases I have but incomplete notes, and the three which were "transferred," there remain 122, which are accounted for as follows:—

CEREBRAL DISEASES—8.

Apoplexy, with hemiplegia, 1.—Under treatment, convalescent, 1.
Hemiplegia, 1.—Relieved, 1.
Active determination to brain, 1.—Cured, 1.
Chronic disease (organic?) of brain, 1.—Stationary, 1.
Epilepsy, 1.—Stationary, 1.
Mania, 2.—Cured, 1; relieved, 1.
Abscess of cerebellum, 1.—Dead, 1.

SPINAL DISEASES—2.

Paraplegia, 2.—Discharged without relief, 1; under treatment, convalescent, 1.

VARIOUS NERVOUS DISEASES—7.

Chorea, 2.—Cured, 1; under treatment, convalescent, 1.
Hysteria, 3:—

Prominent symptom, palpitation	1
——— pain of left side	1
——— globus	1

Cured, 3.

Paralysis of arms from lead, 2.—Relieved, 1; discharged for misconduct, 1.

Very little has occurred in connexion with the diseases of the nervous system which is worthy of being recorded. In the case of paraplegia, as well as that of partial paralysis of the forearm resulting from the poison of lead, strychnia, pushed to such extent as to produce decided constitutional effects, had no favourable influence whatever on the disease; and this corresponds with almost all the trials I have made of the remedy; so that I cannot venture to say I have ever seen it unequivocally serviceable.

The cases of chorea suggest the remark that although carbonate of iron generally proves successful, yet I have seen several instances wherein it has failed to cure the disease within a reasonable time, even when given in large doses. When this happens I have recourse to the *liquor arsenicalis*, and with invariable, or almost invariable, success. An illustration of this occurred in one of the cases included in the above return; but as it was given in a former number of your journal, I shall not make farther reference to it here. (See case of Ann Gelling, Med. Gaz. Nov. 21, 1835, page 285.) The shower-bath is well known

to be a powerful auxiliary remedy, but its good effects may be partially or entirely prevented where the child is very much afraid of it. This occurred in a little boy at present in the hospital, who became decidedly worse immediately after the use of the bath; so much so, indeed, as to render it necessary to discontinue it after a few trials.

Several interesting points of inquiry are suggested by the case of abscess in the cerebellum discharging through the ear, but as these also have already been briefly touched upon, (Gazette, Oct. 31, p. 157), I refrain from entering upon the subject here.

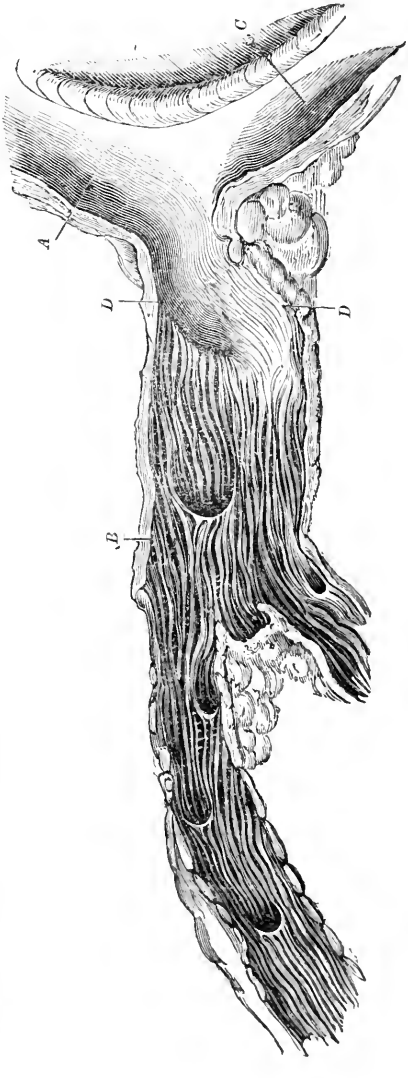
DISEASES OF THE RESPIRATORY ORGANS—18.

Chronic disease (tubercular?) of the larynx, 2.—Discharged without relief, 1; removed by relations, 1.
Phthisis, 8.—Dead, 2; relieved, 3; under treatment, 3.
Hæmoptysis, 2.—Cured, 2.
Bronchitis, 3.—Dead, 1; convalescent, 1.; Cured, 1.
Pleuritis, 1.—Cured, 1.
Pulmonitis, 2.—Cured, 2.

DISEASES OF THE HEART AND ITS INVESTMENTS—11.

Acute pericarditis (rheumatic), 4.—Dead, 1; cured, 2; convalescent (since cured), 1.
Organic disease, without dropsy, 2.—Relieved, 1; under treatment, 1.
Ditto, with dropsy, 5.—Dead, 3; cured (as regards the dropsy), 2.

The fatal case of bronchitis occurred in a man 55 years of age, who had been subject to repeated attacks of cough, with expectoration, which had latterly become complicated with anasarca. He was brought into the hospital for an aggravation of his habitual symptoms, or rather for a more acute attack supervening upon the chronic disease. The air could be heard entering the lungs pretty freely, but with a peculiar sibilus universally, except over the larger bronchi, in which situations there was a hoarser rhonchus. The expectoration was extremely scanty, and consisted of very tenacious mucus. On opening the body the mucous membrane of the trachea presented nothing remarkable, but just below the bifurcation, and into the minutest ramifications which could be traced, it was thickened, and formed prominent plaits or folds running longitudinally, with narrow interstices. The air tubes contained very little mucus. Some idea of the appearance may be gathered from the accompanying engraving, made from a drawing, which my colleague Dr. Hope had the goodness to execute for me.



A, the trachea.
B, the right bronchus.
C, the left ditto.
D, points at which the striæ of the mucous membrane commenced.

The case entered as rheumatic pericarditis, which proved fatal, was one in which the attack supervened upon old disease of the heart, the chief point of interest consisting in the state of the semilunar valves. I subjoin the case.

Case in which the Semilunar Valves were perforated.

Margaret Collard, ætat. 24, admitted December 23, 1835. Had been frequently subject to rheumatism, an acute attack of which had commenced about a week previously. The prominent symptoms were—great anxiety; pain in the region of the heart, with rapid tumultuous action of the organ, and a loud bellows sound. She was bled twice to ℥xii. (viz. on the 23d and 24th), and took large doses of calomel and opium. She died on the 26th, and the body was examined next day.

The pericardium was every where glued to the heart by firm adhesions, which had every appearance of being ancient; but the membrane covering the left ventricle, particularly towards its base, was minutely injected, and seemed soft and pulpy, as from recent inflammation. The heart was of the natural size; the semilunar valves, both pulmonary and aortic, but particularly the latter, were remarkably attenuated. The half of each valve next the free edge was as thin and transparent as the finest membrane; and two of the aortic valves had numerous (five or six) perforations close to the margin, giving it the appearance of a kind of net-work: the thin portion terminated abruptly by a line running across the middle of the valve, dividing it into two parts, that next the vessel having the usual appearance; that next the margin having the aspect above mentioned. Only one corpus aurantii was present; it existed in one of the aortic valves, and was placed in the centre, not at the edge. The mitral valves were much thickened, and one of them particularly shortened, as if a portion of it had been glued to the parts adjacent.

DISEASES OF THE FAUCES—3.

Ulceration (syphilitic), 2.—Cured, 2.
Cynanche tonsillaris, 1.—Cured, 1.

DISEASES OF THE ABDOMINAL VISCERA—24.

Chronic muco-gastritis, 3.—Cured, 3.
Indigestion (functional), 3.—Cured, 3.
Ditto (from organic disease), 2.—Stationary, 1; under treatment, 1.
Hæmatemesis (from disease of stomach?) 1.—Under treatment, 1.
Enteritis, 1.—Cured, 1.
Diarrhœa, 2.—Cured, 2.
Chronic disease of bowels following fever (ulceration?), 1.—Cured, 1.
Colica pictonum, 2.—Cured, 2.
Hepatitis (chronic), 2.—Cured, 2.
Encephaloid liver, 1.—Dead, 1.
Organic disease of liver, with dropsy, 3.—Cured, 1; dead, 1; under treatment, 1.
Abdominal tumors, nature not ascertained, 2.—Stationary, 2.
Kidney, disease of, with dropsy, 1.—Convalescent (as regards the dropsy), 1.

DISEASES OF UTERINE SYSTEM—4.

Leucorrhœa, 1.—Cured, 1.
Amenorrhœa, with various hysterical symptoms, 2.—Cured, 2.
Ditto, with hæmatemesis, 1.—Cured, 1.

In connexion with the above list, which includes diseases of the stomach, I may introduce an—

Additional Note regarding Kreosote.

In my last report, published in July, I stated that I had tried Kreosote in several cases of vomiting, and that the result of my experience led me "to regard it as of doubtful efficacy." More extended observation has not induced me to change this opinion, and I am now quite satisfied that its powers have been greatly overrated, and that it is inferior to hydrocyanic acid in allaying morbid irritability of the stomach. Almost immediately after the appearance of my former paper an account was published of cases treated at the North London Hospital by Dr. Elliotson, from which it would appear that the success of the Kreosote there, was very different from what it had been at St. George's. I can only say that I have fairly, and without prejudice, given the result of what I have seen, and have to regret that in my hands the remedy has not proved equally successful. It answered best in hysterical patients, in whom nausea and vomiting supervened; but as in such cases the symptoms are apt to come on and to subside suddenly, it is sometimes difficult to decide whether their cessation can fairly be attributed to our medicines. Where relief was afforded, this usually resulted from small doses; at least, if four, or at most six drops, did not answer the purpose, I have very rarely seen any benefit from three times that quantity.

In my former notice I pointed out an effect of kreosote not previously described, namely, that of communicating a blackish colour to the urine.

In a postscript to his paper, dated *August*, Dr. Elliotson adverts to the same circumstance as a phenomenon which had been mentioned to him, but which it is evident, from his mode of expressing himself, he had not seen. As no reference is made in either of the above papers to my former "Note regarding Kreosote," the appearance of the cases treated at the North London Hospital, and of the postscript to Dr. Elliotson's paper, the month after my paper was published, must of course be regarded merely as singular coincidences.

FEVERS—6.

Intermittent (tertian), 1.—Cured, 1.
Continued, 5.—Cured, 4; dead, 1.

In the case of fever which proved fatal, the disease was already far advanced before the patient was admitted; and the ileum was found, after death, to be ulcerated.

EXANTHEMATA—4.

Variola (severe, after vaccination), 1.—Sent to Small-pox Hospital, 1.
Scarlatina, 2.—Cured, 2.
Erysipelas (of face), 1.—Cured, 1.

CHRONIC DISEASES OF SKIN—3.

Impetigo, 1.—Cured, 1.
Lepra, 1.—Cured, 1.
Syphilitic eruption, 1.—Under treatment, 1.

RHEUMATISM—30.

Acute (without symptoms referrible to the heart), 10.—Cured, 6; convalescent (since cured), 4.
Chronic, 9.—Cured, 5; relieved, 2; convalescent, 2.
Chronic pain of various joints, with thickening of parts, 5.—Cured, 3; convalescent, 2.
Gonorrhœal rheumatism, 2.—Cured, 2.

DROPSIES, NOT APPARENTLY CONNECTED WITH ORGANIC DISEASE—4.

Œdema (more or less general) from exposure to cold, 4.—Cured, 4.

Bleeding in Acute Rheumatism.

I presume that most practitioners are in the habit of abstracting blood in cases of acute rheumatism, but so far as my observation has extended, the depletion is practised on principles very different from those which are acknowledged in regard to other inflammatory diseases. I mean, either that the bleeding is looked upon only as favouring the operation of certain remedies which are to follow, or at all events as a means which may moderate, but cannot be expected to *extinguish* the rheumatism, and which therefore requires to be aided by certain routine prescriptions. The more I see of rheumatism *in its acute form*, the more am I disposed to think that it is amenable to the same laws as other inflammations; and the object of the present remarks is very briefly to direct attention to this point.

When an attempt is made to argue that rheumatism ought to be treated like other inflammations, the most common answer is, that it is a "specific" disease; and by this all its peculiarities as to pathology and treatment are supposed to be accounted for. But I suspect that this expression is often used rather loosely, and without any very *specific* meaning. If it be intended to intimate that rheumatism is not identical in its phenomena with various other inflammations, it is very true; but the same thing holds good equally with regard to the inflammations of many other textures, as well as of those implicated in rheumatism. Pleuritis is manifested by different general symptoms and different organic changes from bronchitis; and pulmonitis is in those respects different from either. Inflammation of skin differs from that of cellular tissue; that of veins, from both. Why, then, should we think it necessary, in the case of rheumatism, to seek for any other causes to explain its peculiarities different from those which we admit as explanations of the analogous peculiarities observable in the inflammations above enumerated? I say, that the difference between the inflammation of the fibrous and synovial textures in rheumatism, and that of any other texture which may be assumed as a standard of comparison, is not greater than between such standard and various other inflammations which might be named. Again, if by "specific" be meant that there is any thing in the exciting cause of the disease different from that of other inflammations, there is obviously no ground for the assumption: atmospheric vicissitudes give rise to rheumatism or pleurisy, or ophthalmia, and are not more unequivocally the origin of one of these than of another. With syphilis, and other really *specific* inflammations, the case is very different.

Then, as to the terminations of rheu-

matism, in what do they differ from those of other inflammations that may not be reasonably attributed to the peculiarities of structure? We have pain, heat, swelling, and redness, ending in effusion; and this effusion may either be absorbed or become organized, just as in other inflammations. And further, rheumatism may, and (I conceive more frequently than many suspect) does, go on to other and more formidable terminations, particularly that in suppuration. I have recently seen two instances of this kind, in which several joints were simultaneously attacked with pain, swelling, redness, and all the ordinary symptoms of acute rheumatism. The disease was treated as such, and the affection of several of the joints subdued, but in one case it remained persistent in the hip, and in another, both in the hip and shoulder. The patients died, and matter was found in the several joints above named.

Perhaps the most remarkable phenomenon connected with rheumatism is the rapidity with which it shifts its seat from joint to joint. This has been attributed to metastasis, and held by some to be an argument against bleeding; but I doubt whether either the inference or the ground assigned for it be free from objection. The extension of rheumatism appears to me more striking than its metastasis. When a joint is considerably swollen, it is not usual to see that swelling disappear very suddenly; but rather this: after a time the pain in the situation first attacked becomes moderated, and the disease extends to other parts successively; the swelling speedily diminishing, but usually taking two or three days after the patient has ceased to complain of pain to subside entirely. As to the metastasis to the heart, of which we hear so much, it seems to me to be quite imaginary: that is to say, imaginary as to there being any metastasis. It is infinitely rare to see a case in which rheumatism suddenly leaves the joints while the pericardium becomes simultaneously affected, but it is of every-day occurrence to see the heart passing through the disease *pari passu* with the limbs. Nay, in some instances the heart is the part first attacked. I have more than once known patients seized with symptoms of pericarditis at a time when they had no *other* rheumatic affection, and in whom, next day, one or more joints became affected with pain, swelling, and redness, the disease of the external and internal fibrous membranes thenceforward running their course together.

But it may be said that the rheumatic affection of the heart differs from ordinary inflammation; and I have met with some who have affected to distinguish between rheumatic and common pericarditis. On this point I shall only remark, that I regard the assumed power of diagnosis (independently of the presence or absence of rheumatism externally) as a piece of refinement, if not affectation.

My object in the preceding remarks has been to shew that rheumatism does not differ so much from other inflammations as, in my humble opinion, to warrant the great difference in the treatment adopted; but I would be understood as speaking at present of the acute stage alone; because if this has been suffered to pass, various changes in the pathological condition supervene, requiring other, and often very dissimilar, modes of treatment. As I have said, many assume, as an established principle, that acute rheumatism cannot be cut short by bleeding; but I know that of those who give a tolerably confident opinion on this subject, very few have ever tried the method they condemn. Last winter two severe cases of rheumatism were brought into St. George's Hospital: one presented great tumefaction and redness of the left hand and wrist of only thirty-six hours' duration: the other had more general pain of the limbs, but no swelling nor redness, and had several times suffered from rheumatism. Dr. Alexander, a very intelligent young physician, then attending the hospital, told me that he had seen acute rheumatism very rapidly cured by bleeding, without any thing else, and at his suggestion both patients were bled largely. In the former case the disease was literally *extinguished*, for the patient was well next day—quite free from pain, and had no recurrence of the symptoms: in the latter the pain was moderated, but only yielded ultimately to other remedies. Now it is in that stage of rheumatism only of which the former may be regarded as a type, that I have since, and more particularly very recently, adopted the plan of bleeding and purging in the same manner, and to the same extent, as in other acute inflammations. Hitherto I have

had no reason to distrust the expediency of this plan; and I subjoin, in illustration, some cases thus treated, not picked for the purpose, but being all the patients admitted with acute rheumatism at my last "taking in," except one case of pericarditis with old disease of the heart;—(case of Collard, described above.)

To one other point connected with this subject I beg to direct attention. I have read and heard that the risk of pericarditis in rheumatism is increased by bleeding. On what does this opinion rest? When pericarditis does occur, we bleed, and experience justifies the practice. Are we, then, to believe that the very means which, after pericarditis has occurred, tends to subdue it, if adopted when it is absent, paves the way to its approach? I apprehend that a simpler and truer explanation of the fact (if it be a fact), that pericarditis occurs more frequently when patients have been bled than when they have not, is to be found in this—that few practitioners have recourse to bleeding except in the more acute and severe cases. Now it is just in these that pericarditis is of most frequent occurrence, whatever treatment may have been employed. In one of the subjoined cases (that of Sarah Gurney) it will be seen that the patient, having as yet no pain in the chest, was bled, soon after which pain in the region of the heart came on, which still continued at the time of her admission next day, when, being bled a second time, the cardiac symptoms entirely disappeared. Now surely the fair inference from this, is not that the first bleeding caused the heart affection, but that it was not sufficient to prevent the extension of the disease to the pericardium, then already supervening.

But I by no means wish in any case to limit the treatment of the most acute rheumatism to bleeding (except to ascertain its actual degree of efficiency.) I only wish that if it be entitled to the same rank here as in other acute inflammations, it should enjoy that rank. The more rapidly the inflammation of any important part produces effusion, the more speedily must measures be adopted to counteract this tendency. Thus in croup we bleed to reduce the inflammation, and probably if we were confined to one remedy this would be the safest to choose; but as we are not so limited, and as the effusion of lymph into the trachea might suffocate the patient, even although the inflammation which produced it had ceased, so, while we bleed, we also give calomel with a liberal hand. Now in rheumatic pericarditis, even if we were certain that blood-letting alone would arrest the inflammation, we should still in common prudence give mercury, as the best antidote to the effusion; and thus in the case of Collard above mentioned, it was begun in doses of five grains every four hours, combined with opium, and afterwards continued in doses of five grains every six hours.

Having thus endeavoured to guard myself, I trust I shall not be misunderstood as to the manner or extent to which I would suggest that a trial be given to blood-letting and purging on the onset of acute rheumatism; and I beg to refer to the recent work of M. Bouillaud for a more elaborate and skilful exposition of the same doctrines—doctrines which in France have much more novelty than here, where, after all, the question of bleeding is only one of degree.

CASES OF ACUTE RHEUMATISM.

Case I.—*General Bleeding twice, and Leeching once, in 24 hours; Purging with Senna and Salts; Cure.*

James Crow, ætat. 19, footman.

Dec. 17.—Was seized a week ago, after exposure to cold, with acute pain in the feet and ankles, which parts soon became considerably swollen and red. He had fever, and was confined to bed. Two days ago the pain in the lower limbs began to abate, the wrists becoming simultaneously affected in a similar manner. This continued to increase; and on his admission, which took place yesterday afternoon, the left hand and wrist were considerably swollen, and very painful. The pulse 88, bounding.

He was bled to ℥xii. and ordered a senna draught, which was taken this morning.

Says the pain is better to-day, but not gone. The swelling is also diminished. Pulse 74, very large, and with a peculiar harshness. No pain or uneasiness referred to the region of the heart; but the ear detects a loud bellows sound alternating with the pulsations at the wrist.

It appears that about four years ago he suffered from violent palpitations, and has ever since been subject to a recurrence of

the symptoms on any slight exertion. Has never had rheumatism before.

The blood drawn yesterday exhibits a large and very firm coagulum, but without buff or cupping. Tongue thickly furred; bowels freely purged.

Mittatur Sanguis ad ℥xiv. Applicentur Hirudines xii. sterno. Rep. Haust. Sennæ cras mane.

18th.—Entirely free from pain; swelling of wrist, &c. considerably diminished. Blood exhibits the same characters as before. Bowels again freely purged; pulse 72, soft and natural; bellows sound of heart much less remarkable.

On the 19th he had no pain, and the swelling was nearly gone. On the 22d, having continued entirely free from complaint, he was discharged, with directions to apply to me (as he lived in my neighbourhood) if he had any recurrence of his complaint. I have not since heard of him.

Case II.—*General Bleeding thrice, and Leeching once, in five days: Purging with Senna and Salts; Cure.*

James Sharp, ætat. 21, labourer.

Dec. 23, 1835.—Has suffered for ten days from pain in the knees, attended with swelling. Two days ago the hands and wrists were also attacked: they are now swollen, with slight redness, and total inability to move the parts. He has also acute pain in the right shoulder, which, however, does not appear to be swelled. Pulse 84, unequal, and with occasional intermission; no uneasiness referred to the heart, and no anormal sound to be heard on applying the stethoscope over it; skin pungently hot; tongue furred.

Mittatur Sanguis ad ℥xx. Hab. Haust. Sennæ cras mane.

24th.—Pain much diminished in knees and shoulders, but not in the wrists; pulse and skin as yesterday; bowels purged; tongue still loaded; blood drawn yesterday exhibits a large firm slightly buffed coagulum.

Rep. Venesectio ad ℥xx. quamprimum. Haust. Sennæ cras mane.

25th.—Says that he "has very little pain any where;" moves his hands freely, having no pain in them, and much less swelling; pulse 72, soft; blood much cupped and buffed; bowels have acted only once, and that but slightly.

Rep. Haust. Sennæ quamprimum et cras mane.

26th.—The only remaining pain is in the right knee, which is still rather "sore." Bowels have been freely purged; tongue cleaning.

Applicentur Hirudines xiv. genu sinistro. Haust. Sennæ alterno quoque mane.

28th.—Knee was greatly relieved by the leeches; but was attacked with pain in the right hand and wrist yesterday afternoon, the part being now swollen, and with perceptible redness. [This relapse followed within a few hours after the weather became damp, on the breaking up of the frost.]

Mittatur Sanguis ad ℥xii. Rep. Haust. Sennæ cras mane.

29th.—Is again entirely free from pain, and complains only of weakness.

[This patient was kept in the house in consequence of one of the leech-bites festering. He continued free from complaint till the 18th January, when, being told that he must leave the house, he next day said that he had a recurrence of pain in the right shoulder: this pain (which I presume never existed) left him as soon as the immediate risk of being discharged had passed.]

Case III.—*Bleeding twice, Leeching once, in five days: Purging with Senna and Salts; Cure.*

John Pater, ætat. 25, coachman.

Dec. 23d.—Admitted yesterday, when he complained of acute pain in the feet, ankles, and knees, with swelling, and a slight blush of redness. Pulse 96; skin hot; tongue furred. Was ordered yesterday—

V. S. ad ℥xiv. Haust Sennæ cras mane.

Blood cupped and buffy; bowels purged; symptoms much relieved.

Pulv. Ipecac. Comp. gr. x. h. s. Haust. Sennæ cras mane.

25th.—So much better as to have got up and walked about the ward this morning (without leave).

Rep. Medicamenta.

26th.—Rather more pain last night. Pulse 94, with some sharpness.

V. S. ad ℥xii. Rep. Alia.

28th.—No pain since he was last bled, except a little in the right knee at night; pulse 80, soft; bowels moderately opened each day.

Hirudines xii. genu dextro. Rep. alia.

From this time he rapidly recovered, without any farther relapse.

Case IV.—*General Bleeding and Leeching: Purging with Calomel and Black Draught; immediate Relief; Relapse on fourth day: Repetition of Bleeding and Purging; Cure.*

Sarah Gurney, ætat. 18, house-maid.

Dec. 21th.—Attacked four days ago,

after exposure to cold, with acute pain in the feet, ankles, hands, and wrists, all of which are swollen, and the latter of which are red. Has pain also, though not to so great a degree, in the back and larger joints; countenance is expressive of much suffering; and she either lies perfectly motionless, or cries with pain when moved. Has pain in the region of the heart, which, she says, came on the day before yesterday, she having been bled in the morning. On applying the stethoscope, a slight bellows sound is perceptible;—somedegree of rubbing sound (?) Pulse 100, bounding; skin hot and dry; tongue dry and furred; bowels purged by medicine taken before her admission.

Mittatur Sanguis ad ℥xiv. Applicentur Hirudines xx. regioni cordis.
Calomel gr. iij. hora somni. Haust. Sennæ cras mane.

25th.—Appearance greatly improved; no pain whatever in the chest, and that of limbs nearly gone; swelling much diminished; chief remaining pain is across the back, between the shoulders; bowels have only acted once; pulse 90, softer; skin cooler; tongue cleaner.

Hab Haust. Sennæ quamprimum et cras mane.

26th.—No pain, except in a slight degree when she moves; swelling of ankles and wrists has almost entirely disappeared; pulse 90, soft; no anormal sound perceptible on examining the chest; sleeps badly.

Pulv. Ipecac. Comp. gr. x. hora somni.
Haust. Sennæ al. mane.

28th.—Suffered a relapse yesterday afternoon (in common with several other rheumatic patients), in consequence of a sudden change in the atmosphere. The left hand and wrist are again swollen, and very painful, with perceptible redness; pulse 104, sharp; tongue pretty clean, but dry; bowels freely purged.

Mittatur Sanguis ad ℥xii. Calomel gr. iij. h. s. Haust. Sennæ cras mane.

She was next day entirely free from pain, and suffered no farther return of the symptoms, having been detained in the hospital till January 13, to guard against the risk of relapse.

Hydriodate of Potass in certain forms of Chronic Rheumatism.

It will be seen by the preceding table that several of the cases admitted as rheumatism were of a chronic character, and attended with thickening of the periosteum, or induration about the joints, particularly the ankles, wrists, and fingers. As a general rule such cases are benefited by sarsaparilla, and some of the above were unquestionably of syphilitic origin. In more than one, however, the effect of the sarsaparilla seemed to carry the patient on to a certain point in his cure, after which its effects ceased. Under such circumstances the hydriodate of potass, in doses of gr. iii., gradually increased to gr. xv., three times a day, speedily renewed the curative process, and completed the recovery. These were cases in which mercury had been freely used at an earlier period. In several other cases of thickening about the periosteum and ligaments, not apparently connected with syphilis, the hydriodate of potass was attended with speedy and decided benefit. One of those was a very obstinate case of inflammation of the synovial membranes of the ankle-joint and middle finger, connected with gonorrhœa: the disease was rapidly cured by this remedy, after a great variety of others had been tried in vain. A case of chronic enlargement of both wrists and both ankles, of nine months' standing, and of rheumatic origin, is now under treatment, and is rapidly yielding to the sarsaparilla with hydriodate of potass.

Note on the rate of Mortality in St. George's Hospital.

In the British Medical Almanack for 1836, a table is given, which professes to illustrate the comparative rates of mortality in the different hospitals of the metropolis. By the table in question it would appear, that at St. Bartholomew's the rate is only 7·6 per cent., while, at St. George's, it is 10·6. But, in estimating the value of such statements, it is essentially necessary to be made aware of the data on which they are founded, and of how far the results given are deduced from corresponding premises. In all hospitals at which wards are set apart for particular diseases, not generally of a fatal nature (such as venereal or ophthalmic cases, or certain chronic maladies—as uterine affections, &c.), the rate of mortality must necessarily be lower than at those institutions where this is not done. Again: the rate of mortality will almost unavoidably be higher at those hospitals where the number of applicants much exceeds that which can be admitted. Now both these causes are in operation at St. George's; it has not wards for

cases of the nature first alluded to, while, as to the latter circumstance, the number of applications greatly exceeding the means of accommodation, a selection is systematically made of the worst cases. Another very important point to be inquired into is, whether persons brought into hospitals with fatal accidents are or are not returned among the deaths. At St. George's such cases are included in the list of those who have been treated in the hospital, although, in many instances, the patient is dying when admitted.

During the year 1835, the admissions amounted to 2175; the deaths to 215, or very nearly 10 per cent., but of these, not fewer than 51 were "deaths from accidents;" and deducting this number both from the admissions and the total mortality, we have the deaths reduced to about 1 in 13, or something less than 8 per cent.; which brings it within a fraction of the lowest rate. According to the British Medical Almanack, the average mortality of the Paris hospitals amounts to 12 per cent., and that of La Charite, of Berlin, to 15·1 per cent.; but this is so much greater than the mortality of the London hospitals, that I cannot help suspecting that we have not yet sufficient data on which to form a correct estimate of the comparative rates of mortality in different hospitals, either at home or abroad.

CASE OF FATAL HÆMORRHAGE FROM LANCING THE GUMS.

To the Editor of the Medical Gazette.

SIR,

IN Mr. Pereira's lecture on the history and use of Leeches, in the Gazette of the 9th of this month, he mentions the death of a child from the bite of a leech, and adds, "In some persons there appears to be an hereditary predisposition to hæmorrhage, so that very slight wounds are attended with serious and even fatal effects."

These observations so forcibly recal to my recollection a case which occurred in my practice at Bromley, a few years ago, that I trust you will not consider it unworthy of a place in your valuable journal. It was that of a child, who died from having the gum lanced.

On a Sunday morning I was called to visit the child of Mr. R. Stockwin, about six months old, who had been suffering for some days from diarrhœa. Observing the upper gum much swollen, I advised the mother to allow me to lance it, telling her that teething was probably the chief cause of the child's illness. To this she very reluctantly consented. About eight o'clock in the evening a messenger was sent to inform me that the child's gum had continued to bleed the whole day. As I supposed it could not be of serious consequence, and as the parents of the child lived two miles off, I sent a styptic lotion, and promised to call in the morning.

I was sent for early on the following morning, and found the child pale and exhausted from the loss of blood. It was constantly crying and sucking; and the mother's neck, as well as her clothes and those of the child, were covered with blood. I never, in the course of a very long practice, witnessed so deplorable and distressing a sight; and it was very difficult to know what to do. I tried styptics in various forms, such as a very strong solution of sulphate of copper, one of alum, spirit of turpentine, and nitrate of silver, but all to no purpose, as no application could be retained on the wound for an instant, owing to the child's constant attempts to suck. I then had recourse to the actual cautery, by means of a heated skewer; but it did not in any degree stop the bleeding, and the child died on Tuesday.

Now suppose such a case had occurred in a family of high rank, and the child had died, what a sensation would it not have caused, and how highly injurious might it not have proved to the surgeon's reputation! A similar case may happen again. Surely, then, it is important to know what mode of treatment would be likely to arrest the hæmorrhage; and I hope that some of your able correspondents will favour us with their opinion on the subject.

I ought, in conclusion, to remark, that there certainly existed in this child a predisposition to hæmorrhage, as the father told me, after its death, that if only accidentally scratched by a pin, the part would bleed for several hours.

I remain, sir,
Your obedient servant,
R. T. TWYNTON,
Surgeon.

39, Queen-Square, Bloomsbury,
Jan. 22, 1836.

FATAL CONSTIPATION CAUSED BY A KNOT OF TENIÆ.

To the Editor of the Medical Gazette.

SIR,

SHOULD you deem the inclosed brief case of constipation (on account of its cause) at all interesting to your readers, you will oblige a constant reader by inserting it.—I am, sir,

Your obedient servant,
J. K. PARKINSON, M.R.C.S.

Milverton, Jan. 20, 1836.

The parents of a poor boy, æt. 4 years, requested my attendance, on Wednesday last, in consequence of his (to use a provincialism) not having had "the use his body" for three days. From that day no means were left unemployed which were considered at all available, but with no effect; and on the Monday following, after the most acute suffering, he died. His symptoms at last presented all the features of strangulated hernia, except the local one. A few minutes before his death, his mother found he had passed something in the bed, which proved on inspection to be five teniæ, inseparably knotted together into a round hard ball. I must mention that an enema was not employed, owing to the parents persisting against it, as some ignorant neighbours (women) gave it as their opinion that it would be too strong.

MEDICAL GAZETTE.

Saturday, January 23, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

CROWN AND ANCHOR MEETING.

THE event of the week has been the meeting of medical students at the Crown and Anchor. Nearly a thousand, it is said, were congregated on the occasion—some, we believe, from a well-intentioned, however misguided, motive—others for frolic sake—and by far the greatest number out of pure curiosity. Mr. Wakley, M.P., promised to lionize: "he pledged himself," said the advertisement, "to be present." No doubt; pledging is a part of the system of the *pledged* member for Finsbury. The chair, too, it was announced, was to be taken by a Mr. Meade, a private teacher — or "grinder," as it is commonly termed—and a protegé of the *honourable* Finsburian.

Of a meeting called together under such auspices, much good could scarcely be anticipated. No professional man of any rank—no teacher who might have a moral weight with the students—could venture to be present. But Mr. Carpue and Mr. Liston were there.

The accounts which we have read in the newspapers of the general conduct of the meeting, have not been very consistent—some describing it as very decorous, and some just the reverse. We have taken pains to gather correct information on the subject, as well as concerning the previous and subsequent proceedings, and we believe that the *facts* which we are enabled to state cannot readily be assailed or denied.

It appears, then, that on Thursday evening fortnight a candidate for the license of the Apothecaries' Society was rejected, his examiners having found him insufficiently prepared. Whether he was really so or not, we cannot pretend to say, having at present no data on which to rest an opinion. The candidate himself was highly indignant, and in the heat of passion wrote shortly after a letter to the Court of Examiners, demanding a *public* examination, giving, at the same time, a copy of the said letter to the Editor of the Lancet for publication. On the subsequent Thursday evening Mr. Meade was in attendance; and the alarm being sounded, calling together, at a short notice, a large assemblage of students, this gentleman took up his

position at a public-house in the neighbourhood of the Hall, where he harangued his excited auditors from one of the windows. But this nuisance presently attained such a height, that the City Marshal had to interfere and cut short the gentleman's eloquence. On the breaking up of this tumultuous assembly, some of the windows of Apothecaries' Hall were smashed.

All was now organized for a grand display at the Crown and Anchor. Meade and Wakley were in their glory. The first denounced the *system* pursued at the Hall, of rejecting pupils of his: he amused his auditors with *his* account of the questions and answers on which gentlemen were rejected; and ended by declaiming on the necessity of reform in these and many other things. Wakley poured forth his usual virulence against all the medical corporations, particularly, of course, against "Rhubarb Hall." He prophesied, as usual, the downfal of "corruption," and the speedy uprise of "One Faculty" in its stead. He promised *his* aid (!) in Parliament to forward the cause of the students, and offered most magnanimously to present their petition.

Mr. Wakley, *M.P.*, is obliged, we all know, to labour in his vocation. If he does not keep the cauldron in a "bubble, bubble, toil and trouble" condition, his occupation is gone: hot water is his element; and if he does not attend meetings (no matter of what kind), and get into the newspapers, the worthy electors of Finsbury will discharge him. Besides, it is his interest to hoax the students,—through a pure and disinterested regard for them. And, moreover, what could he do in the present case? He met the parties, without any contrivance of his own, was pressed, and in consequence pledged himself, to attend.

Will this sort of excuse serve the turn of Mr. Liston? This gentleman, we understand, actually gave his pupils a holiday on the occasion, and hurried off hot-foot with them to the place of meeting. How amiably kind, and how considerate of the interests of his class! No doubt the opportunity was irresistible. It is a fine thing to be a popular man; and it is only what we are in duty bound to do—to support our friend Wakley. There, then, met face to face the worthy pair, in congenial coalition. Of the speech of the "celebrated surgeon," as one of the newspapers called him, we have been able to learn nothing farther than that he spoke, or perhaps attempted to speak.

As to poor Mr. Carpue, we cannot conceive what brought *him* there; unless to while away some of his idle moments with recollections of days gone by. Friend Wakley, besides, wanted *respectable* support.

Now what *are* we to think of a meeting, however quietly it may have been conducted, which was assembled under such patronage? We tell the students that they have been grossly imposed upon. They might have met together in large numbers, and have carried much weight in their proceedings (always supposing that they had a legitimate object for their assembling), had they carefully eschewed the agitators who took them under their wily protection. Such "friends," they will see, when a little older, or a little calmer, are worse than avowed enemies: at present they can scarcely appreciate the motives of those worthies.

When we say, *if* the object of their assembling were legitimate, we wish to guard ourselves from being understood to pronounce any opinion on the merits of the present case. We believe that (apart from the agitating purposes of the volunteer chairman and "friends") the avowed object of the students was the redress of grievances, real or supposed, connected with their examinations at the Hall. If those grievances truly ex-

ist, we must, of course, admit that the conduct of the students in calling a meeting, in order to secure better treatment in future, is both proper and laudable.

Now, from all we can hear, the charges made against the Court of Examiners, more particularly with reference to the recent case of rejection, are principally two; both of them of a sufficiently serious nature. The first is, that the *matter* of the examination was, as it is said frequently to be, captious, quibbling, and capricious, and that good answering was refused. Secondly, that the *manner* of the examination was uncivil in the extreme—rude, and such as to irritate and disconcert the candidate.

With regard to the first of these accusations—in support of which we have at present no more than the vague assertions of certain rejected men and their grinders—we would propose that it be put to the proof. We say, *let the late examination be published; let the Court of Examiners be called upon to lay before the public the questions and answers in the case under discussion;* and if they refuse, let judgment go by default—the world will know what to think of their refusal. But this cannot well be done without the consent of the rejected candidate: let him, therefore, instead of calling for a *public* examination (contrary to all precedent, and which would lead to obvious inconveniences and difficulties hereafter), *let him demand the publication of the examination of which he complains;* and if the Court of Examiners refuse to concede that very fair request, they will stand condemned by their own act, and we shall be among the first to pronounce sentence upon them.

The other charge is one, for which, perhaps, so simple a mode of defence cannot easily be suggested. There are so many ways of shewing incivility, so many modes of taking it, and it is altogether so relative a thing, that it cannot readily be adjusted by any invariable standard. But there is a degree of rudeness too strongly marked to be misunderstood; and such, we apprehend, is the case in the present instance. We have reason to believe, upon what we consider to be unquestionably good authority, that the conduct and bearing of some of the members of the Court, to those who come before them, are not only wholly deficient in the amenities which conciliate, but repulsive and unwarrantably coarse. There are certain members, in short, who are particularly noted for this sort of behaviour to candidates; and we have no hesitation in saying, that if they cannot conduct themselves otherwise, their presence ought as speedily as possible to be dispensed with. It *may* be that the examinations are sufficiently good; but who can expect fair play where such petty tyranny, and paltry displays of boorish bad manners, are exercised? Besides, the example is catching: when the leading members of the Court pour out the venom of their spleen on those with whom they come in contact, it can scarcely be expected that the Officers of the Court should be more orderly or better-behaved than their superiors. We regret to learn that gentlemen are in numerous instances subjected to incivilities from the very moment, or even before, they cross the threshold of the establishment at Blackfriars.

The redress of these sources of annoyance, is, we repeat, a very proper object for the intervention of parties really aggrieved by them. But such persons should take care to ascertain that the first grievance—that relating to the alleged captiousness of the examinations—has some other foundation than the interested statements of grinders and restless agitators. Any hook will serve a selfish, mortified, and unemployed legis-

lator, to introduce himself into the councils of those who must eventually be injured by his interference. Nor are the students to fancy that their cause can in any way be bettered by the co-operation of a couple of disappointed surgeons, long noted for their turbulence and the pertinacity with which they thrust in their "noses" where they are not wanted. Let such gentry be eschewed altogether: and with moderation and gentlemanly demeanour in the conducting of such measures as they may think it prudent to adopt, the medical students of London may exhibit an example to those of the provinces and other parts of the empire, at once creditable to themselves and the nation to which they belong.

Since the preceding was written, we have seen a public protest, on the part of the King's College students, "disclaiming all participation in the intemperate proceedings of the Crown and Anchor Meeting." This at least shews that the business of Monday night was not the act of the *general* body of the London students. We have heard, moreover, that other schools also intend to enter a similar disclaimer.

RESUSCITATION OF THE APPARENTLY DROWNED, OR DEAD.

We perceive, from the last report of the Royal Humane Society (1835), that it is in contemplation still further to simplify those admirable precepts, which have been so extensively circulated, for the recovery of persons in a state of suspended animation. Experience seems to show that the practice of attempting to inflate the lungs had better be dispensed with; at least by non-professional people. What Mr. Dalrymple says on the subject, in a note addressed to his brethren of the Committee, is particularly worthy of being quoted:—

"It has been the peculiar object of the Committee that the instructions should not only be simple and of easy application, but, above all, that they should be safe and harmless in the hands of non-medical persons; because artificial respiration is exceedingly difficult of performance by persons ignorant of the structures concerned, or unaccustomed to the operation; and even if they succeed in introducing air into the lungs, there is still much danger attendant upon the mode by which it is impelled, and the force and degree of violence used. This the annual reports of the Society within the last few years, and since the publication of M. Leroy's excellent memoir, have, to a certain extent, insisted on. It is also a singular fact, that one of our most active and useful medical assistants, Mr. Woolley, residing near the Serpentine, *in all the cases in which he has been successful in restoring suspended animation, has never performed the operation of inflating the lungs;* and in all those cases wherein he did use the bellows, his exertions were of no avail. I do not mention this to throw discredit upon the process of artificial respiration, since I firmly believe that there are cases in which it has been, and will still be, of the highest service; but rather to show that those cases are comparatively rare, and that with the difficulty of its application by non-medical men, the dangers attendant on its use are not only augmented, but much valuable time is lost which might be better employed."

The same gentleman also notices the danger of foreign matters passing into the air-passages, in the act of introducing brandy and water into the stomach, ere the contents of that organ have been satisfactorily removed. He suggests, in consequence, that with regard to these several points, some modification might be adopted in the instructions, suited to the improved state of medical knowledge.

We are glad to observe another excellent remark of Mr. Dalrymple's, relative to the detailed methods of treatment given in the Society's yearly reports. This detail, he suspects, is frequently the sole guide of medical men, especially junior practitioners, in their treatment of asphyxia. "It is therefore," he says, "of the highest importance to the Royal Humane Society, that its published methods of treatment should be at once the best and the most scientific text-book upon the nature and treatment of asphyxia, from

whatever cause originating, whether with reference to the additions which are constantly making to our present stock of knowledge on that difficult and interesting branch of the medical art, or as it regards the best and most approved apparatus to be used for the purpose of restoring life.

"The question is, therefore, whether it might not be advisable for the Committee to solicit the co-operation of several of the medical friends of the institution, in reviewing what has been already done by others, verifying or not their conclusions; and instituting a series of experiments, with a view to the full development of the theory and treatment of asphyxia."

It is the intention of the Committee, it appears, to follow up Mr. Dalrymple's observations; and they hope to have it in their power to give, in their next annual report, the results arrived at by the medical referees. We need scarcely add that we shall be anxious to hear more on this important subject.

LECTURES ON SUBJECTS CONNECTED WITH CLINICAL MEDICINE;

Delivered at St. Bartholomew's Hospital,

BY DR. LATHAM.

ON SYMPTOMS.

Possible Fallacies of Auscultation—How it may lead to an erroneous Diagnosis; in Pneumonia; in Dilatations of the Bronchi; in Emphysema—Pathology of Dilatations of the Bronchi—Pathology of Emphysema—How the intimations of Auscultation and Percussion may apparently contradict, yet really confirm, each other.

I HAVE endeavoured to speak of the Auscultatory Signs that belong to the Lungs as plainly as I could. First I took them singly, and tried to fix their separate value by a reference to the simpler forms of disease; and then I took them together, seeking their relative and combined value in forms of disease that are more complex. And thus I found that a single Pathological Condition might be denoted by a single Auscultatory Sign; that in Bronchitis, when it had not passed the stage of mere vascularity, there was nothing but a *dry* Sibilus, and when it had reached the stage of effusion, nothing but a *moist* Crepitation. Moreover, I found that, as diseases were cumulative, so might their Auscultatory Signs be cumulative also; and that a mixed case of Pulmonary Consumption often contained every one of the Auscultatory Signs that have been mentioned.

These Signs, both singly and cumulatively, I have followed as far, perhaps, as they can be altogether trusted in the diagnosis of pulmonary diseases. Not that, beyond this point, they have no further aid to contribute, only they need more confirmation from concurrent circumstances, and require more care on our part, to avoid certain errors, to which, if too implicitly relied upon, they are apt to conduct.

Auscultation is not infallible. I have known it betray the most wary and experienced into downright error; as when a certain sound, which in forty-nine cases indicates one thing, has in the fiftieth case indicated another. You ought to be aware how this may happen. As also, when the several Auscultatory Signs of one and the same case seem to set themselves in opposition to each other, one indicating this thing, and another that; one confuting what another affirms. This apparent contradiction is at first very perplexing; but, being understood, turns out to be no contradiction at all; and the real consistency and the apparent contradiction furnish together a sure diagnosis of a particular form of pulmonary disease. You ought to be aware how this, too, may happen.

In what manner, then, an Auscultatory Sign may give false intimations, and how several signs may seem to contradict, and yet be perfectly consistent with each other, I will now endeavour to explain. For this purpose I must touch a little upon some points of Pathology.

It has been by the light of certain facts in Pathology, considered as general truths, that Auscultation has reached some of its most important conclusions.

Of such facts these two deserve to be especially noticed; viz. that Tubercles and Tubercular Cavities have their origin in the upper lobes, and Inflammation its local origin in the lower lobes, of the lungs.

These two facts are so generally true, that they have been set up as signals (if I may so say) to steer our diagnosis by; and Auscultation has reached some of its safest conclusions entirely from faith in them.

But ordinary diseases will sometimes occur under extraordinary circumstances, or in unusual situations; and then we are as apt to be thrown out in our diagnosis as the pilot is in his course upon any unexpected alteration of lights or signals

on the coast. He makes false points, and so do we.

Thus in every instance of exception to the two general truths which have been specified, there is a perilous chance that Auscultation will lead us wrong.

In forty-nine cases out of fifty Pectoriloquy is a direct symptom of a cavity formed in the lungs, the result of Tubercular Disease, or the result of Inflammation. Then comes the fiftieth case, in which there is Pectoriloquy, arising not from a cavity either tubercular or inflammatory, but from some other condition; and in this fiftieth case the Pectoriloquy, I suspect, almost always deceives us.

A young woman (Mary Taylor) was admitted into the hospital in September, 1833. For two or three years she had been liable to slight coughs, and in the last spring had suffered Influenza. The Influenza passed away, but a slight cough was still left behind.

Three days before her admission she had a rigor, inability to lie on the right side, and pain shooting from beneath the right clavicle through the chest to the scapula.

At her admission she was flushed and hot, her respiration hurried, her pulse 112 in a minute, and full and soft; and she complained of pain in the situation just mentioned.

Auscultation found a healthy Respiratory Murmur, unmixed with any unnatural sound, throughout the entire left lung, but in the right lung Cavernous Breathing, and a loud Pectoriloquy above the spine of the scapula, and small Crepitation all around it; also a space beneath the clavicle dull to the ear, and dull to Percussion, while the rest of the lung was healthy. Six leeches were the most active remedy which her strength would admit, and they were applied beneath the clavicle.

She was delirious through the night, and perspired greatly. The next day she was more flushed: her dyspnœa was aggravated; her pulse had gained in frequency, and had lost in power; she was altogether very much sunk. The Pectoriloquy was still clear and evident, and the *small* Crepitation still every where about the scapula, and moreover in front, about the mamma.

Our diagnosis in this case was, that one considerable vomica at least existed in the apex of the right lung, and that *acute* Inflammation of the vesicular structure had arisen all around it.

She was treated by remedies as active as her feeble circulation would admit, chiefly by leeches to the surface opposite the parts where the Crepitation was heard. In four days the Crepitation began to abate, and in six it was gone; and, as it gradually went away, the Respiratory Murmur gradually returned, until it entirely took its place.

But what became of the Cavernous Respiration and Pectoriloquy? These surely remained unaltered; for the vomica could not be so soon cured, although the surrounding inflammation might?

Not so. But the Cavernous Breathing and Pectoriloquy were first changed into Bronchial Respiration and Bronchophony; and these last soon ceased; when nothing was any where heard but the healthy respiratory murmur. The patient was well, and the whole work of reparation was accomplished in a week.

The diagnosis, I have said, was that she had one large vomica at least at the apex of the right lung, and that acute inflammation had arisen around it. I apprehended that she would die quickly, so fearfully rapid was her sinking in the two first days after she reached the hospital. But a week from that time she was well, and a fortnight from that time she was discharged from the hospital.

In this case I was entirely deceived in regard to one supposed ingredient of the disease, the Cavity. And I was entirely deceived *by Auscultation*. Cavity there was none, which is the very thing we expect to find at the apex of the lung. But Inflammation there was, and of the acutest kind, and nothing but Inflammation, which is the very thing we *do not* expect to find there.

It is quite certain that the Cavernous Breathing and Pectoriloquy were formed in a bronchial tube passing through a portion of lung which had become consolidated by inflammation. As the lung began to be more permeable, the Cavernous Breathing and Pectoriloquy lost their distinctness, and were changed into Bronchial Respiration and Bronchophony; and when the lung became entirely free, the healthy murmur was re-established alone and unmixed with any unnatural sound whatever.

Let it, however, in justice be remarked, that although Auscultation misled me both in my diagnosis and prognosis, yet it betrayed me into no error of treatment. Nay, but for Auscultation, I might have treated the case less precisely and effectively. It pointed out to me the very part where the disease was, and told me that Inflammation was at least an ingredient of it; things which could only have been conjectured without the aid of Auscultation.

There are certain conditions of the Lungs now familiarly understood (or at least familiarly spoken of, as if they were understood) by medical men, which had been little investigated, and were little known,

before Auscultation directed attention to them; and yet, both pathologically and practically, they are of the highest import. Laennec seems to have been first led to make accurate inquiry into the nature of Bronchial Dilatations, and Dilatations of the Vesicular Structure of the Lungs, for the sake of verifying certain Auscultatory signs. And all who concern themselves with Auscultation, and seek in like manner to verify its signs by dissection, will soon feel their obligation to him for his elucidation of these subjects.

Bronchial Dilatation may take place in one or in several branches, or in almost every branch, throughout the lung; it is, however, most frequently met with in the upper lobe, and nearer its anterior surface.

A Bronchus may dilate, and still preserve its natural cylindrical form. That, which would not naturally receive more than a knitting-needle, becomes large enough to admit a crow-quill, or a goose-quill, or even a little finger. It seldom happens that the common bronchial trunk is sensibly dilated, while the branches become larger than the trunk from which they are given off.

But a Bronchus may dilate and not preserve its natural form. It may dilate so as to take the form of a cavity, having the same size and shape as a vomica; it is distinguished, however, from a vomica, by the structure of the Bronchus being traceable into it; its mucous membrane, its fibrous membrane, and sometimes vestiges of its cartilaginous rings.

Again, a Bronchus may so dilate as to form several cavities; that is, it may dilate and then contract itself again to its ordinary calibre, and dilate and contract again and again at several spaces in its course. Thus, upon dissection, the lungs have sometimes appeared to be beset with vomicæ or abscesses full of matter, which, upon examination, have turned out to be so many cavities formed from the dilatation of several bronchial ramifications.

When the Bronchi are numerously and extensively dilated, they so compress the intermediate pulmonary structure as to preclude the admission of air into its vesicles; and thus it becomes squeezed together and flaccid, exactly resembling lung which has suffered from pleuritic effusions.

There seems good reason to believe that the Bronchi become dilated by the long-continued residence and accumulation of morbid secretion within them; and that the bronchial trunks are less frequently dilated than their branches, because this morbid secretion is accustomed to linger within them for a shorter time, being more easily dislodged by forced expiration, *i. e.* by Cough.

I know no instance of dilatation of the Bronchi where it has not followed or accompanied some disease specially characterized by abundant Bronchial Secretion; such as protracted Hooping-cough, Chronic Bronchitis, or Catarrh.

Surely this little pathological sketch will at once shew what the Auscultatory sounds must necessarily be which accompany dilated Bronchi. If they be enlarged uniformly through their whole course, they must give rise to Bronchial Respiration and Bronchophony, and much more so, if they pass through compressed and impervious lung. If they be formed into cavities, they must occasion Cavernous Breathing and Pectoriloquy; and when those cavities contain fluid (as they generally do) they must produce Gurgling Respiration and Gurgling Cough.

But Bronchial Respiration and Bronchophony, Cavernous Respiration and Pectoriloquy, Gurgling Respiration and Gurgling Cough, have been dwelt upon and explained as the almost certain signs of condensed lung and pulmonary abscesses; of lung, condensed by the products of common Inflammation or of specific disease; of abscesses formed by Inflammation, or left after the evacuation of tubercular matter. And of such conditions they must still continue to be the *almost certain* signs. It is only when they are interpreted by the special circumstances of some particular case, that they can be construed into a different meaning, or serve to indicate Dilatation of the Bronchi.

But the circumstances are *seldom special enough* to turn aside the Auscultatory signs from their most common object, and to make them point to another which is of very rare occurrence. Hence I am persuaded that the most experienced and most skilful physicians generally fail to form a just diagnosis in cases of Dilatation of the Bronchi, and seldom fail to form a wrong one; the Auscultatory signs and every attendant circumstance conspiring to lead them into error.

Chronic Bronchitis is the most frequent cause and concomitant of Bronchial Dilatation.

Now Chronic Bronchitis itself is often with great difficulty distinguished from Pulmonary Consumption. Its attendant emaciation, its copious puriform sputa, its abiding hectic, are all phthisical symptoms. And it is only after repeated examinations that we are able to exclude the idea of Phthisis when we find no Auscultatory signs of a cavity.

There is large Crepitation extensively diffused through the whole lungs, and that only; shewing that the copious puriform sputa come from the mucous lining of the Bronchi, and from it only.

But, suppose that in such a case there was Pectoriloquy withal, and Pectoriloquy in several places, or Gurgling Respiration and Gurgling Cough in several places, no human penetration could distinguish that disease from Pulmonary Consumption; and yet there might be neither tubercle nor vomica in any part of the lungs, but a dilatation of the Bronchi into the form of cavities.

A man, 46 years of age, had been liable to Catarrhs for several years, and for one year had suffered a slight habitual oppression of the chest. He had once spit blood in December of the preceding year. In the following February, upon the occasion of his contracting a fresh cold, an expectoration came on, which was copious and puriform, and very fœtid. Finally, a week before his admission into the hospital, he suffered a severe pain in the left side of the chest, which came on for the first time after his being wet through, and ever afterwards he was constrained to keep his bed.

He entered the hospital at the end of March. He was in a state of Orthopnœa, and his countenance expressed the greatest anxiety. He rejected, by an easy cough, a fœtid expectoration, consisting of yellow thick globules, mixed with a large quantity of serum, upon which they floated. The pain was so great over the whole of the *left* side of the chest, as not to allow the use of Percussion.

Auscultation found the Respiratory Murmur every where strong and clear on the right side, and much more feeble every where on the left; and on the left side, in the region of the mamma, and a little above the inferior angle of the scapula, there was a manifest Pectoriloquy.

Nobody entertained the slightest doubt in this case that the disease was Pulmonary Consumption, and that a vomica was formed. The patient remained in the hospital until his death,—nearly three months. In the meantime the pain of the left side, the fœtid expectoration, and the Pectoriloquy, all remained, to which, at length, Diarrhœa was added. It was remarkable that every evening he suffered a chilliness, followed by burning heat, but without perspiration.

Upon dissection, the left lung hardly crepitated at all, although it floated in water. In its upper lobe was a cavity large enough to admit a middle-sized nut, which contained a fluid of the same kind with that which was expectorated. A bronchial tube, as large as a goose-quill, entered into it; and dissection traced a continuation between the walls of the Bronchus and the walls of the cavity: in both the same mucous membrane red and thickened, the same fibrous membrane, and some traces of cartilaginous rings.

Here was no vomica, but nothing more than a considerable dilatation of a Bronchial tube. In the same lung several other Bronchial ramifications were dilated in the same way; suddenly they acquired three or four times their natural size, then contracted themselves again, and then enlarged again, thus in effect forming cavities. The pulmonary tissue between the dilated Bronchi was compressed as by pleuritic effusion *.

This case did not occur at St. Bartholomew's, but at La Charité; I was not the person deceived, but Andral: the possibility of deception, therefore, you will the more easily conceive. I have abridged the case from the "Clinique Médicale."

I am very far from saying that a just diagnosis of Bronchial Dilatation cannot be made during the life of the patient, or that Auscultation cannot contribute essential aid towards it; only I am persuaded that the physician must have very favourable opportunities of watching his patient, and that the case must be less complicated than such cases usually are, before he can arrive at it. The case, too, must be one in which the Bronchi are enlarged, still preserving their natural form, and not dilated into cavities.

But Laennec was led also by Auscultation to make inquiry into the nature of dilatation of the pulmonary vesicles; and this subject, as well as that of Bronchial Dilatation, he has made his own by the accuracy of his research.

The surface of the lung will sometimes present to the naked eye the same appearance which is given to it by an ordinary magnifying glass. The pulmonary vesicles will appear of the size of millet-seeds, or hemp-seeds, or raisin-stones.

The vesicles thus dilated sometimes preserve the level of the lungs, and sometimes transgress it a little.

This appearance results in part from the dilatation of single vesicles, and in part from the union of several, produced by the rupture of their immediate partitions.

Sometimes a transparent vesicle, as large as a nut-kernel, will rise very much above the surface of the lung, and seem to spring from a pedicle, or stalk. But this appearance is merely owing to its simple constriction just at the point of its emerging above the level of the surface.

Where the air-cells appear thus dilated at the surface of the lungs, the same condition is found to exist within. In order to see this condition in the lungs to the

* Andral, Clinique Medicale; Mal. de Poitrine, vol. i. 24.

best advantage, you should inflate them, and then let them dry. Afterwards, when you have divided them with a sharp knife, you will find, by examining the cut surface, that the air-cells are almost always more dilated within than they appear to be on the surface; and you will see, moreover, that of the air-cells some are simply dilated, and some are ruptured and united together. The smaller Bronchi sometimes partake of the dilatation of the air-cells to which they lead: but this event, which one would think likely to happen constantly, does in fact happen very seldom.

In a Lung, of which the air cells are dilated, there is something very peculiar to the touch. It has the feel of a downy cushion, not the crepitant feel of healthy Lung. It is softer than healthy Lung, and the same degree of pressure evidently displaces in it a larger quantity of air at once.

Now all this description belongs to conditions in which the air still remains within its proper vessels, those vessels being permanently and unnaturally distended; or distended and ruptured, moreover, into each other.

Hitherto I have abstained from using any name but what was necessary to the description. I have used none but *Dilatation of the air-cells or vesicles.* But this same Dilatation of the air-cells, in which the air *is still contained within its proper vessels*, is called by everybody Emphysema; and Emphysema let it be called; only take care that the misnomer does not convey an erroneous idea. I have no fancy for disputing about names; but this I would remark, that you might just as well call an Aneurism a Hæmorrhage, as a simple Dilatation of the air-cells, or the Rupture of the air-cells into each other, an Emphysema.

If an Aneurism bursts, then follows a Hæmorrhage; and if an air-cell bursts, then follows an Emphysema. And, in fact, distended air-cells often do burst, not into each other, but so as to allow the air to escape into surrounding texture.

One form of this Emphysema proper (as it may be called) is, when an air-cell bursts near the surface of the lungs, and air is effused beneath the pleura pulmonalis. Thus a vesicle of any size may be formed, from the egg of a sparrow to the egg of an ostrich, or even larger still. The air, now extravasated beneath the pleura, is capable of being displaced by pressure.

Another form of Emphysema proper, is described by Laennec; which I never saw. It is occasioned by rupture of distended air-cells; not on the surface whence air escapes beneath the pleura, but in the interior of the lung, whence air escapes into the pulmonary tissue and lacerates it, and forms a cavity in it.

The cavity thus formed is capable of receiving a moderate-sized nut. It is generally found about an inch deep beneath the surface of the lung. It is permanently blown up with air, and sometimes contains blood. The air-cells which immediately form the walls of the cavity are effaced, and do not retain their natural rounded form, either to the eye or the magnifier. But the air-cells at a little distance all around are still distended with air. The air, under these circumstances, is not necessarily effused into the interlobular structure; although it has escaped from its own vessels, it is still limited to this cavity.

There is one very curious circumstance attending this form of Emphysema. It is this: the pulmonary cavity, which is about an inch from the surface, being permanently blown up with air, exercises a great stress upon surrounding parts; under this stress they yield the more readily in that direction where there is the least resistance—viz. in the direction of the surface; and *there* a bump is forced up, correspondent in size to the interior cavity, and just over the part where it is situated.

The Dilatation of the Air-Cells has been explained to depend upon the forcible incarceration of air within them; and a cause capable of producing that incarceration has been found in Inflammation of the smaller Bronchial Ramifications which conduct them.

There is an affection called by the French "*Catarrhe Sec.*" It is characterized by habitual cough, or cough going and coming for years, and accompanied by little or no expectoration. But what expectoration there is consists of little pieces of hard, tough, pearly phlegm.

Upon this chronic affection attacks of a more acute kind are liable to be engrafted from time to time, accompanied by fever, and producing an increase of the expectoration; and when they subside, often leaving the habitual disorder worse.

In short it is one form of (what is called) Asthma; and the essential morbid conditions in which it consists are a congestion and thickening of the mucous lining in the small ramifications of the bronchi, and a secretion by it of this little glutinous pearly phlegm.

Now the congestion and thickening of the mucous membrane in that situation, and the residence of tough phlegm upon it, may be obstacles sufficient to prevent the easy return of air *from* the vesicles, while they may *not* be sufficient to prevent the access of air *to* them. The force of inspiration is evidently far greater than the force of

expiration; and the former is capable, moreover, of being augmented by an effort of the will, in a much greater degree than the latter.

It is not difficult to conceive how, more air being thus forced into the air-cells by each *inspiration* than each expiration can expel from them, there would result a constant imprisonment of air within them, and their consequent dilatation and their possible rupture.

I am, however, surprised that such congestion and thickening, and morbid secretion of the mucous membrane in this particular situation, should be insisted upon by Laennec as almost the sole cause of dilatation of the air-cells; for I suspect that all the ordinary mechanical impediments to breathing, whether within or without the lungs, have the common effect of raising hindrances and obstacles, *especially to the act of expiration*, and thus become capable of dilating the vesicles. It has occurred to me to witness their dilatation to the greatest extent, and their rupture and an extravasation of air beneath the pleura to the greatest degree, in cases of excessive deformity of the chest, arising from curved spine. I have found the same, of less degree and extent, in combination with tubercles and vomicæ; and I have found dilated vesicles, or ruptured vesicles, in clusters, at the edges of the lungs, where there has been no concomitant disease of the lungs to account for them.

And now for the auscultatory symptoms of Dilatation of the Air-cells, or of their Dilatation and Rupture together, as far as they have hitherto been described. These symptoms are of a very remarkable kind: they are derived both from Percussion and from Auscultation, but from neither singly. The positive intimations of the one are now in direct opposition to those of the other; yet do they point to the same thing and illustrate it *especially by their contrast*. Percussion gives a sound which is loud and clear; while to the ear, or the stethoscope applied to the same parts, either all is dull, and there is no respiratory murmur at all, or one rather suspected than distinctly audible. The chest does not give the same answer when you knock as when you listen.

Now it is not the clear sound upon Percussion that indicates Dilatation of the air-cells, or Emphysema; it is not the little sound, or the no sound, to the ear and the stethoscope, that indicates it. Either of them taken alone would denote something else; but *simultaneously*, they denote Dilatation of the Air-cells, or Emphysema.

There is nothing more interesting in the whole subject of Auscultation, than the various ways in which Percussion and Auscultation aid each other. They aid each other by their correspondent results, and they aid each other by their contrasted results. Each is thus made to go as far again by the help of the other, as it could possibly go alone.

Hitherto, in the course of our inquiry, I have spoken of Percussion occasionally only, introducing it to confirm the signs derived from Auscultation by its correspondent intimations. In inflammatory and tubercular diseases of the lungs, what Auscultation found pervious, Percussion found resonant; what Auscultation found condensed, Percussion found dull.

But now I introduce Percussion, not to confirm, by *its correspondent* intimations, the signs derived from Auscultation, but to rectify, by *its contradictory* evidences, what, if taken upon the sole attestation of Auscultation, would be false.

It is necessary for the sake of obtaining the full use of both these methods of appealing to the same sense in diseases of the chest, to understand them in their *disagreements*; to know *why* what one finds resonant, the other should find dull.

Percussion, by the resonance or non-resonance that attends it, *simply* intimates that air is or is not contained within the chest beneath that part of it upon which the Percussion is made. It intimates so much, and no more, with certainty. It gives no notice respecting any condition in which the air exists, or respecting any situation which it does or does not occupy. Whether it be moving about or at rest, there is the same resonance upon Percussion; whether it be contained in the bronchi, or in the air-cells, or in the cavity of pleura, there is still the same resonance, or so nearly the same, that no one would venture upon a diagnosis of its situation *merely* from a difference of sound elicited by striking the chest.

But Auscultation gives no intimations *absolutely* concerning the existence or non-existence of air within the chest. The air must be there under certain conditions for Auscultation to be able to detect it at all; for Auscultation to detect it, the air must be in motion. If it be at rest, Percussion can detect it, but Auscultation cannot. It must also be within the respiratory passages, or in situations with which they freely communicate; if it be beyond them, Percussion can detect it, but Auscultation cannot.

It is from air in these situations and under these conditions; from air in the respiratory passages, and from air put in motion by the act of breathing, that Auscultation conveys to us all the sounds diagnostic of so many varieties of

pulmonary disease. For, though air be still in the respiratory passages, if it be imprisoned there, and no motion reach it from the act of breathing, as in the case of dilated air-cells; or if it escape from the respiratory passages, as in the case of ruptured air-cells and emphysema beneath the pleura; then Auscultation can convey to the ear no sound, and is useless for the purposes of diagnosis.

But in this case Percussion still produces a resonance, and tells us (what is the fact) that there *is* air; yet Percussion does not tell under what circumstances or in what situation it is.

By comparison, however, and contrast of the results drawn from both methods, we arrive at conclusions in this case, to which neither could carry us separately. The chest is *resonant* to Percussion in every part, a sure evidence that in every part there is air!—but at the same time the chest is in *several* parts dull to Auscultation. Yet here is no contradiction to the fact that air is still in these parts: but upon comparison, it is a sure diagnostic sign that, being there, it is beyond reach of the respiration to give it motion; in short, that it is either imprisoned within the air-cells, or extravasated beyond them; and that we have to deal with a case of Dilatation of the Air-cells, or a case of Emphysema, or a case of Pneumothorax, of which I shall hereafter speak.

These, then, being the Auscultatory signs of dilated air-cells and ruptured air-cells, and of air extravasated out of its proper vessels, or (in one word) these being the signs of Emphysema, it would seem to be of easy detection. And existing *alone* and unmixed with other morbid conditions, it unquestionably must be so; but, in point of fact, it seldom, perhaps never, does exist alone.

There are certain conditions of parts frequently met with, which can hardly with propriety be called morbid. Although they are departures from what is natural and healthy, they exhibit no progressive morbid action. The blood-vessels are laying nothing down, and the absorbents are taking nothing up. There is only a yielding of parts to accommodate themselves to some pressing necessity, and a consequent change of natural capacity and size. The common biliary duct, from the passage of a gall-stone, the ureter from the passage of a renal calculus, dilates at the time, and remains dilated ever afterwards. So too the bowel, above the seat of a stricture, by gradually giving way to the pressure of its contents, will become permanently enlarged, and take the form of a pouch. These several states are all incidental to diseases, but are not diseases themselves.

The like conditions are exemplified, in the lungs, by dilatation of the bronchi, and dilatation and rupture of the air-cells, which grow out of preceding diseases, but hardly bear the character of diseases themselves.

But, although Emphysema may not itself come up to one's notion of what is understood by real disease, yet do real diseases constantly compass it round on every side. Diseases conduct to it, and diseases arise from it; and those that go before, and those that follow after, all remain and exist concurrently with it: so that I do not know any instances of more complicated thoracic affection than that of which Emphysema may, and generally does, form a part. There may be distortion or disease of the Dorsal Vertebræ; Chronic Bronchial Inflammation; Tubercular Depositions, or Vomicæ; any or all of these together, may have been concerned in imprisoning air within the vesicles, and so causing their dilatation or rupture; and having caused it, they still remain to augment it. Then there is the Emphysema itself; and, super-added to these, and arising out of one or all of them, may be dilatation of the right cavities of the heart.

Imagine what must be the complexity of symptoms from such complexity of disease! To omit others, think what the Auscultatory signs must be! For the Tubercular Cavities, the Bronchial Inflammation, the Dilated Heart, and the Emphysema itself, each have their own. And I do not say that you might not, from among all the rest, pick out the Auscultatory signs, which denote the existence of Emphysema. But if you did, it would be a great triumph of diagnosis.

There is (what is called) Interlobular Emphysema, in contradistinction to Pulmonary Emphysema, whose forms we have been considering.

Interlobular Emphysema is an extravasation of air into the cellular substance which intersects and separates the Pulmonary Lobules. This substance in its natural state is of so close a texture, that the infiltration of air into it could not have been thought possible. Yet the fact is certain. And then its real *cellular* texture becomes expanded and displayed. Thus lobule becomes separate from lobule, a space of half an inch or an inch being sometimes left between them, which is occupied by air that fills the intervening cellular tissue.

This tissue is more abundant and more cellular, and contains more air, as it is nearer the surface of the lung, and goes on

diminishing and containing less air as it penetrates deeper. Thus it is a good deal like the natural segments of an orange, which contains more juice just beneath the rind, and less as it approaches the centre.

From the manner in which the interlobular partitions run parallel to each other, it must be obvious that, when several are infiltrated with air at once, there will result a separation of various pulmonary lobules entirely from each other, like little islets.

When this interlobular Emphysema is near the root of the lungs, it soon reaches the mediastinum, whence air escapes into the cellular texture of the whole body.

Interlobular Emphysema, unlike the other forms described, has nothing to do with dilated air-cells: no dilated air-cells are found accompanying it, and where their rupture has taken place, cannot be traced. The pulmonary lobules, which are (as it were) blown apart from each other, and have air infiltrated all around them, are themselves in a healthy state.

The Emphysema from dilatation or rupture of the air-cells is a chronic affection resulting from causes which are tardy in their operation; but the Interlobular Emphysema takes place in a moment, and is the result of accident. Any violent effort which holds or intercepts the breath may cause it; the striving of parturition, the straining to unload the bowels, or to lift a heavy weight. I have myself seen it produced by the convulsive struggle of hooping cough; at least I presume so; for I have seen the subcutaneous cellular tissue about the neck of a child become blown up with air after a fit of coughing; but this happened before I had Auscultation to help me in inquiring the conditions of the lungs.

The Auscultatory signs of this Interlobular Emphysema are said to be such as cannot be mistaken, and strictly pathognomonic. They may be so; but I never had an opportunity of verifying them.

All this air effused must ensure a clear resonance upon Percussion. Then there are, besides, the "Frottement Ascendant" on Inspiration, and the "Frottement Descendant" on Expiration; and the "Large dry Crepitation." I wish I could determine the degree of certainty which belongs to these Auscultatory signs: but I cannot, having had no opportunity of investigating the circumstances of such rare cases.

There are many at this time who believe that the only way in which they can come at the knowledge of a theory is by destroying it, or taking it to pieces. This is exactly what children do with their playthings.—Hufeland.

IODINE, AND ITS POWER OF PRODUCING SALIVATION.

To the Editor of the Medical Gazette.

Sir,

I must, with your permission, once more trespass upon your columns, in order to reply to Mr. Horne's note. A more minute statement of the case referred to in my former communication, might have spared your pages both reply and rejoinder.

The patient in whom I observed salivation during the administration of iodine, had, I stated, taken that remedy for *five weeks* before the increased secretion appeared. The mercurial treatment had been relinquished *four months* before the commencement of this plan. During the interval no mercury had been given, the purgatives selected having always been either aloetic or saline. These particulars will, I imagine, be conclusive in proving that no substance previously given could have had a share in producing the effect.

I did not pretend to originality in my communication, merely wishing to corroborate Mr. Winslow's statement by the relation of a similar occurrence. In Johnson's journal for the current month, another instance is recorded to have been presented in the practice of Dr. Mackall, of Maryland; nor does the editor treat the fact as unprecedented. In your own journal may also be found papers, by Dr. Clendinning, in which the hydriodate of potash is stated in a few instances to have occasioned *severe* ptyalism, with affection of the gums, teeth, and breath. Dr. Mackall wished to account for what he saw, by supposing the iodine to have aided the *absorption* of mercury, which in his case had *immediately* preceded the remedy in question. This opinion, however, appears scarcely tenable, when we remember that it is the absorption of *living* molecules, not of other *medicines*, which is excited by iodine. If, then, calomel remained in the bowels, iodine could hardly promote its reception into the circulation; if already in the circulation, as seems more probable, then such assistance could not have been required. But Mr. Horne thinks, that though iodine cannot cause salivation *vi propria*, it yet does so by proving an "excitant to excite that action of the salivary glands which had not become previously developed." This is conceding the very point in question—I ask no more.

As to Mr. Horne's scepticism upon the power of minute doses of *calomel* to produce ptyalism, I presume he here stands quite alone. I do not, however, intend to

make any comments upon this part of his letter, being anxious to intrude upon your patience only so far as is necessary for replying to the question that he has addressed to myself.—I am, sir,

Yours respectfully,

GEORGE E. ELY.

Chatham, Jan. 5, 1836.

MORE SPECIMENS OF PHRENOLOGY.

THE heads of Lacenaire and Avril, the murderers who were lately guillotined, have been submitted to our examination. The forehead of Avril is very low, the facial angle acute, and those craniological developments are observed which indicate the thief and the assassin. But if in this instance the phrenologists may boast the truth of their system, in the head of Lacenaire they met with a stumbling-block not easily to be surmounted. Lacenaire, whose cold-blooded cruelty and want of feeling, under the most frightful circumstances, has astonished and disgusted all France, was phrenologically endowed with all the qualities of a good, kind, mild, sensible, and religious man, holding injustice and robbery in horror, and a hundred thousand leagues from being an assassin. This would be what we should be taught by phrenology, if we had not facts to correct the conclusions it would lead us to. Thus there is a marked development of all the interior and superior parts of the cranium, and as remarkable a smoothness of the two sides, and particularly in those parts which are said to correspond with robbery and murder. The organs of goodness and theosophy are remarkably prominent.—*Gazette Médicale.*

M. Leuret gives an account, in the *Gazette Médicale*, of a celebrated phrenologist of Paris, who, not long since, made a sad blunder. He selected a man-servant of an admirable *conformation*. Destructiveness, secretiveness, acquisitiveness—none; benevolence, conscientiousness—perfect; conscientiousness in particular was so well developed, that no body ever reckoned after this honest man; he was a model—as faithful as "man Friday." The phrenologist's wife, however, who wanted *faith*, soon found out our model of a servant to be an arrant rogue, and discharged him forthwith: upon which the husband, utterly unable to comprehend how these things could be, rubbed his eyes and was much confounded. But at last he discovered the cause. There must have been *transposition* of the man's *organs!* It was secretiveness that had usurped the place of conscientiousness—just as the heart is sometimes found on the right side, and the liver in the situation of the stomach. Good!

COLLEGE OF PHYSICIANS.

THE evening meetings will not commence this season quite so early as on former occasions. The first, we understand, will take place on Monday, the 22d February,—when Sir Henry Halford will read a paper.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By Jon. Pereira, Esq., F.L.S.

Lecture XVIII.

The order *Hemiptera* (ημι, half, and πτερον, wing), has received its name from the circumstance of some of the insects having elytra, one-half of which is coriaceous, or crustaceous; the other, or posterior half, membranous. But in a considerable number of hemipterous animals, the character just mentioned is wanting. To this order belongs the

Coccus Cacti.

History.—This insect was first brought into Europe in 1526, by the Spaniards, who called it *cochinilla*; a term which, according to Fee, is the diminutive of *cochon*, a pig.

Natural history.—One of the families of the order Hemiptera is denominated *Gallinsecta*, from the similarity of the females at one period of their existence to small galls. This family contains a single genus, *Coccus*, one species of which is the cochineal (*Coccus cacti.*)

The male cochineal insect is small, of a dark or bluish-red colour, and has a pair of snow white wings which cover the body longitudinally. At the posterior extremity of the body are two white caudal bristles, between which lie the genital organs.

The females are larger than the males, and without wings. Their bodies have the same dark or bluish-red colour, but covered with a whitish dust. The dorsal surface is convex; the abdominal, flat. They fix themselves firmly on the plant which serves them as a habitation, and never quit this spot: here they couple, and increase considerably in size. Each insect lays several thousand eggs, which proceed from the body through an aperture placed at the extremity of the abdomen, and pass under the belly, to be there hatched. Death then ensues; the body of the mother dries up; its two membranes become flat, and form a sort of shell or cocoon, in which the eggs are inclosed, and from whence the little cochineals soon proceed. The female only is of commercial value.

Cultivation.—The cochineal insect is a native of South America, and is domesticated and reared with the greatest care in Mexico. It feeds on a plant called the *Opuntia cochinillifera*, or the *Nopal* (fig. 87.)

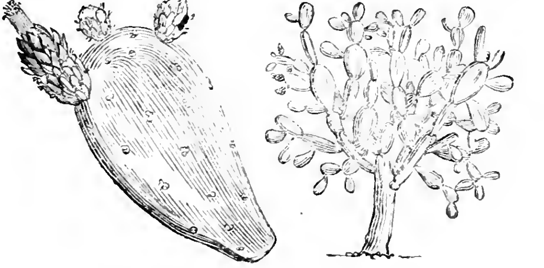

Fig. 87.—*Opuntia Cochinillifera.*

Plantations of these are cultivated for the nourishment of the insects. Here the impregnated females are placed; this operation being denominated *sowing them.* Young ones are soon developed; and some months afterwards, when the females have become fecundated and enlarged, the harvest commences. The insects are brushed off, and killed by immersing them in water, by exposure to the sun's rays, or in the vapour-baths of the Mexicans.

Three harvests are made annually: the first being best, since the impregnated females alone are taken; in the second the young females also are collected; and in the third both old and young ones, and skins, are collected indiscriminately. Before the rainy season commences, branches of the nopal plant, loaded with infant insects, are cut off and preserved in the houses of the Mexicans,; the animals would otherwise be destroyed by the weather.

Commerce.—From one district of Mexico alone (Oaxaca), the annual exportation of cochineal has been estimated at 500,000*l.* The annual importation into this country is calculated in some books at 150,000 lbs., worth 275,000*l.*; but this statement is overcharged. I find by reference to the Custom-house "Trade List," that for 1834 and 1835 the duties were paid for the following quantities:—

	lbs.
1834	100,292
1835	135,235

The value of this (in bond) varied from 6s. 9d. to 9s. per lb., to which 6d. per lb. is to be added for duty; so that if we call the average importation 120,000 lbs., at 10s. per lb., the value will be only 60,000*l.* On an average one pound of cochineal contains 70,000 dried insects, so that the number of these consumed annually in Great Britain is, at a moderate calculation, 8400,000,000!!

Physical properties and varieties. — Two kinds of cochineal are distinguished in commerce, the silver and the black.

1. *Silver cochineal.*—This has a purplish grey colour; but in all the furrows and depressions we observe a whitish powder, which, examined by the aid of a lens, appears like fine wool; it is considered the best kind, and is called by the Spaniards the *Cochinilla jaspeada.*

2. *Black cochineal* has a dark-brown colour, and is termed by the Spaniards *Cochinilla renegrida*, or *grana nigra.*

Both kinds are about one or two lines long, yield a dark-red powder, are inodorous, and have a bitterish warm taste, tinging the saliva violet-red. In burning they evolve an animal odour, and leave a greyish-white ash. By infusion in water they swell up, shew their ringed character, and even their feet, giving the liquid a red colour.

Purity.—The goodness of cochineal is determined by mere inspection. The silver variety is usually preferred, and hence it is sometimes imitated by shaking the black variety in bags with powdered talc. A magnifying glass will, however, readily distinguish the little plates of talc from the woolly character of the silver cochineal

Chemical properties.—Two analyses have been made of cochineal; one by John, the other by Pelletier and Caventou.

Analysis by Pelletier and Caventou.

Peculiar animal matter.
Fatty matter, composed of stearine and elaine.
Odorous acid.
Carmine.
Salts (phosphates of lime and potash, chloride of potassium, and carbonate of lime.)

The colouring matter called here *carmine*, is that which John denominated *cochenillin.* The following are some of its properties:—

It is a purplish-red substance, unalterable in the air, very soluble in water, soluble in alcohol, but insoluble in æther and oils (fixed and volatile). Its colour and solubility are variously affected by combination with different substances. Thus chlorine and iodine render it yellow. Acids do not precipitate it, but lighten its colour, and, in fact, make it yellowish. [The action of gallic, sulphuric, and nitric acids, on an infusion of cochineal, was here shown.] Alkalies and salifiable bases deepen its colour, and change it to violet. Some of its compounds with bases are soluble, others not. Its affinity for the hydrate of alumina is most powerful: if a solution of alum be mixed with an infusion of cochineal, and then potash or ammonia added, the alumina is thrown down in combination with the carmine, forming what is termed a *lake.* A number of salts act on it: thus the acetate of lead and protochloride of tin form precipitates with it, the first violet, the second red-coloured. Some salts, as the chloride of gold, change the colour of the solution, but do not cause a precipitate. Muriate of iron darkens the solution.

Physiological effects and uses.—Cochineal has been said to be diuretic, sudorific, antispasmodic, and anodyne, but without the least proof. A mixture of salt of tartar (potassæ subcarbonas, Ph. L.) and cochineal is a popular favourite in hooping-cough. The only real value of cochineal

is as a colouring matter, for which it is employed both in powder and solution.

HYMENOPTERA.

The order *Hymenoptera* has received its name from the membranous character of its four wings (υμην, membrane, and πτερον, wing); in this respect, however, it agrees with the order Neuroptera. But in the former the nervures of the wings divide and subdivide, like blood-vessels, while in the latter they form a kind of network, or lace. The only hymenopterous insect which I shall notice is the bee, or

Apis Mellifica.

History.—This animal was very anciently known, and is frequently referred to in the Old Testament. In all ages it has been an object of admiration and attention, on account of its industry, curious economy, and policy.

Natural history.—The honey-bee is an animal too well known to require much description; it lives in societies, which are called *swarms*, consisting of from fifteen to twenty, or even thirty, thousand individuals. In a state of nature they reside in hollow trees; but they are almost universally domesticated, and are preserved in *hives*.

They undergo a perfect metamorphosis: the *ovum*, or egg, is milk-white, semi-transparent, and attached to an angle of the *alveolus*, or cell. In about three days the *larva* is developed, and lies horizontally in its cell, being supplied with food by the working bees. In about five days it attains its full growth, when the cell is closed up with wax, and the insect spins its silky cocoon, which occupies it from twenty-four to thirty-six hours; and in about three days it becomes the *pupa*, in which state it continues for about seven days and a half (more or less, according to the sex), and is then metamorphosed into the *imago*, or perfect insect.

In this perfect form, the animals possess the following characters:—They have visible mandibles and palpi, with four unequal wings, the nervures of which branch variously; thus constituting the hymenopterous insect. The females and neuters are furnished with a retractile *aculeus*, or sting. The first joint of the tarsi of the posterior pair of feet is very large, compressed, quadrangular, and furnished at its internal face with silky down. By means of this little brush, these animals are enabled to collect the pollen of plants. The colour of the animal is blackish; the abdomen having a transverse greyish band, formed by the down at the base of the third and following segments.

Each society, or swarm, is composed of three classes of individuals — namely, a female, males, and neuters. 1st. The female, commonly called the *queen bee*, is narrower and longer than the others. 2dly. The males are termed *drones*; and in each hive there are from 800 to 1000: in size, they are intermediate between the female and the workers, and are not provided with stings, like the others. Towards autumn, when they can be of no further use, they are destroyed by the neuters. 3dly. The neuters are commonly termed *working bees*, and are by far the most numerous, since in each hive there are from fifteen to thirty thousand. Though termed neuters, they are in reality to be regarded as females, whose ovaries are not devoloped, in consequence, as some have supposed, of the nature of the aliment with which they are supplied while in the larva state.

On the *internal organization* of these animals I must be very brief. The *respiratory* system consists of ramified tracheæ, as in other insects. The *alimentary canal* is composed of an œsophagus (which enlarges at one part, forming the *crop*, or sucking stomach), a proper stomach, and small intestine, which terminates in the large intestine. The *biliary vessels* open immediately behind the stomach. The *salivary system* is very highly developed, the common canal of which opens into the proboscis. The *nervous system* is similar to that of other insects, consisting of a part analogous to the cerebro-spinal axis of the vertebrata, and a single and double sympathetic system. The *male genital* organs are two testicles, each having a vas deferens which terminates in a vesicula seminalis: from the conjoined extremities of the vesiculæ proceeds a common duct, terminating in the penis. The *female genital* organs consist of two ovaries made up of tubes, each tube containing about twelve eggs: the two oviducts from these ovaries terminate in a vagina, into which also opens a duct from a roundish vesicle. The *poison apparatus* is found only in the females and neuters: it consists of two thin convoluted secreting organs, opening into a pyriform receptacle, from which a small duct passes to the sting, which consists of two portions placed side by side, barbed at the extremity, and contained in a sheath. [Drawings illustrative of the anatomy of the bees were shewn.]

The effects produced by the sting of a bee are pain, redness, swelling, and hardness of the part. If a swarm attack an individual, the consequences might be fatal. Those who have tasted the poison, declare it to be hot and acrid. The best mode of treating these cases is as follows:—If the sting be left within the wound, immedi-

ately remove it; then rub the part with the saliva, or with oil and hartshorn: some recommend honey as a local application.

Bees furnish two products useful in medicine—namely, wax and honey. The first constitutes the sides of the cells or alveoli of the honey-comb, in which the eggs and honey are deposited; the latter (the honey) is to nourish the animals during the winter.

Honey.

Production.—Honey is secreted by the nectariferous glands of flowers, and is collected by the working or neuter bees, who take it up by suction, or lapping, and pass it into the dilatation of the œsophagus, denominated *crop*, *sucking stomach*, or *honey-bag*; beyond which, we presume, the honey does not pass, as it has never been found in the true stomach. When the animal arrives at the hive, the honey is disgorged by a kind of inverted peristaltic motion, and is probably somewhat altered in its properties by the secretions of the crop.

Physical properties.—Honey varies in its taste and odour according to the age of the bees, and the flowers on which they have fed. A hive which has never swarmed is considered to yield the best, which is, therefore, called *virgin* honey. The flavour of Narbonne honey, which is so much admired, is said to arise from the labiate flowers on which the animals feed; to imitate this, a sprig of rosemary is sometimes added to the honey obtained from other places.

Purity.—Flour, it is said, is now and then mixed with honey. It may be readily distinguised by its insolubility in cold water, and by the blue colour produced by the addition of iodine.

Chemical properties.—The constituents of honey vary somewhat according to the food of the bees, the season, the age of the animals, the mode of extracting it from the combs, &c. It must, however, be regarded at all times as a concentrated solution of *sugar*, mixed with *odorous, colouring*, *gummy*, and *waxy* matters. The saccharine matter is of two kinds: one crystallizable and analogous to the sugar of grapes; the other incrystallizable, and similar to the uncrystallizable brown syrup of the sugar-cane. Guibourt has found also mannite, which differs from sugar in not fermenting when mixed with water and yeast.

Physiological effects.—I have already more than once referred to the variable qualities of honey, arising from several circumstances, the most important of which is, the nature of the plants on which the bees feed. To this circumstance is owing the good quality and flavour of honey of certain districts: thus the environs of Narbonne and Mount Ida, in Crete, yield honey of the best quality, owing to the great abundance of labiate flowers. On some occasions, honey has been found to possess poisonous properties, arising (as is supposed) from the bees collecting it from poisonous plants. In Xenophon's account of the "retreat of the ten thousand" this celebrated general tells us, that some of his soldiers having eaten honey, in the neighbourhood of Trapezus (now called Trebizond), were seized with vomiting and purging, and became delirious, but that none died. Tournefort, who visited this part of the world more than 2000 years subsequently, ascribes these poisonous properties of the honey to the bees feeding on the *Azalea pontica*, which covers the mountains of this part of the world. Bees are said to gather poisonous honey from *Allium ursinum*, and, on the Alps, from *Aconitum lycoctonum*. In America, Augustus St. Hilaire found poisonous honey which had been collected by a species of wasp.

Disregarding these occasional and remarkable effects of honey, we may consider this substance as usually being, in its local operation, demulcent and emollient, while its constitutional influence is that of a nutrient. Its glutinous character renders it sheathing, or emulcent; but it has besides a relaxing or emollient action, shown by its diminishing irritation in the parts to which it is applied. Its saccharine and mucilaginous constituents, of course, render it nutritive. It acts mildly on the mucous lining of the alimentary tube, promoting its secretion, and having thereby a laxative effect. It is very apt to excite indigestion and colic; effects which are said to be more especially produced by fresh honey, and to be less easily induced after clarification. As these phenomena are not constant, they may arise, in some cases, from particular conditions of the honey; but frequently they arise from peculiarities on the part of the patient, which are either accidental or constitutional.

Uses.—Honey is frequently employed as a topical agent. Thus it is a popular application to promote the maturation of small abscesses and furunculi, for which purpose it is usually mixed with flour, and applied on linen or leather. It sometimes forms a constituent of gargles, partly on account of its taste, partly for its emollient operation; as a vehicle for the application of other more powerful agents to the mouth and throat, especially in children. As a demulcent and emollient, we sometimes employ it in internal diseases—as pneumonia and abdominal in-

flammation. I have sometimes found honey, mixed with barley water, to which a little of the juice and peel of the lemon are added, a very pleasant and useful demulcent, taken warm, to allay troublesome coughs.

Preparations (MELLITES).—Syrups, prepared with honey instead of common sugar, are denominated by the French writers *mellites.* They are semi-liquid, or viscous, and are usually made with clarified honey (*mel despumatum*)—that is, honey which has been melted and skimmed in a water bath. Mellites are of two kinds —simple and acid.

(*a*) *Simple mellites* are prepared by mixing powders or aqueous liquids with clarified honey: thus, the *mellite of borax* and *mellite of roses.*

(*b*) *Acid mellites* or *oxymels* are prepared by mixing acetous liquids with honey, as in *simple mellite* (or oxymel), and *mellite of squills.* Simple oxymel is sometimes employed in gargles,—sometimes as an expectorant.

Wax.

History and production.—Wax is an organic product, found both in vegetables and animals. In the former we meet with it either as a distinct layer, or in the form of a glaucous powder on the surface of the stem, leaves, or fruit. As an example of a *stem* secreting wax, I cannot refer you to a better example than the *Ceroxylon Andicola,* (fig. 88,) called also *Palma de Cera,* a tall palm of from 160 to 180 feet in height, which grows, as its name indicates, on the Andes.

FIG. 88.—*Ceroxylon Andicola.*

The stem (which is swollen in the middle) shows in its whole length rings, resulting from the fall of the leaves: the spaces between these are smooth, yellowish, and covered with a mixture of one part wax and two parts resin, which the inhabitants use for the manufacture of candles, &c. From the resin of this tree Bonastre has obtained a substance he terms *ceroxyline.* This resinous and waxy layer seems to occupy the place of an epidermis: the rings themselves being real cicatrices, are never covered with wax.

The South American tree called *Palo de vacca* (*Galactodendrum* of Kunth) yields a milky juice, which appears to be a waxy emulsion; so also the juice of *Asclepias gigantea.*

The *leaves* of many plants have a coating of wax, which in some cases gives them a glaucous, in others a varnished appearance. The substance called *chlorophylle* seems to be a kind of green wax, which is the source of the green colour of plants. Wax is also a constituent of the pollen of plants. On the surface of *fruits,* as the plum, it gives the appearance commonly denominated *bloom.* The fruit of *Myrica cerifera* yields nearly a quarter of its weight of wax: the berries are about the size of a pepper-corn. To obtain the wax, they are boiled in water, and compressed, by which it is squeezed out, and floats on the surface of the water, from which it may be skimmed off. In the United States of America, wax is thus prepared and employed for making candles. It differs from common bee's wax by its green colour.

In animals we find wax sometimes as an excretion, sometimes as a constituent of some of the internal parts. We are told that the larva of the *Cicada limbata* (fig. 89), or white wax insect of China, is covered with a waxy powder, which is communicated to the trees upon which these insects are found, and is collected by the natives, who hold it in high estimations a medicinal a substance. It is described in Donovan's "*Insects of China.*"

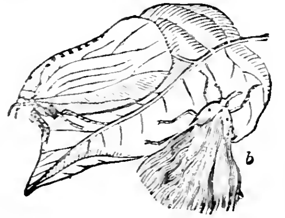

FIG. 89.—*Cicada limbata.*

Leopold Gmelin has found wax in the brain of man and of the ox.

Source of bees'-wax.—Bees-wax was at one time supposed to be merely the pollen of plants elaborated by bees. Bonnet, how-

ever, so early as 1768, asserted it to be a secretion from the ventral scales. Hunter and Huber have subsequently proved the correctness of this assertion. The latter writer, indeed, proved that the pollen is not at all essential to the production of wax, for bees fed on honey and water equally secreted it, and formed the usual waxy cells.

Preparation of yellow bees-wax.—The honey is extracted from the comb partly by allowing the latter to drip, partly by subjecting it to pressure. The comb is then melted in water, by which the impurities subside, and the wax is allowed to cool in moulds.

Properties of yellow wax.—Yellow wax has a remarkable and peculiar odour; its colour is more or less yellow, but varying in degree; its specific gravity varies from 0·960 to 0·965. It is said to be sometimes adulterated with suet, which gives it a fatty feel and disagreeable taste. Resin may be recognised by its solubility in cold alcohol; bean or pea meal, by its insolubility in oil of turpentine.

Wax bleaching.—To bleach yellow wax the following is the method adopted:—It is first melted (either in a copper vessel, or in a large vat or tub, by means of steam); while in the melted state it is drawn off through a stop-cock into a trough, called a *cradle*, perforated at the bottom with holes. This cradle is placed over a large water-tank, at one end of which is a cylinder, almost wholly immersed. The melted wax running through the holes in the cradle is allowed to fall on the top of the cylinder, which is kept constantly revolving on its axis, so that each stream of melted wax is solidified and converted into a kind of ribbon, and conveyed on the surface of the water to the other end of the tank. These ribbons of wax are here lifted out, and conveyed in baskets to the bleaching grounds, where they are placed on tables, and exposed to the air for one or two weeks (according to the state of the weather), being turned every day. The wax is then remelted, re-ribboned, and re-bleached; it is subsequently refined by melting in water acidulated with sulphuric acid.

Chlorine has been tried as a bleaching agent for wax, but it is said to render it harder and more brittle. I once tried this process, but could discover no alteration in the properties of the wax. Chevallier has employed animal charcoal; but the objection is the difficulty of separating the carbonaceous particles from the wax.

Properties of white wax.—Its colour is yellowish white; I have never met with pure wax perfectly white. The circular cakes of commerce, as well as wax candles, always contain spermaceti, which the dealers add to improve the colour. Pure wax is solid, brittle, inodorous, or nearly so, insipid, fusible, and at a much higher temperature decomposable. Its specific gravity varies from 0·8203 to 0·965.

Composition.—The ultimate constituents of wax are carbon, hydrogen, and oxygen.

	YELLOW WAX.	BLEACHED WAX.	
	Ure.	Gay-Lussac and Thénard.	Saussure.
Carbon ..	80·69	81·784	81·607
Hydrogen	11·37	12·672	13·859
Oxygen ..	7·94	5·544	4.534
	100·00	100·000	100·000

Wax is a fatty substance, and is composed of two principles, namely, *cerin* and *myricin*. The relation which these bear to each other, as well as to other fatty bodies, will perhaps be better understood by this table.

FATS
- saponifiable ..
  - by saponification yielding volatile fatty acids .... *Phocenine, Butyrin, Hircine.*
  - by saponification yielding fixed fatty acids
    - liquid at ordinary temperatures — *Elaine.*
    - solid at ordinary temperatures — *Stearine, Cetine, Cerin.*
- not saponifiable
  - but resulting from the saponification of other bodies .... *Æthal, Ceraine.*
  - not resulting from ditto .... *Ambreine, Myricine, Cholesterine.*

1. *Cerin.*—By reference to the preceding table, you observe Cerin is a solid saponifiable fat, furnishing by saponification fixed fatty (margaric, and perhaps oleic) acids. It is distinguished from Stearine and Cetin (with the latter of which it most closely agrees) by the products of its saponification.

Products of Saponification.

Of Cerin.	*Of Cetine.*	*Of Stearine.*
Margaric and Oleic Acids Ceraine.	Margaric & Oleic Acids. Extractiform Matter. Æthal.	Stearic Acid Glycerine.

Now you will observe that both cetine and cerin yield by saponification a peculiar fatty matter. That produced by cerin, and which has been called *Ceraine*, is distinguished from æthal, by its higher melting point (158°), and its less solubility in alcohol.

Cerin dissolves in 16 parts of hot alcohol, but is deposited as the liquid cools: in cold alcohol it is almost insoluble. It dissolves more readily in æther than in alcohol.

2. *Myricine* is distinguished from cerin by its incapability of forming a soap when mixed with alkalies. It is a white, fusible, solid, soluble in 123 parts of hot alcohol, and is deposited as the liquid cools.

The properties of cerin and myricine, however, require further examination, for Bucholz says myricine is softer and heavier than cerin, whereas John says it is harder and lighter. Some persons are of opinion these are not primitive constituents of wax, but formed in the process for procuring them.

Effects.—The local effects of wax are emollient and demulcent; the remote effects nutritive.

Uses.—It has been given internally, in the form of emulsion, in diarrhœa and dysentery, especially when ulceration of the alimentary tube is suspected. Hufeland and Wedekind, among the moderns, may be mentioned as persons who have used it in these cases. It has sometimes been employed as a masticatory, but its action is only mechanical.

Wax is, however, much more commonly used externally, sometimes as a mild sheathing or protecting application, sometimes as a basis for the application of other agents. It is a constituent of all cerates which take their name from it.

The vapour arising from wax placed on red-hot iron has been inhaled in phthisis.

Application.—The usual mode of exhibiting wax internally is by melting it, and forming an emulsion by means of soap, the yolks of eggs, or mucilage. Some recommend that it should be previously melted with some bland oil, as the oil of sweet almonds. The dose of it is from a scruple to two drachms.

We now arrive at the fourth and last division of animals denominated

Radiata, Zoophyta, or Cycloneura.

The animals of this division are called *Radiata*, from the form of their body. The term Zoophyta, sometimes used as synonymous with Radiata, is, however, only partially applicable. Dr. Grant calls this division the Cyclo-neura, from the particular form of the nervous system. The following are the classes which he admits.

	Classes.	Examples.
Radiata, or Cyclo-neura	1. Echinoderma	Asterias, or Starfish.
	2. Acalepha	Medusa.
	3. Polypiphera	Coral.
	4. Poriphera	Sponges.
	5. Polygastrica	Vibrio.

Polypiphera.

The polypipherous animals have received their name from the circumstance of their bearing tubes called *Polypes.* They consist of two parts, a skeleton, and a fleshy portion.

The *skeletons* vary in their consistence and nature, and also in their position relatively to the soft parts: thus, some are soft and flexible, others hard and calcareous. In the *Tubipora*, the skeleton is external, and forms a tube containing the fleshy portion of the animal: in the *Red Coral*, on the other hand, the skeleton is internal and solid, being cover-

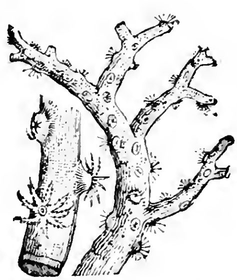

Fig. 90.—*Red Coral.*

ed externally by the soft flesh. In some of the polypiphera which have internal skeletons, the fleshy crust penetrates to some distance into the porous skeleton:—in these madrepores you have evident marks of this:—in red coral, on the contrary, you observe none of these calcarous cells.

The *fleshy* portion of the polypiphera may be external or internal. In either case there are developed from it fleshy tubes, each of which is surrounded at its external orifice with radiating filaments, called *tentaculæ*. The tubes called *Polypes*, are the organs by which these animals obtain their food, and are characteristic of the class.

Pharmacological Polypiphera.—The calcarous internal skeleton of several polipipherous animals, as the red coral (*Corallium rubrum* seu *Isis nobilis*) and the *Madrepora oculata*, were formerly employed in medicine. As they consist principally of the carbonate of lime, they offer no advantages over common chalk. The colouring matter of the red coral is peroxide of iron.

Poriphera.

The animals of this are distinguished from those of the preceding class by the absence of polypes. Dr. Grant has termed them poriferous animals, from the circumstance that on every part of their surface are found *pores*. As in the Polypiphera, we may divide the parts of which the Poriphera consist, into the skeleton and soft or fleshy parts. The *skeletons* consist of crystalline spicula (siliceous or calcareous) or of horny tubular filaments. The *fleshy* part consists of cellular tissue, which is so extremely soft, and the globules or cells of which have so little connexion with each other, that when the living animal is torn, the fleshy substance runs down from the lacerated parts like oil. On the surface of these animals we observe innumerable apertures or orifices; some are exceedingly minute, these are termed *pores;* others are considerably larger, and are termed *vents*, or *fæcal orifices*. The pores lead to canals which ramify throughout all parts of their texture, anastomose into larger and larger branches, and ultimately terminate in the fæcal orifices. It appears from the researches of Dr. Grant, that the water (containing the matters necessary for the existence of the animal) enters by the pores, circulates through the canals, and is expelled by the fæcal orifices, carrying along with it particles which separate from the sides of the canal.

Spongia officinalis.—This is the only poriferous animal employed in medicine. Its skeleton consists of horny tubular filaments, so disposed that they form a network. The fleshy substance is so soft, that when torn, it runs down like oil or the white of eggs.

This animal has been long known, though its nature was not perfectly understood; for a long time it was regarded as a vegetable substance. It grows in the sea, and is particularly abundant in the neighbourhood of the Greek islands.

Its principal constituent is a horny-like substance, which, according to Mr. Hatchett, consists of gelatine and coagulated albumen. Besides these animal matters, various salts are found in the ashes of sponge, such as the carbonate of lime and magnesia, phosphate of lime, iodide of sodium, &c.

Burnt sponge (*spongia usta*) has long been known and used in medicine. It has been employed in scrophula and bronchocele. Any benefit which may be derived from its use is referable to the iodine which it contains, and, therefore, it has now almost fallen into disuse. Burnt sponge lozenges, however, are still kept in the shops.

Burnt sponge should be prepared from unwashed sponge, for the washing removes a great part of the iodine on which the activity depends.

We have now finished the Animal Materia Medica, properly so called; but there are certain medicinal agents obtained by the decomposition of animal substances, which I think it necessary to notice,—namely, Hydrocyanic Acid, Ammonia, and Empyreumatic Oil.—In my next lecture I propose to examine the first of these.

REMARKS ON PARTIAL AMPUTATIONS OF THE FOOT AND HAND;

With Cases.

By John Macfarlane, M. D.,
Senior Surgeon to the Glasgow Royal Infirmary, &c. &c.

The propriety of attempting to save a part of the foot or hand, in cases of injury or disease, by having recourse to partial amputation, has been long known and acted upon, both in this country and on the Continent.

Garengeot, prior to the year 1720, when the first edition of his "Traité des Operations" was published, amputated a part of the foot for gangrene,

and recommends a similar procedure in every case to which it may be applicable. He also practised the removal of single metatarsal bones for caries, by a partial longitudinal, instead of a complete transverse section of the foot. M. Le Dran removed diseased metatarsal and metacarpal bones, with their corresponding toes and fingers.*

In the year 1636, Heurnius excised with success the cuboid and third cuneiform bones, shewing, at a still earlier period, that the principles which at present guide us in preserving sound portions of the foot and hand, were then understood and practised.† M. Moreau de Bar, in a case of diseased foot, excised the cuboid and third cuneiform bones, a part of the os calcis, and the posterior half of the fifth metatarsal bone.‡ B. Bell distinctly recommends amputation of the diseased parts alone, where all the metatarsal bones are not affected, even "should we be obliged to remove them all except one or two.§ Hey narrates a case of caries, in which he amputated the 3rd, 4th, and 5th toes, with their metatarsal bones, the greater part of the cuboid, and a small portion of the astragalus.‖ Sir Charles Bell describes the operation of excising metatarsal bones, and says "the careful and nice extraction of the spoiled bones from the hand or foot should be oftener done than it is."¶ Sir A. Cooper, in his valuable work on Dislocations, relates an interesting case of injury of the hand, where the fore-finger alone was preserved, which was afterwards found to be of great use to the patient.** Similar partial operations were also performed by Baron Larrey, in cases of gun-shot wounds. Guthrie recommends, in similar circumstances, the preservation, whenever it is practicable, of such of the metatarsal and metacarpal bones, with their toes and fingers, as may be uninjured.†† Hennen, whose authority is highly respectable, says, "cases will occur, where the hand or foot are only partially injured. By taking advantage of the joints and sound teguments, we may succeed in saving the limb*.

In the year 1823, Mr. Key, surgeon to Guy's Hospital, performed partial amputation in a very interesting case of injury of the foot. All the toes, with their metatarsal bones, except the great toe, were removed, along with the middle, external, and cuneiform bones, a sound flap having been obtained from the plantar surface of the foot.†

In this city, within my own observation, which extends to a period of more than 20 years, I know that when similar cases occurred, the practice has been adopted by almost every surgeon who officiated in our Infirmary, and by many private practitioners: and I have reason to believe that the importance of the treatment has been inculcated, and the different operations exhibited on the dead body, from year to year, to the pupils of our medical schools, by more than one of our surgical teachers. This statement will, I feel assured, be confirmed by the members of this society, many of whom have been connected with our Infirmary for years, and who, besides having had intimate acquaintance with the prevailing practice of the place, are so well qualified to estimate the correctness of these observations, and of others which are to follow. In fact, the propriety of the practice has been so long known, and so generally, I may say, universally, acted upon in this city, that many of the gentlemen who now hear me may deem these remarks and historical data superfluous. It does appear, however, in the authenticated notice lately published, of the last meeting of the British Association, in Dublin, as well as in some of the medical journals,‡ that Mr. Whatton, of the Manchester Infirmary, read a paper before the medical section, in which he seems to have claimed the credit of reviving, if not of originating, the operation of a partial longitudinal, instead of a complete transverse amputation of the foot; which assumption, it would appear, met with high approbation, and was received as a discovery so novel and important, that nothing less than a vote of thanks was proposed to, and actually bestowed upon, its pretended author.

I entertain a higher opinion of the Dublin surgeons, (some of whom were the loudest applauders of Mr. Whatton's paper) than to believe that they are ignorant of so important a part of surgical history and practice. The approbation which they seem to have bestowed on the author, on the living and walking specimen of his success which he produced, and on his casts, which they begged he would permit them to deposit in their Museum, is, I think, not to be attributed to ignorance on their parts, but to the national enthusiasm which pervaded the *native savans* on that memorable occasion, and which seems to have led them to greet with an Irish welcome all who came in the name, and for the purposes of science. It does not become us, however, who are sitting coolly at a distance from, and who were not exposed to the fascinating influence of the late scientific and festive scenes in Dublin, to allow the generous compliments of our Irish brethren, as to the novelty and originality of Mr. Whatton's operations, to pass altogether unnoticed. It is on this account that I have presumed to bring the subject before this society, being anxious to vindicate the surgical character of this city, and to show to others, that the practice of partial longitudinal amputation of the foot and hand, recently claimed as a novelty, has been followed amongst us for many years.

Instead of collecting, which a little trouble would enable me to do, an account of all the cases in which this mode of operating has been employed by the different surgeons in this city, I shall content myself with a short detail, interspersed with practical observations of such cases only as have come under my own observation.

I. Of the Foot.

It is of the utmost importance in fractures or caries of the metatarsal bones, if we desire to preserve in whole or in part the function of the foot, to remove only the injured or diseased parts, and to retain such as are sound. When partial amputation is required, we have been advised not to disarticulate the metatarsal from the tarsal bones, especially in the centre of the foot, but if the injury or disease will admit of it, to saw them across anterior to the articulation*.

* Boyer, Traité des Maladies Chirurgic., tome xi., p. 200.

Hey never attempted to take out a single metatarsal bone from the centre of the foot, partly from a fear of not being able to secure the bleeding vessels in a deep and straightened wound, and when caries existed, from an uncertainty as to the extent of the disease. The former objection is too trivial to be noticed; as to the latter, doubts may exist regarding the number and extent of the bones implicated, although this may generally be determined by accurate examination; in injuries, however, if the parts are examined before much tumefaction or tension has taken place, the number and extent of the fractures may be readily ascertained.

Case II.—*Caries of the Second Metatarsal bone, cured by Excision.*

J. W., aged 18 years, of a scrofulous habit, had a small spongy ulcer over the dorsum of the second metatarsal bone of the right foot, near its middle, which had originated nine months before I saw him, and was attributed to injury. The bone was found to be extensively carious; but in consequence of the diffuse swelling, from the infiltrated and indurated state of the integuments, some difficulty was experienced in ascertaining the condition of the neighbouring bones. After careful examination, believing that these were sound, I proceeded to remove the disease by dividing the metatarsal space on each side of the affected bone, from the separation of the toes upwards, disarticulating at the tarsal joint. The edges of the wound were easly approximated and retained in contact by a few broad straps of plaster and a bandage. In about three weeks the wound was healed, and soon thereafter the patient could walk without impediment.

When two or three of the metatarsal bones require to be removed, ought we to approximate the parts, so as to fill up the vacant space, or allow them to remain separate? As regards the hand, the propriety of accurate coaptation, in similar circumstances, cannot be doubted; but I am not satisfied that we will not obtain a more useful foot by allowing the toes to remain in their natural position. If we bring them together, which can only be done by force, we must partially displace the remaining metatarsal bones, causing them to approach obliquely at their free extremities, while at their base they are far

separated. We thus cramp and confine the movements of the foot, according to the true Chinese fashion, and of course narrow the surface upon which the patient must rest in walking.

These remarks suggested themselves to me some years ago, on examining the foot of a mechanic who had had the second and third metatarsal bones and toes removed, and the parts brought together, by the late Dr. George Monteath. There was then, and the last time I saw him there continued to be, a good deal of lameness, which I thought might have been less had the wound been differently managed.

If the disease is confined to the metatarsal bone of the great toe, which is the one most frequently affected with caries, either complete or partial excision will be required. Attempts to preserve sound portions of this bone, with the toe, should always be made, when practicable; because a greater degree of permanent lameness will result from the loss of the first metatarsal bone than from any of the others. It is necessary, however, that we should examine accurately the extent of the disease, and be satisfied that in removing a part of the bone all the caries is included, or the operation will prove unsuccessful. If the disease is confined to the distal third of the bone, this part may be excised, and the toe allowed to remain, with a prospect of its being useful; but if the middle or proximal thirds are removed, the chances of success are still greater, because the toe in a great measure retains its natural support. When it is found necessary to remove the bone entire, the corresponding toe should be also amputated, to prevent the lameness which, when preserved, it generally produces, becoming displaced and inverted by the irregular and uncertain action of its muscles and its detached exterior tendon.

Case II.—*Caries of the middle part of the First Metatarsal Bone cured by partial Excision.*

M. A., a delicate scrofulous woman, 21 years of age, was admitted into the Royal Infirmary on the 12th of April, 1832. Seven months previously, a small indolent tumor formed over the inner edge of the first metatarsal bone of the right foot, near its middle, which suppurated and gave rise to a fistula. Through this opening the bone was found carious, and so soft that the probe readily passed into its substance. The disease appearing to be confined to the centre of the bone, it was determined to remove this part alone, its two articulating extremities being left *in situ*. This was easily done by making a free incision in the direction of the toe, dissecting back the soft parts, and dividing the bone with the forceps, after having ascertained that all the unsound parts were included. After some suppuration which continued about three weeks, the wound was perfectly closed, and in a few weeks longer the power of the foot was fairly restored.

In very young subjects it is generally necessary to excise the entire bone, even should only a part of its surface be exposed and carious; because in them the cancelli, in which the disease often originates, may be more extensively softened and loaded with the cheesy deposit of scrofula than we can possibly ascertain by external examination.

Case III.—*Caries of the First Metatarsal Bone cured by Amputation.*

G. N., æt. 9, was admitted into the Royal Infirmary on the 15th September, 1831. Behind the ball of the left great toe there was a puffy swelling, and in the centre of this was a small fistulous opening which led to diseased bone. Twelve months was the duration of the disease, and its orign was attributed to a slight injury.

On the 18th an exploratory incision was made along the inner edge of the metatarsal bone, which was found more extensively diseased than the introduction of the probe, or the discoloured and tumefied integuments, indicated. The toe, with the entire metatarsal bone, was therefore amputated, which was done by extending the former incision back to the tarso-metatarsal joint, and around the root of the toe, then dissecting back the integuments, and disarticulating from the os cuneiforme. The cure was complete in about a month, but nearly a year elapsed before the lameness was removed.

When the caries is confined to one or more of the tarsal bones, and an operation is deemed necessary, it becomes a question of importance how far we are justified in removing the affected parts alone, without their metatarsal bones and toes. I confess my experience on this point has not been such as to ena-

ble me to give a satisfactory opinion. I have only once removed, in a case of injury produced by a heavy body falling on the outer side of the foot, two of the tarsal bones, the metatarsal bones and toes being allowed to remain. In this case the cuboid and third cuneiform were comminuted, and the integuments covering them extensively lacerated. With difficulty all the fractured portions were cut out; and after severe inflammation of the foot and leg, with copious suppurations, the wound closed. I lost sight of this patient before the utility of the foot in walking could be ascertained.

If the disease is confined to the cuboid, or any other tarsal bone, situated at the outer or inner side of the foot, excision will be more easily performed than when the central bones are affected. These are so deeply seated, and firmly wedged together, as to render their removal extremely difficult and painful. Nevertheless this has been sometimes had recourse to with success; but I suspect we will rarely meet with cases where the disease is confined to one or two of the tarsal bones, and where we can ascertain this by external examination. This was more easily and satisfactorily done in the following case than in any I ever met with.

Case IV.—*Caries of the Cuboid Bone, and of the anterior articulating surface of the Os Calcis, amputated with the 4th and 5th toes.*

A. M., aged 19, admitted September 12th, 1835. On the dorsum of the right foot, over the cuboid bone, there was an ulcerated opening the size of a sixpence, of an indolent appearance, with a good deal of surrounding tumefaction. The probe detected caries of the cuboid bone, and of the anterior articulating surface of the os calcis, the other bones being apparently sound. The ulcer had exexisted for seven months; but several years before this she had sprained her foot, and was afterwards subject to pain and swelling of the part.

After a variety of local treatment, which was totally ineffectual, I received the sanction of a consultation to amputate the diseased parts, which I did on the 13th of October. I commenced the operation by making a transverse incision in the dorsum of the foot, from the outer edge of the third toe, at its metatarsal joint, to the distal end of the metatarsal bone of the little toe. A corresponding incision was made in the sole; and at the junction of these two another was carried along the outer edge of the foot to the os calcis. The dorsal and plantar flaps having been detached as far as the third toe, it was found necessary, in order more effectually to expose the diseased parts, to make a transverse incision in the upper flap, opposite the calcaneo-cuboid articulation. The bistoury was then carried backwards, between the third and fourth metatarsal bones, and around the cuboid, which was removed with the fourth and fifth metatarsal bones and toes. The anterior articulating surface of the os calcis being destitute of cartilage, and in a state of caries, was removed by the cutting pliers, as was also a small rough portion of the external cuneiforme. Only one vessel, apparently the external plantar, required a ligature. Three points of suture were introduced, and the usual dressings applied.

On the 16th the edges of the wound were closely adhering; but on the 18th, a few minutes before the hour of visit, arterial hæmorrhage suddenly took place to the amount of fifteen ounces, which, however, ceased spontaneously, and did not return. The wound gradually healed, and when she left the Infirmary, about a fortnight ago, her foot was sound and neat: she had complete command of the motions of the remaining toes; and I have no doubt that in a few weeks longer she will be able to walk with little or no impediment.

Were I to meet with a similar case, in which the extent of the disease could be so distinctly ascertained, I would attempt the removal of the affected tarsal bones alone, leaving the metatarsal bones and toes, with their tendons. I am not prepared to admit that the toes thus preserved, from being deprived of their posterior support and connexion with the arch of the foot, would be of very great use in walking; still it is possible that the vacant space might be filled up; and as the toes and metatarsal bones could not be far displaced from their natural position, a more useful foot might in this way be obtained.

When all the anterior tarsal bones are diseased, a complete transverse operation is required. This operation, which receives the name of its author, Chopart,

has of late years had various objections started against it; such as the liability of the flap to slough when taken from the sole of the foot, the falling back of the stump, and projection forwards of the astragalus, by the action of the muscles of the calf, thus producing lameness; and in a case alluded to by Velpeau, requiring the tendo-Achillis to be cut*, and the supervention of high local inflammation and its accompaniments, by which the ankle-joint is sometimes involved, and a second amputation required. I have seen this operation performed frequently with success, and useful limbs preserved, without any of these untoward occurrences happening; and in two cases to which I particularly refer, the patients, by wearing a boot of a particular construction, were enabled to walk easily and comfortably.

Case V.—*Disease of the anterior Tarsal Bones—Chopart's operation successful.*

J. M'N., aged 10, was admitted into the Royal Infirmary on the 2d April, 1835, and came under my care on the 1st of May following. Four months ago an abscess formed on the dorsum of right foot, which was punctured, and gave rise to an ulcer of considerable size, through which several of the tarsal, and the proximal ends of some of the metatarsal, bones were discovered to be carious. The whole dorsum of the foot was inflamed, swollen, and had a doughy feel.

After the use of incisions, and a variety of other means both local and constitutional, the disease appeared to gain ground; and on a careful examination, it was believed that all the bones forming the two anterior rows of the tarsus were affected. Accordingly, on the 26th of May, and with the sanction of a consultation, I amputated the foot at the articulations of the calcaneum and astragalus with the cuboid and scaphoid bones. I made a semilunar incision with a small Lisfranc's knife, across the dorsum of the foot, about an inch anterior to the point where disarticulation was to be performed. I then transfixed the sole and made a large flap, by cutting down to the separation of the toes, after which the ligaments and remaining soft parts were readily divided. All the tarsal bones removed were carious, softened, and loaded with scrofulous deposits.

This boy was dismissed cured in a few weeks. The flexor and extensor tendons appeared to be adhering to the cicatrix, for he was able to move the point of his stump, and there was no tendency to its displacement from the preponderating action of the gastrocnemii muscles.

Case VI.—*Compound comminuted Fracture of the 4th and 5th Metatarsal Bones and Toes, and of the Cuboid and external Cuneiforme—Amputation.*

W. G., a robust and healthy man, 34 years of age, when assisting to raise a puncheon of spirits by means of a crane, the chain broke, and the end of the puncheon fell from a considerable height on the outer edge of the left foot, producing a contused wound, which extended from the outer edge of the os calcis obliquely forwards to the root of the third toe, with extensive comminution of the fourth and fifth metatarsal bones, and of a small portion of the cuboid and external cuneiforme. The plantar integuments being uninjured, I procured a flap there, which, with a smaller one from the dorsum, was nearly sufficient to cover the wound. The fractured bones and two toes were removed, and the parts dressed in the usual manner.

He had a smart attack of subfascial inflammation, commencing in the back of the foot, and extending to the knee, with high febrile excitement. These were subdued by incisions, leeches, cold lotions, and the use of nauseating doses of emetic tartar; but nearly two months elapsed before the wound was healed. When he began to walk, and for months after, he could not tolerate pressure over the remaining portion of the os cuboides. This was obviated by padding the outer part of his shoe; and the last time I saw him he walked with ease, and without lameness.

II. Of the Hand.

The majority of the observations which I have made regarding partial amputations of the foot will apply to the hand. There are, however, some peculiarities which I shall shortly notice.

* Médecine Opérat. tome i. p. 474.

In this city we are more frequently called upon to perform partial amputation of the hand for injuries than for diseases of the bones, being the reverse of what happens in the foot. We are also, in attempting to preserve a useful hand, more anxious than in the foot, by the accurate coaptation of the parts, to avoid deformity. This leads us, in amputating the middle or ring fingers, to remove at the same time the phalangeal end of the metacarpal bone, to allow the adjoining fingers to come into closer and more seemly contact. For the same reason, in removing one or both of the central metacarpal bones, we attempt to bring the parts into contact, and promote adhesion, instead of allowing them to cicatrize separately. I shall shortly notice two cases to illustrate the propriety of this practice.

Case VII.—*Caries of the metacarpal bone of the ring finger cured by amputation**.

A. M'S. aged 23, admitted September 27th, 1831. A year and a half ago received a blow on the dorsum of the right hand, which produced an abscess over the metacarpal bone of the ring finger. This was punctured, and a fistula established, through which extensive caries of the bone was discovered. As the swelling and discoloration occupied nearly the whole dorsum of the hand, it was with some difficulty I succeeded in ascertaining that none of the other metacarpal bones were affected.

On the 30th the diseased bone was removed, along with the finger to which it was attached, by transfixing the metacarpal space on each side with a French bistoury, and cutting down from the carpal articulation to the first phalanx. The sides of the wound were retained in close contact by sutures and a bandage; adhesion took place, and the patient was dismissed with a neat and useful hand, on the 21st of October.

The metacarpal bone was found on examination to be both necrosed and carious; its proximal half consisted of a thin shell which was lined with granulations, and contained a loose cancellated sequestrum; its distal end was softened, and loaded with pus.

* See Clinical Reports, p. 270.

Case VIII.—*Caries of the mteacarpal bones of the middle and ring fingers, cured by excision.*

E. G., a young unhealthy-looking woman, of a strumous habit, was sent to me from the Highlands, to have her hand amputated. She had been wounded in the back of the hand with a fork, about eighteen months before, which gave rise to extensive inflammation, and deep suppuration, the matter having been allowed to burrow in the parts without any incisions being made. At the time I saw her there were three ulcerated openings over the 3d and 4th metacarpal bones, filled with pale-coloured spongy granulations, through which, on the introduction of a probe, the subjacent bones were found extensively carious. The soft parts on the dorsum were much swollen, and it was not until after repeated and very careful examinations that I could ascertain the limits of the disease. When this was done, I did not hesitate to advise the patient to submit to partial amputation. The operation, as in the last case, was performed without any attempt to preserve a dorsal or palmar flap; the only difference was, that I divided the metacarpal spaces by cutting upwards from the division of the fingers, taking care to avoid the extensor tendons of the fore and little fingers, which, from their position, are very apt to be divided on approaching the carpus. The metacarpal bones were readily disarticulated from the os magnum and os unciforme, and with a little force, the parts were brought into contact: adhesion took place, and a neat hand was obtained, but it was not till several months had elapsed, that she regained free and useful motion of the remaining fingers.

The removal of the injured or diseased metacarpal bones, without their corresponding fingers, has been recommended and practised by MM. Troccon, Roux, Blandin*, Velpeau, Wardrop†, &c. This practice, I believe, is not generally followed, because the fingers thus preserved are frequently productive of annoyance and deformity.

In compound fractures, or dislocations of the carpus, when the injury is confined to one or two of these bones, they

* Dictionnaire de Medecine et de Chirurgie, tome ii. p. 269.

† Medico-Chirurgical Transactions. Vol. iv. p. 309

may be excised, and a useful hand preserved, but when the injury is more extensive, primary or secondary amputation will generally be required. In one case, I removed the scaphoid bone, which was dislocated, and projecting through a lacerated wound of the integuments, the injury being produced by a pistol bursting in the hand. This patient recovered the perfect use of his hand after protracted and extensive suppuration. In the following case, the injury was still more severe.

CASE IX.—*Compound comminuted fracture of the index, ring, and middle fingers, of the 4th and 5th metacarpal bones, and of the Os Unciforme.—Partial amputation.*

W. Y., a healthy young man, 19 years of age. When shooting in the country, on the 1st of January, 1827, his gun, which was overloaded and insecure, burst in his hands. Five hours after the accident, when I first saw him, the following was the state of the injured parts. The little, ring, and index fingers of the right hand were dreadfully lacerated, and their phalanges comminuted; the 4th and 5th metacarpal bones were fractured in several places, and projecting through lacerated openings in the dorsum and palm. The bones and tendons of the thumb and middle finger were uninjured, as also appeared to be the wrist-joint, although there was a good deal of swelling around it.

I proceeded to amputate the index finger at its metacarpal articulation, and then the 4th and 5th metacarpal bones, with the fingers attached to them. In the latter part of the operation, after dissecting off as much sound integuments from the palm and dorsum as I could procure, to cover the wound, I passed the bistoury from before backwards along the metacarpal space between the middle and ring fingers, till it reached the carpus, when its edge was turned out, and the two fractured metacarpal bones separated from the carpus. I then ascertained, for the first time, that the os unciforme, upon which the 4th and 5th metacarpal bones rest, was fractured into three pi ces, and partially displaced. These were removed, and the integuments, which nearly covered the wound, were approximated, and light dressings and a bandage applied. General and local bleeding, incisions, &c. were found necessary to subdue the very high constitutional and local disturbance which ensued. For some time the wrist-joint seemed in danger, but after free suppuration, and sloughing of a portion of the integuments, the swelling subsided, and the parts slowly healed. About a year after the injury, he was able to follow his employment, which was that of a tailor.

It were easy to add from private sources, as well as from the records of our infirmary, many additional cases to those I have detailed, in which partial amputation was successfully employed. I have said enough however, I trust, to convince every unprejudiced person, that in this city, we have long known, and justly appreciated, this very important, though certainly not novel, part of surgical practice.*

Glasgow, Jan. 1836.

ANEURISM—LIGATURE OF THE EXTERNAL ILIAC ARTERY—CURE.

To the Editor of the Medical Gazette.

SIR,

I BEG to forward to you, for publication in your widely circulated journal, the following case of aneurism, where the external iliac artery was successfully tied.—I have the honour to be, sir,

Your obedient servant,

EDMUND FURNER,
House-Surgeon.

Sussex County Hospital,
Jan. 20, 1836.

Daniel Kinch, aged 24 years, footman in a gentleman's family, of a plethoric habit, and very muscular frame, but unusually fat for so young a man, was admitted into the hospital on the 29th of last April, under the care of Mr. Tayler, with a crural aneurism on the right side. He had enjoyed robust health till within seven months of his admission: about that time, whilst carrying a heavy weight, his foot slipped, which compelled him to use considerable muscular effort to prevent falling. He, however, continued his occupation as

* At a numerous meeting of the Glasgow Medical Society, on the 15th December last, when the preceding paper was read, all the members who joined in the discussion fully and distinctly corroborated the statements I have made, as to the prevalence of the practice of partial amputations in this city.

usual, without being aware of having suffered any injury. Some time after he observed a small swelling in the right groin, which not being painful did not excite further notice. About four months from the time of his first remarking the tumor in the groin, he consulted Mr. Tayler, in consequence of general swelling of the right thigh and leg, attended with slight cutaneous erysipelas, and for which he could assign no cause. This, by rest and the application of cold lotion, was so far subdued that the limb was nearly reduced to its natural size. Mr. Tayler's attention was then directed to the tumor in the groin; and having ascertained its character, advised his immediately coming into the hospital, in order to undergo an operation.

At the time of his admission into the hospital, the tumor was the size of a hen's egg, situated an inch below Poupart's ligament, in the course of the crural artery, possessing very active pulsation: when firmly pressed upon, it could be partially emptied of its contents, but regained its original magnitude upon the pressure being removed. The circumference of the upper part of the thigh was four inches greater than that of the sound one, the limb below being increased in proportion. The integuments were of the natural colour; it was unattended with pain or inconvenience in walking; his general health was good, the heart's action regular, and the patient was wholly unconscious of labouring under a disease of importance. He was ordered spare diet, with purging and bleeding at intervals, as a preparatory measure, for three weeks, when he was considered to be in a favourable state for operation.

The operation of tying the external iliac artery was accordingly performed, in the presence of Messrs. Blaker and Lawrence, the other surgeons of the hospital, Mr. Stanley, of St. Bartholomew's, and several other professional gentlemen.

The patient being placed in the usual position, an incision, four inches in length, was then directed, more in the course of Poupart's ligament than is usually recommended. This was found greatly to facilitate the after-steps of the operation, from the increased space afforded by the more transverse division of the abdominal parietes. The peritoneum and intestines being held back by an assistant, the ligature was passed from within outwards, the sheath having been previously opened by cautiously scratching with the ivory handle of the knife. The ligature was a single strong cord of unbleached silk. Upon tightening it, the pulsation immediately ceased. The wound was brought together with adhesive plaster, and the patient ordered an anodyne draught. He complained of numbness in the foot for several days, but there was no difference at any time in the temperature of the limbs indicated by the thermometer. It is unnecessary to give a daily report of the case. The ligature came away on the sixteenth day; from which time he progressively improved, and was discharged August the 12th. The patient remained in the hospital until he was sufficiently recovered to resume his usual occupation, the tumor having almost disappeared. I have lately heard of him; the report was, he had never been in better health; the right limb quite as strong as ever.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'Alembert.

St. Thomas's Hospital Reports. By John F. South, Assistant Surgeon. No. I. *Nov.* 1835.

Our notice of our friends at St. Thomas's was cut marvellously short the week before last, some extracts which we had marked for insertion having been omitted sheerly from lack of space. But this was not the worst of it, inasmuch as we were made to promise the insertion of such portions of the brochure as might be calculated "to *entertain* our readers." The *devil*, no doubt, had a hand in this unlucky phrase; and yet was there no malice in it; we therefore crave pardon of the learned writers for our involuntary offence. The truth is, that finding there was no room for aught else, we wrote a short note to say that we should, at a future time, lay before our readers some portions which we thought would interest them; but as to charging such grave and learned parties with being *entertaining*, it is what we never should have dreamt of.

Mr. Travers has communicated largely to the "Reports," as has Mr. Tyrrell; but the only paper for any part of which we can even now make room, is that by Mr. Green, *On the Treatment of Hydrocele by Setons.* We shall extract one case, and the most important inferences drawn by the author from his general experience.

The following case is selected, not as a particularly favourable one, but because, being the first, the mode of introducing the threads is described more particularly than in the others:—

Thomas Waterman, ætat. 40, weaver, admitted into Isaac's ward, October 25, 1832. A healthy man, of regular habits: is the subject of hydrocele on the right side, which commenced, without any assignable cause, about five or six years since, and has gradually increased in size, but unaccompanied with pain.

Nov. 2d, 1 P.M.—The operation was performed as follows:—A trocar and canula having been introduced, about eight ounces of fluid were drawn off, and during this time the man fainted. The canula still remaining in, a needle six inches in length and as thick as a probe, with a trocar point at one and an eye at the other end, was introduced, armed with twelve threads of ordinary seton silk, into the canula, and having been carried upwards, perforated the tunica vaginalis and integuments near the upper and fore part of the swelling, and was drawn out by that aperture. The canula was then removed, and the ends of the thread tied loosely together over a space of about two inches. After he recovered from the faintness he was sent to bed, complaining of great pain extending up the cord to the loins.

10 P.M.—The pain had become so severe, that the threads were removed, and he soon began to experience relief.

3d.—Has had a restless night; the pain still continues, but is not so severe. His bowels being costive, mist. senn. comp. was ordered.

4th.—Slept better last night, the pain having subsided during the course of the evening; bowels open; complains of thirst; pulse soft and quick; has no appetite. There is slight heat and redness of the scrotum.

5th.—The swelling of the scrotum increasing, but the heat much diminished.

6th.—The scrotum is now as large as it was prior to the operation.

9th.—Much the same.

26th.—Since the last report the swelling has somewhat increased in size, but in other respects he was quite well.

Dec. 7th.—Fluctuation being now apparent, though there is no transparency in the tumor, the hydrocele was tapped a second time, and about six ounces of very dark-coloured fluid evacuated; this high colour, together with the great thickening of its coverings, which has occurred since the last operation, has been probably the cause of the opacity of the swelling. Threads were then introduced as before, and the patient sent to bed.

8th.—Has slept four or five hours during the night. There is considerable redness, but not much heat, about the scrotum this morning; has pain extending along the cord when pressed; the lower part of the scrotum very tender, and he complains of pain in the loins. Pulse quick and soft; skin moist.

1 P.M.—The threads were withdrawn after *twenty-two* hours.

9th.—Passed a rather restless night. The swelling a little increased, accompanied with redness; much heat and pain upon pressure.

11th.—He has slept well; bowels open; pulse regular and quiet. The swelling much the same, but the redness rather less, and he feels himself easy.

Jan. 5th, 1833.—The swelling much diminished. Adhesion has taken place at the lower, though there is still some fluid at the upper part.

Feb. 5th.—Was discharged. For some time previous to his leaving the house, he rubbed ung. iodinæ on the scrotum, which certainly caused partial absorption of the remaining fluid.

* * * *

The foregoing cases are intended as illustrations of a plan of treatment, which, although not altogether novel, may, perhaps, be deemed an improved method of effecting the radical cure of a hydrocele.

The object of the radical cure is that of causing such a change in the tunica vaginalis as will prevent the re-accumulation or re-production of the fluid. I use the term "change" advisedly; for though it is generally stated that the object in a radical cure is to obliterate the cavity of the tunica vaginalis, by causing adhesion of the sides of that membrane, a preparation in the collection of this hospital exhibits a tunic, taken from a person in whom the radical cure was effected by injection, and in whom, after this operation, no fluid was re-produced, with the cavity as perfect as it might be in the healthiest person. Here the change must have been produced by some alteration of the surface; and I can very well conceive that a slight inflammatory action may take place, so as to close the exhalant arteries, and to prevent them

afterwards from pouring their secretion into the cavity, or, at any rate, so as to close a sufficient number of them to prevent any redundancy of the secretion. I very strongly suspect that in many instances of the radical cure of hydrocele no more has been done than you see in this preparation; and, indeed, I think you will agree with me, that if we could always hit the production of that quantity of inflammation which should produce this, and no more, it would be a better plan of treating the complaint than that of causing the obliteration of the cavity. But unfortunately, under all the plans of treatment hitherto adopted, the quantity of inflammation cannot be regulated; unless, indeed, in the cases above cited, a method is offered which may, in some measure, supply the defect, and aid us in adjusting the requisite degree of inflammatory action.

* * * *

Now, generalising these facts, the results of the above and other cases, I may venture, perhaps, to say that the plan of treatment is well adapted to answer the end for which it was intended. In two instances, indeed, the operation failed from the want of a sufficient degree of inflammation, but which simply depended upon the insufficient irritation of the seton threads.

In another case there was a slight suppuration of the cellular membrane of the scrotum, which, however, only interfered with the rapidity of the cure, but was in no other way detrimental to the patient. In another case, however, there was excessive inflammation and a suppurative process in the tunica vaginalis; and the possibility or probability of this occurrence is perhaps the most serious objection to the operation proposed which may be gathered from these cases. It might, indeed, raise in the mind a doubt on the principle itself of the operation. You introduce an extraneous body into the tunic, and you allow it to remain till inflammation is produced, and it is possible that the inflammatory action excited by extraneous bodies may tend to the suppurative instead of the adhesive form of inflammation. As, however, this result was only observed in one case, and as no such disposition was manifested in a number of cases, of which the success was perfect, we are perhaps warranted in drawing a conclusion generally in favour of the effects of the seton. Of course future cases (and as I shall continue to adopt the same plan of treatment such will not be wanting) will decide the point; but otherwise, in respect of having a mode of treatment enabling us to regulate the degree of inflammation, the plan here offered presents great advantages.

I should state that the requisite degree of inflammation is one which is attended with the ordinary symptoms of that process; that is to say, pain, heat, swelling, some redness, and some constitutional affection. There should be, I think, some affection of the pulse, some indication of febrile action in the system, before the seton is withdrawn. As soon as this has been observed, the threads may be removed, and I believe that you may then expect that you have excited inflammation enough to cure the disease. So that it is not whether the seton has remained in ten, twelve, or twenty hours, for this must be regulated by circumstances, but it is whether the requisite degree of inflammation is produced. I should say that twenty hours was about the average time for the seton to remain; but it will vary in different instances.

I might likewise observe that this plan of exciting inflammation by a seton will answer your purpose in various other cases. Ganglions, which you cannot get rid of by bursting them under the skin, or by puncturing them with a surgical needle, and which it would be dangerous to remove, also enlarged bursæ, may be treated by a seton in the same way. Inflammation being excited, and the surfaces of these cysts brought into contact, you obtain adhesion and cure the disease;—I have done it repeatedly. I might speak of its efficacy too in that case which by some has been called hydrocele, or dropsy of the thyroid gland. I was consulted respecting a large swelling in the neck of a lady, which was evidently situated in the thyroid gland. I found that she had had a great deal of surgical advice, and that many plans had been adopted but without success; I had no inducement, therefore, to go through the same routine of remedies. On making an accurate examination, it appeared to me quite clear that there was a cyst containing fluid; and considering it a fit case for the use of the seton, I introduced a canula, by means of a trocar, for the discharge of the fluid. I then carried a seton through the cyst, and allowed it to remain till what I considered a requisite degree of inflamation had been produced. The result shortly was, that she became completely cured, and remains well to this day. So that this is a plan of treatment which may be adopted in cases similar to hydrocele, where you wish to excite adhesive inflammation, and where you wish to have some mode of regulating the degree of inflammation required.

CICERO.

CROWN AND ANCHOR MEETING.

WE must recur once more, however briefly, to the meeting of students at the Crown and Anchor, and some of the circumstances connected with that proceeding. The many letters we have received strongly confirm our views of the subject, and give us some additional information for which we were scarcely prepared. We regret we cannot find room for these communications—especially for those authenticated by the names of the writers: for one, however, (from an impartial observer), which reached us in good time, we have secured a place.

Our veracious contemporary, of course, makes a grand trumpeting of the affair, and chronicles the mighty deeds he has done. He claps his wings and crows at the thought of having had it all his own way; and even ventures to taunt the great body of the profession for not coming to support him. Is this stupidity or impudence? Knows he not that the fact of *his* intended presence, once announced, was sufficient to banish from the minds of men of any rank or standing all idea of participation in the proceedings—or of advocating the students' cause, which was already taken under such protection? Who were the advertised patrons of the meeting? Mr. Meade, the "grinder most aggrieved," filled the chair; and on the platform were seen the ominous visages of Mr. Wakley, *M.P.*, and his two friends, Messrs. Liston and Carpue. Need it surprise Mr. Wakley that nobody else was present—except the students, who were gathered principally to see the "rare monsters?"

In our last number we find we gave the meeting much more credit for orderly conduct than it was really entitled to. The report in the Lancet—revised as it was by the party who got up the entertainment — fully bears out most of what we have heard respecting the want of harmony which prevailed. Want of harmony is by far too mild a term to express the disunion, disputation, and almost open rupture, which, it seems, occurred. Some of our correspondents inform us of the vulgar and abusive language used by certain of the functionaries on the platform towards gentlemen who signified their dissent from what was going forward. Mr Meade's exhibition, we understand, was not of the most refined sort; well adapted, perhaps, "to split the ears of the *groundlings*," but eminently calculated at the same time, "to make the judicious grieve." Wakley talked the same sort of fustian which he has been in the habit of spouting forth and inditing for years back. But what said the worthy supporters of radical reform in medicine, Messrs. Liston and Carpue? Poor Mr. Carpue, "with his whitened locks," as his friend of the Lancet describes him, how gratifying it is to observe that his occupation is not yet quite gone, and that he still delights in the waters of agitation! His tirade on the College of Surgeons, for not electing on the Council "that great anatomist, unhappy Brookes," must have been very pathetic, edifying, and to the purpose: but we doubt if there was much occasion for informing the meeting, "with tears in his eyes," that the great Brookes died of poverty—"from absolute starvation." When he went so far, he might have told the whole of the story, and made a moral lesson of it to his hearers — it were better, we fancy, than many a tract from the Temperance Societies.

The report of our veracious contemporary puts a few words also into Mr. Liston's mouth, which enable us to form some idea of what it was he said, or attempted to say—for we sought that information in vain in other quarters. It was to the effect that he has now become a "staunch supporter of medical reform." Hear that, ye men of Edinburgh, who once enjoyed the valued presence of Mr. Liston, and never suspected that such a conversion could easily be wrought in him. Mr. Liston an advocate of reform! How curious might it not be, in this instance, to trace effects to their causes, and to ascertain what, besides "our prospects in London," could have produced this speedy change. "The present system," says this gentleman, "does not work well; and I hope that, in a little time, we shall have a much better one in its place." In what respect, might we ask, does not the system work well, so far as regards Mr. Liston? Is it possible that, in addition to the attractive influence of the *M.P.* of Finsbury, which brought the rest of the crowd to the meeting, there was any fellow-feeling between the surgeon of Gower-street and the worthy chairman? Was there any kindred grievance to be complained of? Had there been a recent rejection (a double one) of a candidate in Lincoln's-Inn-Fields, to irritate the feelings of the "celebrated surgeon" of the north, and all at once to drive him into the ranks of radical reform? Mark, we put the case interrogatively,—or hypothetically, if any one likes it better. Were we at liberty to speak all we know, we could readily, perhaps, assign the *true* cause for giving a holiday at Grosvenor Place, and hurrying off into Wakley's arms at the Crown and Anchor. But to return to the business of the meeting.

The getting up of a petition to be presented to parliament by Wakley was, of course, a grand object: and the *ruse* by which such a document was contrived, so as to appear to have the sanction of the Crown and Anchor assemblage, was at once ingenious and appropriate. No attempt was made on the part of the managers to procure the signatures of the students; they knew too well that that would show the feebleness of the whole thing; and the proposition that it should be otherwise, emanating from some non-contents, was immediately scouted. Thus the chairman procured the *privilege* to sign, in the name of the meeting, a petition which, were it exposed in the regular way for signature, would most undoubtedly not have had appended to it fifty names. But what could be more appropriate than that it should be signed by Mr. Meade himself, who in his own person combined the various characters of party chiefly aggrieved, chief patron, organizer, and *primo buffo* of the meeting?

It is gratifying to find that the whole proceeding has been denounced, not only by a large number of the steady and respectable students who attended the meeting out of pure curiosity, and were disgusted with the scene they witnessed, but by the pupils belonging to some of the large institutions, such as King's College, St. Thomas's Hospital, and Guy's. We refer our readers to the sensible resolutions (p. 704) passed by the St. Thomas's students, which contain a temperate disclaimer of participation in the Crown and Anchor affair, and at the same time point out the injustice of the cry raised against the Court of Examiners, without by any means subscribing servilely to the constitution or form of that Court. The proposal that, in the case of rejection, the candidate should have a right of *appeal* and a *public examination*, is not unreasonable, and is, we believe, sanctioned by the usage of some of the colleges in the United Kingdom.

ROYAL INSTITUTION.

Friday, Jan. 22, 1836.

Dr. Faraday on the Silicification of Vegetables.

THE series of evening meetings for the season commenced auspiciously, and to the great gratification of a large attendance of members and their friends, with an admirable lecture from Dr. Faraday. He began by calling attention to the leading properties of silica, its extraordinary intractibility when exposed to some of the most powerful agents—such as pure oil of vitriol, and muriatic acid—yet its solubility when in a certain state of combination with potash and water; its formation of a pasty substance in these circumstances, and again becoming dissolved by the addition of muriatic acid and water. The gaseous form of which it is susceptible, and the impalpable powder to which it may be reduced, were also noticed. But all this, rapidly and beautifully demonstrated, was merely preparatory to a description of the theories that have been proposed for accounting for the extraordinary change operated on vegetable bodies in certain localities. Some splendid fossil specimens were exhibited—in particular some stems of palm-tree, which were shewn to be identical in structure with the recent wood. Mr. Brown contributed largely to the rich supply of materials exhibited by the accomplished lecturer: so did Sir Francis Chantrey; and some fine microscopes for demonstrating the regular arrangement of the vessels in the silicified materials, were submitted to the inspection of visitors in the library. But, as Dr. Faraday said, how had nature operated these wonderful changes? It could not be by heat, for nothing in the original texture had suffered in the slightest degree, as it must have done under the influence of such an agent; it could not be by any ordinary or known solution of silica, for none such could possibly be injected into the delicate parts of a plant without destroying its finer tissues; nor did it seem likely that the process of nature was a tedious one, for the parts had evidently undergone a simultaneous alteration. In short, in the present state of our knowledge, all is doubt and difficulty on the subject; and the only theories which are in any way plausible, namely, those of Drs. Turner and Macculloch, have some insuperable objections to contend with. All the other operations of nature can, in a greater or less degree, be imitated by the ingenuity of the chemist; but there is a chemistry in the process of silicification which yet remains to be discovered,—some principle which, when known, will probably be recognized as a very simple one, however inscrutable and inexplicable it may be at present.

The conclusion of Dr. Faraday's discourse was an eloquent apology for the obstacles that render the path of discovery so difficult: if great discoveries could be attained with comparative facility, their charm and their value would perhaps be greatly underrated; many minor inventions, yet of great importance to society, would escape notice; and, above all, the collateral advantages arising from the discipline of the mind engaged in such investigations, would be totally lost.

CLINICAL LECTURE

ON

MEDULLARY SARCOMA OF THE TESTIS,

ON FRACTURE OF THE PATELLA, AND OF THE RIBS;

Delivered at the Westminster Hospital,

BY MR. GUTHRIE.

MEDULLARY SARCOMA.

THE preparation before you, gentlemen, is an excellent specimen of medullary sarcoma, or brain-like tumor of the testis; a malignant disease, which, in an advanced stage, is denominated, in general, fungus hæmatodes. I removed it some six weeks ago from a private patient, a young gentleman twenty years of age, and apparently otherwise remarkably healthy. Sir Astley Cooper saw him once with me, and I gave him half the testis, on the condition that he injected the whole: it could not, therefore, have been better done. When the tumor was first divided it looked like so much medullary matter replacing the testis and epididymis, the situation of which could not be distinguished. Hardened now, by being placed some days in alcohol, it looks as if the medullary matter had been formed in distinct lobules or cells of various sizes, and not in one homogeneous mass. It is not very vascular, although two or three parts are much more so than others, as you can readily perceive. The tunica vaginalis is adherent to the tunica reflexa, although it has admitted of separation at the upper part. It was neither inflamed nor adherent to the external parts.

The complaint began in the month of April, or rather was then first observed, in consequence of the testis being larger than the other, and as he had not received an injury, nor could attribute it to any other cause, he did not further advert to it, more particularly as he suffered no pain nor inconvenience of any kind, save from

its gradually increasing size, which made him, at the end of about five months, show it to his family attendant, who, after some little time, recommended him to apply to me. The right testis was as large as the closed hands, rather oval than spherical; the spermatic cord quite sound; and as the skin of the scrotum was loose and unaffected, the glands in the groin were free from disease, which I may say, by the way, only takes place in these cases when the external parts are implicated, their absorbents leading to the groin, whilst those of the testes proper go to the lumbar glands, a region in which they cannot be seen or felt unless they are much enlarged. There was no uneasiness in the back. The skin of the scrotum was as natural in appearance as it usually is when stretched over a large tumor. An experienced eye might detect perhaps a more general degree of vascularity, but it was not sufficiently observable to deserve special remark, and I allude to it because the increase of vascularity is sometimes supposed to be a well-marked symptom of this disease, and it is so at a later period of its existence or progress. The testes when poised on the hand gave a peculiar sensation as to weight which it is not easy to describe. It was heavier than serum or other fluid, and less elastic in its pressure. It was not as heavy as a solid mass of the same size composed of a different substance; and taken as a whole, as to weight and poise on the hand, it strongly resembled the sensations arising from a tumor composed of half hardened testis, half serum, firmly bound down upon it by the tunica vaginalis; and yet there was a something peculiar in it I cannot describe. When pressed by one finger it yielded a fair feeling of fluctuation, which did not appear distinct when two were applied in the usual manner at a short distance from each other, or on either side. It was then only soft and springy, but not yielding so as to cause a hollow to be visible, or to make any impression. These trials gave but little uneasiness, and grasping the whole with the hand and making pressure was not more felt, nor indeed so much as by a sound testis. I gave my opinion at once, that the disease was an incurable one, and would be malignant if the parts were allowed to remain. To convince the patient that it was not a fluid, as he supposed, I passed a small trochar into it, but nothing came through the canula but a few drops of blood. This satisfied me it was not a cystic or hydatid testis—a disease equally incurable, but never at any time malignant.

You will naturally ask me for a description of the cystic testis, but one disease is as rare as the other, and as difficult to detect or decide upon with accuracy. It varies only in a slight degree in external characters—in weight, poise, and the springy or false fluctuating feel—from the medullary disease I have described, but that slight degree brings it nearer to a hydrocele, from which it can only be distinguished in some cases by puncturing it. A fairly-educated surgeon—that is, one who has educated himself by diligent attendance on hospital or public practice, after the usual course of study has been gone through—will know that he has something more than is commonly met with to treat, and which an operation can alone cure, and he punctures in order to decide the point whether the swelling contains a fluid or not. It is needless to remark to you, that when a hydrocele is transparent a good surgeon does not want that information to enable him to detect the complaint, and the incapability of the tumor to transmit light is no proof that it is not a hydrocele, or a sac containing a fluid. A puncture with a lancet or trochar solves the mystery. If the case is one of cystic testicle a teaspoonful of fluid like serum escapes, and the discharge ceases. If a probe is pushed through the tube it meets with some resistance, which is easily overcome, and another teaspoonful is evacuated. The disease is a transformation of the whole testis and epididymis into a collection of cysts, each containing more or less of serous fluid, and the best comparison I can make of it when cut into halves, so as to render it intelligible, is to say it resembles a short thick bunch of green Portugal grapes that has been cut down the middle of the stalk, each grape, large and small, having been cut across, and the fluid, when the tumor is punctured, comes from each grape or cyst independently. The finest specimen of this disease I ever saw occurred in the case of an officer whose testis I removed some years ago. I gave Sir A. Cooper one half, the other is in the Military Museum at Chatham. This patient had no return of the disease any where, and I have already said it is not malignant, and relief is only obtained from its weight by removal, for it gives no other offence.

As nothing came through the opening I had made into the testis in question by the trochar but a little blood, I was satisfied it was neither a hydrocele nor a cystic testis, and that it could be nothing but a medullary sarcoma, or a pulpy testis, or, as it was anciently termed, a soft cancer, and that my first impression was correct.

I will not detain you further with any unnecessary particulars, but advert to what may be called the peculiarities of the case;

and I must here regret that I am obliged to speak of feelings and sensations which, although they may be, and are, quite clear to me, may be unintelligible in their niceties to you. I wish I could have shown you the case, and allowed you to have judged for yourselves. I have, in my simplicity or enthusiasm, which you please, asked several private patients to come down here and allow themselves to be shown to you. One gentleman promised to come, with a particular injury of the elbow, but he did not, and I lost my patient, for I never saw him again. You must therefore, gentlemen, make the most you can of what I have said, and I am always happy to find you asking questions which can lead to your instruction. When I can give you a salutary answer I am glad to do it, when I cannot I say so, and am as ready to learn as yourselves. It is stated by Sir A. Cooper, in his work on the diseases of the testes, and he has given proof of the statement being correct, that this disease (medullary sarcoma) begins with an enlargement which is at first accompanied with great hardness, like scirrhus. In this instance there was no hardness, but a gradual increase of size without pain (so says the patient, at least), and it is important to know that this disease, when it takes place without any accident or injury, does sometimes begin so quietly and so insidiously as to be observed only from the increase of the size of the part, without there being any thing peculiarly unnatural in it, which might otherwise attract particular attention. The young gentleman appears to have been in perfect health, and to have suffered from this disease without any apparent local or constitutional cause. Let us hope this is the case, and that he will not be so unfortunate as to have a reappearance of it in any other part of the body. The records or remembrances of surgery are imperfect on this point. When the disease is allowed to run its course, so that the veins of the scrotum become varicose, pains shoot through the part, the spermatic cord has become hard or irregular, the skin adheres to the parts beneath, or has even ulcerated, allowing a fungus to shoot forth bleeding on the slightest touch; an operation under all or any even of these symptoms has only delayed for a short time the evil hour of death. The disease has therefore been often considered an incurable one in all its stages, which I firmly believe not to be the case, and that if the operation is done at an early period success will generally follow its performance.

The last well-marked case of this disease I saw, and the result of which I know (for it is nothing to see a case unless the result is known,) was in the person of a courier, who received a blow from the saddle on the part, to which he attributed the occurrence of the disease; it was removed by Sir B. Brodie some five years ago in St. George's Hospital. The man is now alive and well. Sir Astley Cooper tells me the last case he saw, and in which the disease was removed, was two years ago, and the person is still alive and well. Mr. Keate, and most of my friends in the Court of Examiners of the College of Surgeons, and who are men of the greatest experience in London, can, I believe, all recollect a case or more in which, for some years, no re-appearance of disease took place; but unless these cases occur in private practice it is rarely that the subsequent history can be obtained, and hospital records and remembrances are therefore necessarily deficient. Let us hope, gentlemen, that we shall in time collect, through the medium of clinical remarks or otherwise, a body of evidence which will lead to the determinate result that the operation, if done sufficiently early, will generally, if not always, be successful. I am aware there may be a quibble about the words "sufficiently early," but we may with propriety consider these words to mean the absence of any marked symptoms beyond those I have alluded to as present in the case of the subject of our observations, for it is impossible for any one to know at what time the lumbar glands become affected; and I should be glad if any one could tell me why it is that they ever escape being affected after the disease has existed for a month, nay, even for a week.

We had a case in the old hospital to which I then drew the attention of the students in a particular manner, which might be mistaken for a medullary sarcoma by an inexperienced or inattentive person. The tumor was soft and pulpy, clearly not containing a serous fluid, barely fluctuating, but the skin was not natural; it was shining and soft, although not stretched, and was scaly, indicating the inflammation of a deep-seated abscess. An incision at the lower part evacuated a large quantity of a thick oily brown creamy fluid, and cured the patient. You should never remove a testis without examining it first by a large or deep-grooved needle, by puncture, or by an incision, for no man is free from error, and life is not long enough for any one to learn surgery thoroughly. So say, at least, the ablest I know in the profession.

TREATMENT OF FRACTURED PATELLA.

I have several times drawn your attention to two men lying opposite to each other in Northumberland Ward—one with a fractured patella, the other with a severe

crush of the chest between the wheel of a dray and the wall. The fractured patella I have treated without bandage of any kind. The man was placed on a fracture-bed, the two ends of which were raised so as to resemble the letter V, on the inside of which he lies, the toe of the afflicted side being as high as the head. The elevation of the foot and leg was not, however, sufficient to relax the rectus muscle unless the body was raised also, and it was only when this was done that the broken portions of bone came spontaneously into apposition. A month has elapsed since the accident, and the cure is surgically completed. It will be, however, three months yet before he will be able to use the leg; and even then the point of union, which is ligamentous, will stretch, without great care is taken to prevent it. In an exceedingly well-joined fracture I have seen the uniting substance stretch two inches after the patient had left the hospital, from the want of due precaution in the use of the leg—from, in fact, bending it too soon. The only point for observation in this case is, that the cure has been accomplished by position alone, and without the aid of any bandage.

FRACTURED RIBS.

The case of fractured ribs is not mine, and I cannot therefore say as much about it to you as I could wish. I have drawn your attention to it before, and I have thought it worth my while to visit the hospital every day to follow up the treatment. I hope you have all done the same. Am I right in supposing you have done so? The stethoscope has indicated daily the progress and the subsidence of disease, and I believe the man will get well. The only point I mean to comment on is, the application or non application of a bandage in a case of fractured rib. In this case a roller gave relief at first, but on Thursday last, when I saw him in passing through the ward late in the afternoon, he was in a good deal of distress in breathing, and I suggested to the house-surgeon the propriety of removing the bandage. This recommendation he adopted in the absence of his surgeon, and the man has been amending ever since. Sir W. Blizard was in the habit of saying that a bandage should never be applied either to a fractured patella or to the chest for broken ribs, in which latter direction he was certainly wrong. I have shown you, on former occasions, the great advantage as to ease and comfort to be derived from a bandage in certain cases; whilst in others, such as the present, it does harm. The truth and good practice lie *in medio*, and I am sorry to say I cannot give you a precise direction when you should resort to it—when not. You must ascertain the fact by a trial. I believe, but I am not quite sure, that a bandage is less useful when it compresses broken ribs to which the diaphragm is attached. It tends to prevent both of the ordinary ways of breathing. It was so in the present instance.

LECTURES

ON THE

DISEASES OF THE NERVOUS SYSTEM.

BY M. ANDRAL.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

HÆMORRHAGE OF THE NERVOUS CENTRES *.

Hæmorrhage of the Cerebellum; Analysis of thirty-two Cases, shewing that Paralysis generally occurs, and that Hemiplegia of the side opposite the effusion is its most common form—Hæmorrhage of the Spinal Cord—Various forms of Paralysis—Muscles of the Eye, Cheeks, Tongue, &c.—Cause of Paralysis—Lesions of Sensibility.

Hæmorrhage of the cerebellum.—This is not a very common complaint, and, so far as I know, only thirty-two cases of it have been published. Two questions naturally arise—1st, Does this form of hæmorrhage produce paralysis? and, secondly, On what side is the paralysis observed in those cases where it exists?

It is very difficult to decide these questions *à priori*, for, in fact, notwithstanding all the discussions upon the subject, nothing very definite is known with regard to the functions of the cerebellum,—and observation alone can enable us to solve the problem. If we would answer the question as to the seat of the paralysis from our first impression, anatomy would lead us to say that the loss of motion must exist on the same side as the organic lesion, because the *corpora restiformia*, which unite to form the cerebellum, do not interlace in the same manner as the anterior pyramids; but this anatomical reason, derived from the presence or absence of crossing in the fibres, has been combatted in the former lecture, in speaking of paralysis of the face. Here, in hæmorrhage of the cerebellum, the paralysis is on the opposite side, just as with regard to the brain.

---

* By an oversight, the general heading of the last lecture, page 616, was "Inflammation of the Spinal Marrow," instead of the above.

Let us now proceed to examine the cases which have been placed on record. I have already done this in the fifth volume of my Clinique; but since the last edition of the work the facts have accumulated, there being, as I have already said, thirty-two such on record. In twelve of these the details are not sufficient to enable us to say whether there was paralysis or not: we are merely told that there was a violent attack of apoplexy, rapidly terminating in death. In these twelve cases the lesion was found seven times in the middle lobe. Six of them belong to M. Serres, and are to be found in the second volume of his Anatomy of the Brain; the seventh is recorded by M. Dance, in his Memoir on Acute Hydrocephalus; three others consisted of hæmorrhage into one of the lateral lobes. I also have published a case of hæmorrhage into one of the lateral lobes, but the individual was not seen till after death. Another case belongs to Dr. Abercrombie: there was effusion into the right lateral lobe; there was constant coma; nothing is mentioned with regard to the movements; death at the end of forty hours. Two other cases presented simultaneous effusion into both lateral lobes; the first is altogether deficient in details, the last is contained in the work of Morgagni. There was hæmorrhage of both lateral lobes; the patient was found dead, with the muscles of both upper extremities strongly contracted.

We have now to pass in review twenty cases in which the details are more complete. In three of them only was paralysis absent. The first is due to M. Bayle; the patient suddenly became insensible, but retained the power of movement, for he quickly pulled away the upper and lower extremities when either of them were pinched. He died five days after the loss of consciousness, and on the third day from the attack he was seized with convulsions of the lower extremities and remarkable rigidity of the neck. Considerable hæmorrhage was found into the middle lobe of the cerebellum. The second is to be found in the thesis of M. Michelet, printed in 1827. An individual died two years after an attack of apoplexy; there had been blindness from amaurosis, but nothing is stated with regard to movement; the hæmorrhage was seated in one of the lateral lobes. The third case occurred to M. Droullain: there was no paralysis, but convulsions and rigidity of the neck, as in the case of M. Bayle; there was effusion of blood into one of the lateral lobes.

There remain seventeen cases in which the existence of paralysis was well made out; and of the others there are only two,—that of M. Bayle and that of M. Droullain,—with regard to which it can positively be said that paralysis did not exist. These seventeen cases resolve the first question in the affirmative, namely, whether hæmorrhage of the cerebellum produces paralysis. In all these cases the form of the paralysis was hemiplegia.

Let us now see what was the seat of the effusion. In one case only did it occur in the middle lobe. The observation is due to M. Ginaud, who published it in the Clinique des Hôpitaux, No. 90; there had been hemiplegia of the left side. In the sixteen other cases the hæmorrhage was situated in one of the lateral lobes; and we have to inquire whether the paralysis existed on the same or on the opposite side. In eleven the hemiplegia was opposite to the lesion. Of these eleven cases five are recorded in my Clinique, and others have been related by MM. Serres, Piorry, Rochoux, &c. In one of my cases, as well as in one recorded by M. Chambeyron, there was also hæmorrhage into the corresponding lobe of the brain; which reduces the eleven cases to nine in which the lesion was limited to the cerebellum.

We have formerly seen, with regard to the brain, that the paralysis was sometimes on the same side, sometimes on the side opposite to the organic lesion. Is it the same with respect to the cerebellum? To this question the last series of cases will afford us a rely.

There are two classes of cases to be considered, namely, where the cerebellum alone is affected, and where, while it is affected on one side, the cerebrum is affected on the other. 1st, May the cerebellum be affected alone, and on one side only? A case of this kind has been cited by M. Tarvenier: it is the only one which can be opposed to the crossing of the paralysis. An individual was attacked, in 1812, with apoplexy, characterized by complete paralysis of the left side, and by loss of speech, with preservation of the intellect. In 1820 he was seized with loss of power over the right side, and died in a state of coma, with stertor. In the left lobe of the cerebellum was found an old lesion, consisting of an apoplectic cyst, which corresponded to the *left* palsy of eight years' standing. At the same time, in the middle part of the left hemisphere of the brain, was found a recent effusion, which had caused the palsy of the limbs on the right side. At first sight this case appears complete; nevertheless, M. Tarvenier did not see the patient during his first attack, and took his account from the testimony of the man's wife. The case, therefore, standing alone as it does, is not of sufficient authority to warrant our drawing from it any conclu-

sion favourable to the possibility of direct paralysis from hæmorrhage of the cerebellum.

In the next division are to be placed those cases in which hæmorrhage has taken place simultaneously into one of the lateral lobes of the cerebellum, and into one of the hemispheres of the brain. One such instance is to be found in the thesis of M. Droullain; another was seen by M. Quesne at the Bicêtre; a third is to be found in the work of M. Rostan; and a fourth in the fifth volume of my Clinique. When hæmorrhage takes place into the lobes of the cerebellum alone, the paralysis is on the opposite side. What ought to happen when the cerebellum is affected on one side, and the cerebrum on the other? Clearly the limbs of both sides ought to be paralyzed. Yet, in the four cases above quoted, the power of motion remained entire on the side opposite to the lesion of the cerebellum,—the affection of the brain alone had any influence over the limbs; and the same effect also took place where there was lesion different from hæmorrhage existing simultaneously on the opposite sides of the brain and cerebellum—as for example, in atrophy. The general consequences which follow from these cases are too obvious to require that they should be pointed out.

Hæmorrhage of the spinal cord.—Paralysis may also occur when the effusion of blood takes place into the spinal cord. This kind of case is very simple. In the greater number of instances of hæmorrhage into the cord, double paralysis takes place, and the upper or lower extremities are affected according as the effusion occurs high up or lower down in the spine. Sometimes hemiplegia has been observed where hæmorrhage has taken place into the anterior cords of the spinal marrow; and such paralysis is always direct when only one cord is implicated.

Various forms of paralysis.—Other parts besides the limbs may be paralyzed in hæmorrhage of the nervous centres, and this particularly when the brain is the part affected; for with respect to other parts, the circumstances are not sufficiently ascertained. The muscles of the eye have been known, though very rarely, to be paralyzed; and as all its muscles are not affected at the same time, inasmuch as they do not all obey the same nerves, strabismus has been much less frequently seen in hæmorrhage of the brain than in various other affections of the same organ. The elevator of the upper eye-lid is sometimes paralyzed; and I have known this occurrence precede the hæmorrhage by fifteen days, without any other premonitory symptoms.

When the paralysis affects the muscles of the cheek, it is always on the same side as that of the limbs; the commissure of the lips is dragged to the opposite side by the muscles which are not paralyzed. The paralysis of the buccinator produces certain phenomena when the patients breathe with the mouth shut; the muscle becomes distended, and when the lips are separated the air escapes with a noise, constituting what is called the patient *smoking his pipe.* When he attempts to masticate, it is perceived that he cannot use the necessary muscles. There are also other effects resulting from paralysis of the cheeks, which, however, it is unnecessary to detail. As to the rest, although in the immense majority of cases the face be paralyzed on the same side as the limbs, there are, however, some very rare instances in which the opposite condition has been met with; we must then suppose that a double lesion exists.

Movements of the tongue.—These almost always undergo some modification. We may have complete hemiplegia, with paralysis of the face, without the tongue being the least affected; at other times the movements of the tongue are completely abolished, so that the patient is absolutely unable to put it out. Articulation is impossible; and this does not depend on want of the association of ideas necessary to the formation of language, but here it is the mechanical movementsof the tongue which are impeded. There is also another kind of dumbness, of which it is not within my present purpose to speak. Sometimes the paralysis of the tongue takes place only on one side; if the patient puts it out, it is to one side:—to which side? There is a variety in this respect. It is generally to the paralyzed side; however, in some rare cases the tongue is directed towards the side opposite to that of the paralyzed limbs: this probably depends on differences in the extent and seat of the palsy affecting the numerous muscles of the tongue. The movements of this organ often return before those of the limbs. The speech begins to be re established at the end of ten days, a fortnight, or a month; and it sometimes becomes completely or nearly restored, although the limbs recover none of their power. Most frequently the paralysis of the tongue is not so well marked as that of the limbs; but there are also some cases in which, after the attack, the limbs are scarcely feeble or numb, whilst the abolition of the action of the tongue is complete. We must also remark, that the movements of the tongue may be completely destroyed, although there be no loss of consciousness.

Muscles of the neck.—Paralysis of these is rare; when it does occur, it produces some change in the manner of carrying the head.

Muscles of respiration. — These also are very rarely affected with palsy, unless in cases of apoplexy which prove rapidly fatal; and the less degree of frequency of this paralysis is not at all astonishing in regard to muscles which are on the limits between the life of relation and vegetable life, and which serve as the transition between the muscles of organic and animal life.

The muscles of the larynx.—There are very few examples of this paralysis. M. Moulin, however, has related a case of it.

Muscles of the pharynx and œsophagus. — These muscles (which, however, are under the influence of nutritive life) are sometimes paralysed in very severe apoplexies. This paralysis, which impedes deglutition, leads but to an unfavourable prognosis. It is by this inability to swallow that the attack commences. M. Flandin has related the case of an individual, 28 years of years, who was seized all at once with loss of deglutition, without any other symptom. No suspicion was entertained of cerebral hæmorrhage, but this suddenly manifested itself will all its usual symptoms.

Muscles of the rectum.—These may be implicated in the paralysis; and from this results the difficulty of expelling the contents of the bowels.

Muscles of the bladder. — This form of palsy, which affects chiefly the fibres of the body of the viscus, is sufficently common; which circumstance ought to induce the attendant always to examine the bladder with the utmost care, in all cases of apoplexy, for the sensibility being diminished, the organ may actually burst from excessive distention.

It has been said that the muscular fibres of the stomach may be paralysed in hæmorrhage of the nervous centres; but the statement does not rest on any satisfactory evidence.

Cause of paralysis.—The paralysis, particularly that of the limbs, may remain till death, and thus last for a longer or a shorter time, according to the duration of the case. It may also disappear, but this only takes place slowly. The very rapid disappearance of paralysis is a strong reason for believing that it is not dependent upon hæmorrhage of the nervous centres. When life is prolonged during many years, the paralysis may continue still the same. Persons have been seen who have been attacked with apoplexy at the age of 40, and in whom, at 70, the palsy was as complete as at its onset. When paralysis lasts long, nutrition sometimes becomes impaired, and the limb wastes. This wasting commences, though certainly very rarely, within a month after the first attack, as I myself have seen. Instead of remaining thus persistent, the palsy may progressively diminish; but it is to be remarked that this form—this enduring palsy—is sometimes dependent upon a very slight lesion of the brain. Thus on the death of an individual who had suffered from paralysis for twenty years, only a white hard line was found in the brain, a simple cicatrix having interrupted the nervous continuity.

Lastly, the paralysis may disappear entirely. The hæmorrhagic nucleus in this case passes into a perfect cicatrix, across which the nervous influence admits of being propagated. When it disappears gradually, it does so in a certain manner. If, for example, we suppose the palsy to exist in the cheeks, lips, tongue, and limbs, it will cease first in the tongue, then in the face, then in the lips; and at a time when all the parts primarily affected have recovered their movements, the limbs may still be paralysed, unless in cases which constitute exceptions to the general rule. As to the rest, the palsy of the lower limbs yields sooner than that of the upper. The former, nevertheless, long retain some difficulty in their progression, but in the end every trace of paralysis by degrees may disappear.

In the cases where the power of motion appears to have become entirely natural, are we to suppose that there is always a complete disappearance of the lesion? Not so; for sometimes even then cysts, filled with serum, remain; but these, it is true, are exceptions.

LESIONS OF SENSIBILITY.

These lesions are various, and less constant than those which affect motion. They may manifest themselves first in the encephalon; secondly, in the skin; thirdly, in the organs of sense.

In the encephalon.—Frequently no change of sensation is observed in the brain before an apopleetic attack; but sometimes there is a weight about the head, headache, ringing in the ears, or giddiness, as premonitory of the hæmorrhage.

In the skin.—In most cases its sensibility is in no degree affected before the hæmorrhage; but various other disorders may be met with, such as the limbs easily becoming cold, numbness, formication, &c. These different affections may display themselves only in the skin of the fingers, or throughout the whole extent of the limbs, usually those of one side, viz. that which afterwards becomes paralysed.

Sometimes these phenomena shew themselves in the limbs of both sides at once; and this may be the result of different degrees of congestion. These lesions of the sensibility of the skin shew themselves sometimes only a few days, sometimes several years, before the attack. Thus in the fifth volume of my Clinique is the case of a woman who was attacked with apoplexy at the age of 52 years, in whom not the slightest disturbance of the motive powers had been observed, but who, from the age of 17, had experienced numbness and creeping in the limbs of the right side, which symptoms had at first been irregular and at long intervals, as well as confined to the arm, but which afterwards became constant, and extended to both limbs.

Thus previous to the attack, before the moment at which the effusion occurs, various disorders of the sensibility may take place, so that it is occasionally possible for us to predict on which side the hæmorrhage will supervene, by the side of the body where the premonitory phenomena of the sensibility shew themselves. Let me remark, however, that in general apoplexy is not preceded by any disturbance of this function.

When paralysis has occurred, the sensibility of the affected side is diminished or abolished; and in general, when the disease takes a favourable course, the lesions of sensation disappear before those of motion.

The mucous membranes may participate in the abolition of sensibility; thus in some apoplectic cases the conjunctiva is insensible when touched with the finger, which is in keeping with the same defect in other organs, and depends upon the alteration of the fifth pair of nerves.

Organs of sense.—Sight is sometimes, but not always, disturbed. We see individuals struck down with apoplexy, and affected with paralysis and loss of sensation, where, nevertheless, consciousness and vision remain. Different sensations resulting from disturbance of this function are experienced by patients, who describe them in different ways; some say that they have motes before the eyes; others that they see the light as through a cloud, just as on the onset of cataract,—yet here the crystalline is clear; others see various colours. Sometimes those who at a later period are attacked with apoplexy have the sight modified for a longer or shorter time before the attack, in such a manner that all objects appear double, a symptom which is sometimes transient, being present one day and not another; in other cases it is persistent. In some cases the loss of sight is nearly complete; but such cases are very rare. When the sight is lost, this may take place on one side or on both; and this blindness coincides with the loss of numerous other senses. In various works cases are to be found in which the sight is said to have been preternaturally acute for some time before the attack.

[To be continued.]

ADEQUATE REMUNERATION OF PRACTITIONERS

FOR PAUPER MEDICAL ATTENDANCE.

To the Editor of the Medical Gazette.

Sir,

Having been lately requested to sign a protest of the general practitioners in medicine of this part of the country, against the misrepresentations of the Poor-Law Commissioners, which, although in no way interested, except as the advocate of justice and humanity, I had great pleasure in doing; and having for many months past listened to endless discussions, and read an infinity of remonstrances, and letters, and complaints, on the subject, I still think that the main points and strength of the case have been overlooked; and therefore, should you think this letter of an impartial bystander worth publication, I beg you will give it a place in the first spare corner of the Medical Gazette.

Every one will admit that our Government must have been actuated by the laudable desire of insuring proper medical attendance to the sick poor of the country; and it remains to be seen whether their agents, the Poor-Law Commissioners, have adopted the proper steps for effecting that national object, or whether they have not, on the contrary, sought to slur over the calls of true humanity, and, as I shall presently shew, by practising on the fears of the established medical officer, driven bargains, and on degrading terms exacted an amount of duty from him, which never can be rendered with the effect sought to be attained, because in their rage for union and centralization, they have in many instances removed the sick poor as effectually beyond his eye, and out of his reach, as if the object had been to deny them all medical assistance whatever.

It has ever been easy to be charitable at the expense of others; and the game has too often been played of seeking popular applause to the prejudice of justice. When the Poor-Law Commissioners, therefore,

claimed credit for economical reform, by advertising for the lowest tenders, and calling up the inexperienced needy adventurer from the schools, in want of a place, to underbid the established practitioner who had long been in charge, they handed over the sick poor to serve the purpose of the former's unprincipled speculation, or held him up *in terrorem* over the latter, with the view of imposing conditions upon him which he never could execute in fairness either to the unfortunate paupers or himself; but to which, in order to preserve the practice on which he subsisted, he found himself obliged to submit.

This surely was intimidation, and not justice; far less could it come under the denomination either of charity or humanity. And as it must be the aim of every parental government to protect all classes of its subjects, the numerous medical practitioners throughout the land have a right to invoke its protecting shield against their present oppressors; and this can be extended to them effectually only in the way of a national enactment, providing medical attendance in every parish for all the paupers, whether sick or well, in the list, on equitable terms, at so much annual cost per head; and then the Commissioners, by selecting and appointing the best, instead of advertising for the worst, may exercise, and under proper regulation enforce, that humanity to which they were so falsely laying claim.

As a contract, take it in what way you will, always implies eventual gain to the contractor, every system of tender and underbidding must be bad; and in the long run the sick poor must be the only sufferers.

The system I advocate, were it fairly entertained by the legislature, would be national, humane, and just to all parties. It has for ages, under certain modifications, been practised in the army and navy; it was, as I have witnessed, executed with the best effect amongst all the communities of negroes throughout the West Indies; and I can conceive no good reason why, *mutatis mutandis*, it may not be brought into operation amongst the pauper population of Great Britain. One mighty advantage would be the simplification of accounts, of regulation, and of duty. All would be comprehended, without confusion or dispute, under one principle of action; and if the reciprocity of compensation and duty be justly poised, the sick poor would be duly cared for, and the medical attendant not degradingly, because not unjustly, rewarded.

Any other plan than this must be fraudulent, as laying claim to charity, and that too without effecting the object, at the expense of the medical profession; while it cannot fail to involve the members of this last in perpetual contest with the Poor-Law authorities; the one seeking to impose, the other to avoid, impossible duties, and all to the prejudice of the poor. This would be clear and intelligible to every one; and should it appear so to the profession, I hope they will arise as one man to seek the protection which its enactment would afford. I do not here enter into details to prove the foregoing, or to shew that the best established practitioner of every parish, from his knowledge of the pauper's character, and the responsibility for his own, must ever be the fittest in the first instance, and should never be employed out of its bounds, or, at least, beyond his beat; for the sick poor require to be protected against neglect, as much as their doctor against oppression; but I am ready to do so should my statements be disputed.

Having of late avoided to converse, and ceased to read, upon this tiresome subject (for nothing is so tiresome as the reiterated language of unredressed grievance), I really cannot tell whether the above proposal may not already have been laid before the public through some other channel: if it has, this letter will be superfluous; but if otherwise, its publication in the Medical Gazette may probably in some degree serve the cause of the profession.—I have the honour to remain, sir,

Your most obedient servant,

WM. FERGUSSON, M.D.
Inspector-General of Hospitals, H.P.

Windsor, Jan. 20, 1836.

THE MEADE-AND-WAKLEY MEETING OF MEDICAL STUDENTS.

CONDUCT OF THE PARTIES *.

To the Editor of the Medical Gazette.

SIR,

PERMIT me, through the medium of your journal, to call the attention of the profession, and of the public generally, to some peculiarities that marked the proceedings of the *soi-disant* meeting of medical students, held on Monday evening, in the Strand.

Allured by curiosity, as indeed were a great number of individuals present, knowing little or nothing of the merits or demerits of the questions to be brought under discussion, and having been subsequently led to make some inquiries as to the truth of some of the statements then and there put forth, I think it due to the

* The name and address of the writer have been sent to us.—E. G.

profession, and to the public generally, to offer a few passing remarks, in which I propose to confine myself to what would be called the business of the meeting.

The students were invited to the meeting without their being told more than that the proceedings would be of a nature deeply affecting their interests. We were soon enlightened as to the objects the conveners had in view. A medical student had gone up to Apothecaries' Hall, for examination; he was pronounced incompetent to undertake the duties of his profession, and sent back to complete his studies. Whether the pupil had been careless, or his teacher had failed in discharging his duty, did not transpire; but judge of my surprise to find the said teacher of the rejected student occupying the chair on the occasion. The *onus* of the young man's rejection must rest somewhere. Assuming the Board of Examiners to be impartial—and it was the interest of the board to be lenient rather than severe, as unsuccessful students, it appears, do not pay the fees — assuming, then, the Board to be impartial, the fault must be either with the pupil or the teacher, and both must doubtless feel considerable soreness at the rejection. Was it proper, then, nay, was it decent, that a party concerned should preside — that the defendant should be the judge? But it was so; and he exercised the prerogative accordingly. Could a man so delicately situated be expected to bring an unbiassed mind to the discussion, or treat with fairness those whose conduct he attacked, whose motives he impugned, and, in animadverting upon whom, he forgot that all the parties concerned were, or ought to be, gentlemen. He said this rejection was the second that occurred to his pupils; and although it did not appear that any other teacher had to complain of similar treatment, he considered the rejections a proof of personal pique on the part of the Examiners. This was a miserable subterfuge; for he did not even condescend to inform the students that the gentlemen whom he loaded with coarse vituperations even knew him personally. How important would it have been to have shewn the grounds on which he was personally unpopular with the Examiners!

But let me ask, where did the chairman get his information as to the questions proposed, and the answers given? Could it be any thing but *ex parte*; any thing but the *ipse dixit* of his pupil, embellished and corrected by himself. Well; here is a young man sent up for examination, and failing to answer satisfactorily the queries proposed, he is remanded. Either the Examiner or himself is in error. Will he be likely to retire from the board and take the blame upon himself? Will his teacher, or *grinder*, whose business it is to furbish up students of limited information, be likely to acknowledge himself in error, or will he not rather be inclined to say practically, "I am superior teacher, you are a proficient, and the Board of Examiners must be in the wrong?" So it is; the student retires chagrined and mortified: not willing to confess his stupidity or carelessness, he tells his grinder how cruelly he was overhauled, and the teacher, not willing to advertise his own incompetency as a judge in the proficiency of his pupils, says in effect, "aye, you are a very clever fellow; and as for the Examiners, they are tyrannical, despotic, corrupt," and what ever else he can, in the abundance of his *liberalism*, think of. This young man's partial statements (it is next to impossible they can be otherwise) are taken to his teacher, and by the latter, whose professional reputation is involved, to a public meeting, and there the man is placed in the chair to "play his own fiddle;" his calumnies are applauded, his base insinuations pronounced capital, and his jaundiced view of a case he has made his own, received as gospel. Really the stretch of credulity here exhibited seems almost incredible, and yet it is no fiction. It is difficult to say which is most admirable, the modesty of the man who could obtrude himself at all (much less as chairman) upon the meeting, under such circumstances, or the shallowness and trickery of those who could tolerate such an outrage of all decency.

Next in order, my attention was called to the insulting exhortations of the chairman to his audience, to behave with propriety. For myself, I felt insulted. What! is it to be credited that medical students know no better how to demean themselves, and at a public meeting, too, at which matters affecting their own interests are to be discussed, than so many coal-heavers, that they should be cautioned again and again not to be so uproarious? Surely the chairman must have a sorry opinion of the medical students present; but, as was subsequently proved, his exhortations, so frequently reiterated, were by no means unnecessary. On taking a survey of the motley assembly, I was more than convinced that the young gentlemen present would need a pretty severe examination, and that many, unless in future they betake themselves to study, and leave off raking, would "when weighed in the balance be found wanting." The carelessness of many, the obstreperousness of others, and the positive gross ill conduct of not a few, gave one a most painful and humiliating picture of the march-of-intellect gentlemen of the medical schools.

Any thing like being heard, if opposed to the medical radicals, was out of the question. "Bah," "shut your shop," "show him up," "lift him upon the table," "don't make a fool of yourself," "let's have Wakley, we want to hear him, and go to half play," with an admixture of howls, groans, and cat-calls, distinguished the proceedings of the evening, and proved that the seemingly impertinent advice of the chairman was not out of season.

The mover of the first resolution came ready charged with a mighty grandiloquent speech, but unfortunately he lost the *thread* of his discourse just when boiling over with indignation. "That, that, that," said he, "I don't know what to call it; that monstrosity — that monopoly — that sink of infamy, oppression, and tyranny, shall be as execrable in its death as it has been odious in its life." Having gathered himself up at the *terminus,* and discharged this elegant piece of eloquence, the pop-gun disappeared, and was pronounced very grand. The orator in question proved, "quite entirely" to the satisfaction of the meeting, that medical students of the present day are vastly superior to medical practitioners of twenty, thirty, or forty years' experience.

The trick to cover "the nakedness of the land," by authorizing the chairman to sign a petition to the Commons, in be half of the meeting, succeeded well. An amendment was moved, that each student sign it; but that would have proved too much. "Don't humbug us with signing," said one; "I'm not going to be *hashed* up with such a concern," said another; and if the amendment had been carried, verily there would not have been fifty signatures affixed to the petition, grinders and all.

It was broadly attested that questions were put to students by the Court of Examiners, the only tendency of which was to puzzle and embarrass them; and that it was impossible to say, whatever might be a man's attainments, whether he would pass or not. How does this square with the announcements put forth respecting the establishments of the different teachers? One gentleman says "he holds himself responsible for the success of his pupils," and even the chairman himself modestly tells the public that "the unequalled success which has attended the examination of his (the chairman's) pupils at the above institutions (the College and Apothecaries' Hall), is the best criterion of the efficiency of his mode of instruction." Is this a puff, or is it true?—and if true, the charges of tyranny, corruption, and private pique, with which his speech of Monday was beautifully interlarded, must be something which I care not to name. And then, can it be believed that the medical profession has submitted to such a state of things as the diseased imaginations of the reforming orators depicted on Monday evening, for full twenty years? Impossible.

Last, though not least, a word or two of the lion of the evening, who was evidently kept back lest the young men should have scampered off before the business was done, leaving the self-elected committee-men "alone in their glory."

Mr. Wakley set out by assuring them, that if ever he spent a happy evening it was *that* evening. Perhaps so; but was he ever happy a whole evening? Can a man of his temperament be happy? But letting that pass, what was there to make him happy? Much coarse vituperation—many gross charges made against gentlemen who were absent, and who had no business there, not being medical students; which charges were unsupported by a tittle of evidence. This made the man happy: to be sure, there were the howling and hissing, and clamouring down of all who dared to oppose the chairman's views; added to which, the young gentlemen had begun to burn, not "their midnight oil," so pathetically alluded to by the speaker, but their cigars! With all this, Mr. Wakley was happy, and thereupon began his oration. First, he bepraised himself and his twelve years' exertions, having, as he said, "persevered through much calumny and falsehood," which nobody will deny, and really, had nature blessed him with pathos, he would have had us believe that he had sacrificed great things for the sake of the profession. What insufferable cant is all this! He knows very well that the Lancet pays better than pills and boluses; hence the secret of his services.

Next he began to bespatter the youngsters in a style somewhat after the fashion of Lord Brougham's northern speeches, in which he bedaubed the King. Any thing so fulsome as these eulogiums upon medical students I never heard, and it was easy to see that the man was not in earnest. He made them the very patterns of care, perseverence, toil, self-denial, and martyrdom! Such an announcement from the Lancet hero contrasted strangely with the rakish faces, the gossip, and the smoking cigars, of many around me. Mr. Wakley subsequently "went upon another tack," and there he was at home and *happy!* I cannot follow him through his misrepresentations and low abuse, but I could not but be struck with the effect of one observation. All along it had been assumed that public examinations would set every thing to rights. In unison with this opinion, Mr. Wakley said, "get your new university, gentlemen—your public

examinations, and then let them put such questions to you, and one simultaneous *hiss* from 1500 voices will teach them better." "Hark ye, Harry," exclaimed one wag; "fifteen hundred spectators! that's worse and worse; better be as we are, than have so many folks to jeer us; that's no go, Harry." There seemed to be a great number of the same opinion.

Seriously, sir, what do these gentlemen want? The discontent is not with the students so much as with the grinders. Do the latter covet to be Examiners, or do they not rather want to be both teachers and examiners? Let matters come to this, and they would soon earn their thirty guineas—soon polish up their students.

I am, sir,
Your most obedient servant,
J. B.

London, Jan. 20, 1836.

ST. THOMAS'S HOSPITAL.

MEETING OF STUDENTS.

At a public meeting of the students of St. Thomas's Hospital, held on the 26th January, William Wegg, Esq., in the chair, the following resolutions were proposed, seconded, and carried unanimously:—

1. That the Court of Examiners of Apothecaries' Hall, from the period it was first instituted, and invested with the powers it now possesses, has by the gradual and progressive development of its rules and regulations, thereby exacting from students a certain quantity of useful and practical information, contributed much to the advancement of the medical profession, and, as a necessary consequence, been attended with great good to the public at large.

2. That it has not yet been proved that the Court of Examiners of the Apothecaries' Company have in any case evinced partiality towards, or unfairly rejected, any candidate for the license.

3. That we disclaim all participation in the proceedings of the meeting of medical students, held at the Crown and Anchor Tavern, on Monday, January 18, and in many of the sentiments there expressed; but more especially in the unjust and unwarrantable abuse directed against the members of the Society of Apothecaries.

4. That this meeting regrets there does not exist a second examination, and that second examination a public one, to which any rejected candidate might appeal, as this would at once silence the murmurs of incompetency, and destroy the possibility of private injustice. That this meeting also strongly disapproves the principle of self-election and irresponsibility.

(Signed) W. Wegg, Chairman,
Chas. Edw. Blair, Secretary.

NEW PHARMACOPŒIA.

We are happy to be able to state that there is at length a prospect of the new Pharmacopœia appearing without further delay. We have been informed that the manuscript is completed, and that a portion of it is already printed. All the new remedies of established character have been introduced, and the nomenclature adapted to the discoveries of modern chemistry.

PROFESSORSHIP OF MATERIA MEDICA, KING'S COLLEGE.

Dr. Paris, so recently elected to the above chair, unexpectedly resigned it again about a fortnight ago. Dr. Webster, who has been lecturing *pro tempore*, was requested to give the Spring course, but declined to do so unless the professorship was guaranteed to him, which arrangement not being acceded to, he retired. An application was then made to Dr. Gregory, by whom the ensuing course of lectures is to be given, the chair being left open to the candidate who shall be deemed most eligible.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XIX.

I PROCEED now to the examination of those medicinal agents obtained by the decomposition of animal substances, and first of

HYDROCYANIC ACID.

History.—At the commencement of the 18th century the substance called *Prussian blue* was accidentally discovered, and various conjectures were soon offered regarding its nature. In 1746, Dr. Brown Langrish employed laurel-water medicinally. In 1752, Macquer announced that Prussian blue was a compound of oxide of iron, and some colouring principle which he could not isolate; and in 1772, Guyton Morveau concluded this principle was of an acid nature. Scheele, in 1782, removed some of the mystery connected with Prussian blue, by obtaining *hydrous prussic acid* from it, which in five years afterwards Berthollet ascertained to be a compound of carbon, nitrogen, and hydrogen. In 1800, and 1802, Bohn and Schrader discovered prussic acid in laurel-water. Borda, Brugnatelli, and Rasori, first employed the acid in medicine, from 1801 to 1806. In 1815, Gay-Lussac obtained the acid in its pure *anhydrous* state, and explained its composition.

Synonymes and Etymology.—It has been denominated prussic *(acidum borussicum)*, zootic, and hydrocyanic acid: the first name indicates the substance (Prussian blue) from which it was obtained, the second refers to its animal origin, and the third indicates its constituents, hydrogen and cyanogen (so called from κύανος, blue; and γενναω, to produce; because it is one of the constituents of Prussian blue).

Native state.—Hydrocyanic acid is never found native in the inorganic kingdom, (the mineral called, by Haüy, *fer azuré*, by others *native Prussian blue*, is a subsesqui-phosphate of iron); it is, therefore, invariably an organic product. It is readily obtained both from many vegetable and animal substances, but it is not easy to say whether it exists in them already formed, or is the result of the process by which it is procured. Two families of the vegetable division of the organic kingdom have long been remarkable for containing it,—namely, *Amygdaleæ*, and *Pomaceæ*. Thus it has been said to exist in bitter almonds, in apple-pips, in the kernels of the peach, apricot, cherry, plum, damson, &c.; in the flowers of the peach, sloe, and mountain ash; in the leaves of the peach, cherry laurel, and bird cherry; in the bark of the latter, and in the bark and root of the mountain ash. These, however, are not the only vegetables in which the existence of hydrocyanic acid has been asserted: in *Rhamneæ* it is said to have been found in the bark of one species, namely, the rhamnus frangula; and lastly in *Gramineæ*; for we are told by some that the ergot of rye contains it, the truth of which assertion, however, has been denied by others. That from most of the substances now mentioned hydrocyanic acid may be readily obtained, is well known, but in some of the instances it appears the acid does not exist ready formed in the vegetable, but is a product of the process by which it is obtained. This has been particularly observed in reference to the bitter almond, and has been inferred with respect to several others. At present, however, I can only just allude to the circumstance, and hereafter, when speaking of vegetable substances, I shall more particularly explain the grounds for this belief.

Hydrocyanic acid does not appear to be

a natural product of animals: yet Prussian blue has been found in the urine, in the menstrual fluid, and in the sweat, and as this substance contains one of the ingredient of hydrocyanic acid (cyanogen), it is not improbable that under particular circumstances this acid might be formed. We are told that when cheese is exposed to the action of water and the sun, it disengages an ammoniacal odour, and in this state, if treated by alcohol, yields traces of hydrocyanic acid.

Preparation.—It is not necessary, I conceive, in pharmacological lectures, to enter into a detailed account of all the processes by which hydrocyanic acid has or may be procured: it will be sufficient to point out those which are considered the best. Directly or indirectly the acid of commerce is always obtained from the ferrocyanuret of potassium; and I shall, therefore, briefly allude to the mode of procuring this substance.

1. *Production of Ferrocyanuret of Potassium.*—The usual method of obtaining this salt is as follows:—Animal matters (such as blood, hoofs, horns, shavings of leather, &c.) are calcined with pearlash in an egg-shaped iron pot, being well stirred all the time with a flat iron paddle. When the fœtid vapours have ceased, the pasty mass is thrown into water, and the clear solution evaporated. To purify the crystals thus obtained, they are re-dissolved in water, and the solution allowed to cool very slowly. The *theory* of the process is not completely understood: the following will serve to explain the production of the salt:—The heat decomposes the animal matters, part of the carbon and nitrogen of which are attracted by the potassium of the pearlash, and thus cyanuret of potassium is produced. A cyanuret of iron is also formed by some of the carbon and nitrogen uniting with the iron of the pot and of the stirrer. By the union of the cyanuret of potassium with the cyanuret of iron, the ferrocyanuret of potassium is formed.

Mr. Lowe has taken out a patent for procuring pure Prussian blue from the ammoniacal liquor of gas works, in which is found hydrocyanate of ammonia. From the lime-water with which the gas has been purified, and which was formerly allowed to run to waste into the river Thames, we may also procure Prussian blue, but mixed with sulphate of lime. The process, in either case, is to add sulphate of iron to the liquor, and then supersaturate with sulphuric acid: Prussian blue precipitates. As the ferrocyanuret of potassium may be readily obtained by boiling Prussian blue with potash, we may expect ere long to derive all our ferrocyanuret of potassium in this way, and at a cheaper rate.

Composition of Ferrocyanuret of Potassium.

Elementary.		Secondary.	
6 Carbon	36	2 Cyanuret potassium	132
3 Nitrogen	42	1 Cyanuret iron	54
2 Potassium	80	3 Water	27
1 Iron	28	1 Crystallized ferrocyanuret	213
1 Anhydrous ferrocyanuret	186		
3 Water	27		
1 Crystallized ferrocyanuret	213		

The formula for this salt in the anhydrous state, is this:—2 (K Cy) + Fe Cy.

2. *Production of hydrocyanic acid from ferrocyanuret of potassium.*—*Giese's process:*—Dissolve 5 drachms of pulverized ferrocyanuret of potassium in 20 drachms of water; then add 14½ drachms of dilute sulphuric acid, (composed of 10 drachms of water, and 4½ drachms of acid) and distil until the materials become thick or pasty. About 30 drachms of distilled acid are obtained, (or if the quantity procured be less than this, water is to be added to make up the amount) which contain about 3·3 per cent. of real or anhydrous hydrocyanic acid. The process may be performed in a tubulated retort and receiver, employing an adopter; or a large matrass may be used in the place of the retort. For the above quantities I have employed two Florence flasks, one for the receiver, the other for the distilling vessel, connecting them by a glass tube curved twice at right angles. The receiver must be kept very cool, ice or snow being used if they can be procured; and the heat employed to distil the acid should be very moderate. The distilled liquor usually contains a little sulphuric acid, and by standing deposits a small portion of Prussian blue. By a second distillation both these may be readily separated. This process is by far the cheapest, and yields a very constant and permanent product. **Medicinal acid**

may be sold at one penny per ounce, yielding more than a half-penny profit to the manufacturer. The small portion of sulphuric acid which distils over is supposed to contribute to its preservation.

When the dilute sulphuric acid is added to the solution of ferrocyanuret of potassium, water is decomposed: the hydrogen of which, uniting with some cyanogen of the ferrocyanuret, constitutes hydrocyanic acid; while the oxygen of the water, with some of the potassium, generates potash, which, with the sulphuric acid, forms a sulphate of potash; and at the same time a new insoluble salt is formed, composed of cyanogen, iron, and potassium.

Thus far the account which I have given of the decomposition is undoubtedly correct; but if we investigate the phenomena a little more minutely, we are involved in doubt and uncertainty. Gay-Lussac states this new salt is white, and that it consists 9 atoms cyanogen, 7 atoms iron, and 2 atoms potassium. But it appears to me he has deduced the composition from theoretical rather than experimental considerations, and consequently his results are not to be relied on. Mr. Everett, on the other hand, tells us the new salt is of a light lemon yellow colour, and that its composition is 3 atoms cyanogen, 2 atoms iron, and 1 atom potassium: these proportions he has determined from numerous carefully conducted experiments, so that I have no hesitation in adopting his results, except in regard to the colour of the salt. By the following contrivance, I managed to act on the solution of ferrocyanuret of potassium by the dilute acid to the perfect exclusion of every particle of air, and found the salt to be *white*, as described by Gay-Lussac; but I also observed that the application of heat gave rise to the formation of a little Prussian blue. A retort was filled with the solution of the ferrocyanuret, and a curved tube filled with distilled water introduced into the retort (while the beak was under water) as far as the bulb: the dilute acid was then poured down the long leg of the tube (which was a foot above the surface of the water). On the application of heat, a copious *white* precipitate took place; and I observed that to whatever part of the bulb the heat was applied, streaks of Prussian blue were immediately apparent. No yellow or green colour was observed.

The following will explain the results, according to Mr. Everett:—

Reagents.

2 Atoms crystallized ferrocyanuret of potassium	426
6 Atoms anhydrous sulphuric acid	240
	666

Results.

3 Atoms hydrocyanic acid		81
3 Atoms bisulphate potash		384
3 Atoms water		27
New salt (*bi-ferrocyanuret of potassium*)	1 atom cyanuret potassium	66
	2 atoms cyanuret iron	108
		666

The symbolic representation of these results is as follows:—

Reagents.	Results.
2 (2KCy + Fe Cy)	3 (H + Cy)
6 $\ddot{S}$	3 ($\dot{K}$ + 2$\dddot{S}$)
	3 $\dot{H}$
	KCy + 2 (Fe Cy).

The salt which I have here called *bi-ferrocyanuret of potassium* by exposure to air generates Prussian blue.

Production of hydrocyanic acid from bi-cyanuret of mercury.—At Apothecaries' Hall, hydrocyanic acid is prepared from one part bi-cyanuret of mercury, one part hydrochloric acid (sp. gr. 1·15), and six parts water. The mixture is to be distilled until six parts pass over. The acid thus obtained has a sp. gr. of 0·995; and Mr. Hennell tells me the standard strength of it is such, that two fluid drachms dissolve 14 grains of the red oxide of mercury. The per centage strength, therefore, would be about 2·9.

The *theory* of the process is very simple: the chlorine of the hydrochloric acid forms corrosive sublimate with the mercury of the bi-cyanuret; while the hydrogen with the cyanogen produces hydrocyanic acid.

The symbolic representation of the decomposition is as follows:—

Reagents.	Results.
Hg + 2 Cy	2 (H + Cy)
2 (H + Chl.)	2 Hg + Chl.

This process offers no advantages over the one before mentioned, while it has the objection of being more troublesome and expensive; since we have to procure, in the first instance, bi-cyanuret of mercury. This salt is sometimes procured by boiling in water Prussian blue with the nitric oxide of mercury: but it is more cheaply produced by saturating hydrocyanic acid (obtained by Giese's process) with the nitric oxide of mercury, while the resulting salt is much purer and whiter.

Production of hydrocyanic acid from cyanuret of silver. — This is the process proposed by Mr. Everett, and I think is calculated to yield an acid of uniform strength. "Into a phial capable of holding rather more than one fluid ounce, put forty grains of the cyanuret; add seven fluid drachms twenty minims of water, and forty minims of dilute muriatic acid (sp. gr. 1·129); cork closely, shake

several times for the first quarter of an hour, set aside to allow the chloride of silver to fall, decant the clear liquid into another bottle to be preserved for use. Every fluid drachm will contain one grain of real hydrocyanic acid."

The *theory* of the process is this:—The chlorine of the muriatic acid forms, with the silver of the cyanuret, chloride of silver, while the hydrogen, with the disengaged cyanogen, generates hydrocyanic acid. Cyanuret of silver is procured by adding hydrocyanic acid to nitrate of silver: water (holding in solution nitric acid) and cyanuret of silver are the results. The symbolic representation of the decomposition is as follows:—

Re-agents.	Results.
Ag + Cy	H + Cy
H + Chl.	Ag + Chl.

The advantage of this process is its yielding a product of uniform strength; its objections, the trouble and expense. Mr. Everett says that practitioners could obtain an ounce of acid by this process for one shilling, while the manufacturer of the cyanuret could obtain 50 per cent. profit by it. It appears to me, that if the strength of medicinal hydrocyanic acid were fixed, this process would be quite unnecessary; since manufacturers can readily ascertain the strength of their product, and modify it, to meet the directions of the College, with very little trouble.

Production of hydrocyanic acid from cyanuret of potassium. — This process was originally proposed by Dr. Clark, and has been adopted by Mr. Laming. The formula of the latter is the following, 22 grains of cyanuret of potassium, 50 grains of crystallized tartaric acid, 6 fluid drachms of water, and rectified spirit of wine 3 fluid drachms. One fluid drachm of the decanted clear liquor contains 1 grain of pure hydrocyanic acid.

The *theory* of this process is as follows: part of the water is decomposed, the oxygen of which unites with the potassium, forming potash, which combines with the tartaric acid to form bitartrate of potash; the greater part of which precipitates: the hydrogen of the water, with cyanogen, forms hydrocyanic acid.

The symbolic representation of this is as follows:—

Re-agents.	Results.
K + Cy	H + Cy
$\dot{H}$	$\dot{K} + 2\,\bar{T}$
$2\,\bar{T}$	

The professed advantage of this process is the uniformity of the strength of the acid. In this respect, however, I think it inferior to Mr. Everett's, since the cyanuret of potassium is deliquescent and liable to spontaneous decomposition, proved by its hydrocyanic odour. Another objection is the trouble and expense of procuring pure cyanuret of potassium. It is but justice to Mr. Laming to state that his cyanuret of potassium is very pure, and is sold at a moderate price.

Strength of medicinal hydrocyanic acid.—It is to be hoped that the new Pharmacopœia now in preparation will give a fixed standard of strength of this acid. That this is much needed must be obvious to every one: I cannot bring forward any accidents which have happened for want of it in this country, yet danger is to be apprehended from the varying strength of the acid found in the shops. The following dreadful occurrence at one of the Parisian hospitals in June, 1828, will show the importance of what I have now stated:—In the shops of Paris a syrup of hydrocyanic acid is kept, composed, according to the formula of Magendie, of one part of medicinal acid to 129 parts of syrup; while in the Hôpital Bicêtre the syrup was prepared according to the codex—that is, one part of an acid (called Scheele's) to nine of syrup. A physician to the hospital, who had been accustomed to prescribe the former in private practice, ordered his usual dose to be given to seven hospital patients, not knowing that the hospital preparation was of a different strength. Half an ounce was accordingly administered to them successively: the result was fatal to the whole; all were dead within forty-five minutes.

Two methods have been proposed for determining the strength of the acid,—one by observing how much of the red oxide of mercury is dissolved by it, and dividing the quantity by 4. Thus: suppose 100 grains of dilute acid dissolve 10 grains of the oxide, the quantity of real acid in the 100 grains would be $\frac{10}{4}=2{\cdot}5$. The other, and best method, is by precipitating the acid by nitrate of silver. The mode of proceeding is as follows:—weigh carefully in a small phial 100 grains of the hydrocyanic acid, to be examined; to this add a solution of nitrate of silver, until precipitation no longer takes place. There can be no harm in using an excess of the nitrate, but a fallacy if a deficiency be allowed. Collect the precipitated white cyanuret of silver, and dry it. When completely dry, weigh it: every 100 grains are equal to 20·9 of real hydrocyanic acid. For example: suppose the dried cyanuret weigh $13\frac{1}{2}$ grains, by the Rule of Three you easily ascertain the quantity of real acid in the 100 grains of liquid acid examined; for every $131\frac{39}{100}$ grains of cyanuret have been formed from 27·39 parts of hydrocyanic acid,—therefore, you state the question as follows:—

$$\text{If } 134{\cdot}39 : 27{\cdot}39 :: 13{\cdot}5$$

By working this, you will find the result to be 2·007. Hence you say that the 100 grains of liquid acid were composed of—

Real acid	2·007
Water	97·993
	100·000

It must be recollected, that if muriatic acid be present, the result will be fallacious, since chloride, as well as cyanuret of silver, would be formed. The proper mode of proceeding, then, would be to distil the suspected acid from marble (which retains the muriatic acid), collect the product, and test its strength as above mentioned.

In the Dublin Journal for November, 1835, Dr. Geoghegan has proposed, for the detection of foreign acids in medicinal hydrocyanic acid, a salt which we may denominate the *Hydrargyro-cyanuret of the Iodide of Potassium.* If a concentrated solution of the cyanuret of mercury be mixed with a solution of iodide of potassium, a precipitate takes place consisting of white or pearly crystalline plates; these are the crystals of the salt in question. Now, if you take a few of these upon a rod and place them in a glass, adding the hydrocyanic acid you are about to examine, no change is observed if the acid be pure, but if a drop of muriatic, sulphuric, or any other acid, be present, a red (or a yellow, becoming red) precipitate of the bin-iodide of mercury is observed. I have tried this test two or three times, and it appeared to me to answer the purpose very well.

The medicinal hydrocyanic acid sold in the shops as being of Scheele's strength, varies considerably. Mr. Everett states that samples from Allen, Hanbury, and Co. yielded 5·8 per cent.; from Apothecaries' Hall, at different times, from 2·1 to 2·6 per cent.; and from several sources, only 1·4 per cent. You will naturally ask, what ought to be the strength? It is difficult to answer this question, since Scheele's process does not give a uniform result. The standard strength at Apothecaries' Hall, according to the statement of Mr. Hennell, already referred to, is about 2·9. Magendie states, that the *pharmaciens* of Paris imitate it by mixing 40 parts of water with 1 of pure acid, which give the per centage strength 2·5. As prepared by the Dublin College, its strength is about 1·6. That obtained by Giese's process should be 3·3 per cent.; Mr. Laming's acid is 1·66.

Preservation of the medicinal acid.—Medicinal hydrocyanic acid, free from all impurities, soon decomposes; but when mixed with a little sulphuric, or even muriatic acid, it is a much more permanent compound. It is supposed that on this account the acid prepared by Giese's process will keep unaltered for years, owing to the presence of some sulphuric acid. Dr. Christison has had some unchanged for two years and a half, though exposed to day-light. Mr. Barry adds a little muriatic acid to all his medicinal acid, to preserve it.

Hydrocyanic acid should be kept in a well-stoppered bottle, excluded from light; for both air and light hasten its decomposition, though they are not essentially necessary to it. Sometimes the decomposition is marked by a change of colour, but at other times the liquid remains perfectly colourless.

Properties and composition of anhydrous hydrocyanic acid. — Anhydrous hydrocyanic acid is a solid at 0° F. (some state at 5° F.), having then the appearance of crystallized nitrate of ammonia: it readily melts, forming a limpid, colourless liquid, having an intense and peculiar odour; its taste is at first cool, then hot; at 45° its sp. gr. is 0·7058, and at $64\frac{1}{2}$ is 0·6969. In this state it is exceedingly volatile: a drop placed on glass freezes by its own evaporation. It unites with water and alcohol in every proportion. At 79° or 80° F. it boils, forming hydrocyanic acid vapour, which is combustible; and when mixed with oxygen, explodes, yielding carbonic acid, nitrogen, and water. This, therefore, is one method of analyzing it.

Before Combustion.

H Cy *vap.* =27	O =16	O =16	O =8

After Combustion.

$\ddot{C}$ =22	$\ddot{C}$ =22	N =14	& H =9

Inferences.

H Cy *vap.* =27	contains	C *vap.* =6	C *vap.* =6	N =14	H =1	or	Cy =26	H =1

You observe that 2 volumes of hydrocyanic acid vapour, mixed with $2\frac{1}{2}$ volumes of oxygen gas, and exploded by the electric spark, yield 2 volumes carbonic acid, 1 volume nitrogen, and 1 atom of water. Now the carbonic acid and the water contain the oxygen employed; and hence we infer that the two volumes of hydrocyanic acid gas contain 2 volumes or atoms of carbon vapour (found in the carbonic acid), 1 volume of nitrogen, and 1 of hydrogen (in the water). So that the combining proportion by volume, or the atomic volume, of hydrocyanic acid, is to that of hydrogen as 2 is to 1.

The composition of hydrocyanic acid may be thus stated:—

2 carbon	12	or	1 cyanogen	26
1 nitrogen	14		1 hydrogen	1
1 hydrogen	1			
	27			27

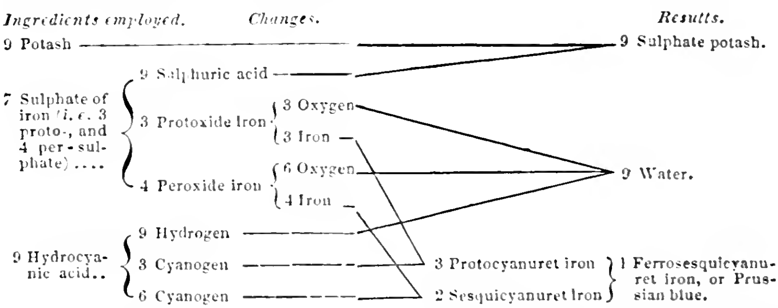
In a few hours pure hydrocyanic acid usually decomposes, and becomes brown; but Dr. Christison says he has kept it unchanged for a fortnight in ice cold water.

Properties of the hydrous hydrocyanic acid.—In this form it is a colourless, transparent liquid, having the taste and smell of the pure acid, but of course in a minor degree. Unless it be very dilute, you may obtain evidences of the combustibility of its vapour thus: heat it in a tube with a narrow mouth,—the vapour which is evolved will be found to burn on the application of a lighted taper. By keeping, it undergoes decomposition, as already mentioned.

Tests.—Hydrocyanic acid may be recognized by the following characters:—

1. The remarkable and well known *odour*. This is said by Orfila to be the most delicate of all methods of recognizing it, since it is very marked when the liquid tests give very slight indications.

2. *Salts of iron.* Add a little potash to the suspected acid; then a solution of some proto and per-salt of iron; the common sulphate of iron of the shops will answer, or the tincture of the muriate, since each of these preparations usually contains both a per and a proto salt. A precipitate is thus obtained, which is liable to considerable variation in its colour, and depending on the quantity of potash, and the kind of ferruginous salt employed; it may be yellowish brown, or greenish, or bluish. Then add dilute sulphuric or muriatic acid, and Prussian blue will appear if hydrocyanic acid were present. The *theory* of this test will be best understood by a diagram; but I may remark that the potash is added to form hydrocyanate of potash, which is decomposed by the ferruginous salt, forming a salt of potash, water, and two cyanurets of iron, which, by their union, form Prussian blue.



Respecting this diagram I have to remark, that all the figures refer to the number of atoms, or proportionals, reacting. You will observe also, that the 7 atoms of mixed sulphate contain 9 atoms of sulphuric acid; for each of the 3 atoms of protosulphate contain 1 sulphuric acid, while each of the 4 atoms of per-sulphate contain $1\frac{1}{2}$ sulphuric acid. I have taken no account here of the dilute muriatic or sulphuric acid used in the testing; in fact, they are only employed to counteract an excess of potash, and are, therefore, not necessary when the proper quantity (which I have assumed in the diagram) of potash has been employed.

3. *Nitrate of silver* is frequently a very useful test; it throws down a white precipitate of the cyanuret of silver, which is distinguished from the chloride by two characters, namely, its solubility in boiling nitric acid (by which nitrate of silver and free hydrocyanic acid are formed), and its evolution of cyanogen gas when heated, known by its burning with a violet or reddish flame. Nitrate of silver is exceedingly valuable as a *negative* test; that is, if no precipitate be obtained on the addition of this salt to a liquid, we may safely conclude the absence of hydrocyanic acid; but if a precipitate take place, we are not, therefore, to infer the

presence of the acid, since many other substances may produce similar precipitates. The *theory* of the action of the test is simple: free nitric acid, water, and cyanuret of silver, are the results. The interchange of elements will be comprehended by these symbols:—

Re-agents.	Results.
$H + Cy$	$\dot{H}$
	$\overset{\cdot\therefore\cdot}{N}$
$\dot{Ag} + \overset{\cdot\therefore\cdot}{N}$	$Ag + Cy$

4. *Sulphate of copper* has been much praised as a test for hydrocyanic acid, but will not bear a moment's comparison with the salts of iron. The mode of applying it is this:—Supersaturate the suspected liquor with potash; then add a solution of sulphate of copper. A greenish blue precipitate is obtained, which, by the addition of a few drops of muriatic acid, becomes (if hydrocyanic acid be present) white. The *theory* of the test is this: by the mutual action of the hydrocyanic acid, excess of potash, and sulphate of copper, we obtain sulphate of potash, oxide of copper, and cyanuret of copper. The formation of these will be understood from the following symbols:—

Re-agents.	Results.
$H + Cy$	$\dot{H}$
	$2\,(\dot{K} + \dddot{S})$
$2\ \dot{K}$	$\dot{Cu}$
$2\,(\dot{Cu} + \dddot{S})$	$Cu + Cy$

To separate the oxide (which gives the greenish appearance to the precipitate), a few drops of muriatic acid are employed: the undissolved cyanuret is white. The objections to the test are, the result not being sufficiently striking, and that a person unaccustomed to manipulation may fail in obtaining the characteristic appearances, by employing either too much muriatic acid (which will dissolve the cyanuret), or too little potash, when no cyanuret is produced.

Physiological effects.—Let us take a general review of the operation of this acid, first on plants, secondly on animals generally, and thirdly on man.

1. *Effects on plants.*—Hydrocyanic acid appears to act as a poison to all plants on which it has hitherto been tried. The phenomena observed are, sometimes a change in the colour of the leaves and flowers, and a diminished contractile power, or at least diminished sensibility to external impressions. Thus if we immerse a stem of *Berberis vulgaris* in dilute hydrocyanic acid, the stamina are no longer capable of moving when irritated. If, instead of the barberry, we employ a stem of the sensitive plant (*Mimosa pudica*), the leaves become insensible to external irritation. Plunging a seed in the dilute acid effectually stops germination. In those parts of a plant poisoned by the acid, the milky juice does not flow from the cells or vessels containing it. By chemical means it has been shewn that the acid becomes absorbed. Ammonia has in some cases appeared to favour the recovery of plants which had been exposed to the vapour of the acid. We shall find that all these phenomena are precisely analogous to those which are produced by the action of the acid on animals.

2. *Effects on animals generally.*—Hydrocyanic acid appears to be an energetic poison to all classes of animals. It is hardly necessary to refer to the effects of individual experiments in proof of this statement; it will be sufficient to add that its action has been tried on the following classes:—

(*a*) *Mammalia*, as man, dogs, horses, rabbits, hedgehogs, moles, cats, mice, rats, porpoises, bears, wolves, lambs, &c.

(*b*) *Aves*, as sparrows, ravens, common fowls, sparrow-hawks, owls, linnets, finches, starlings, magpies, vultures, falcons, &c.

(*c*) *Reptilia*, as lizards.

(*d*) *Amphibia*, as frogs.

(*e*) *Gasteropoda*, as snails.

(*f*) *Annelida*, as leeches.

(*g*) *Crustacea*, as crabs and lobsters.

(*h*) *Insecta*, as flies, bees, wasps, and the stag-beetle.

(*i*) *Polygastrica*, as the vibrio aceti.

The general effects were very similar in all cases, but its action on the cold-blooded animals was much slower, and less evident, than on the warm-blooded. I have given a frog as much acid as I believe would have been sufficient to poison a man, but without any obvious effects. If the heart of a frog be immersed in dilute hydrocyanic acid, it will continue to beat for several minutes.

3. *Effects on man.*—I propose to examine the effects of different doses under three heads:—

(*a*) *Effects of medicinal doses.*—The effects which are sometimes observed resulting from medicinal doses are these: bitter and peculiar taste; increased secretion of saliva; irritation in the throat; frequently nausea; disordered and laborious respiration (which is sometimes quickened, at other times slow and deep); pain in the

head, giddiness, obscured vision, and sleepiness. The vascular system is in some cases not obviously affected, but in others much disordered, though the kind of disorder is not uniform; sometimes the pulse is quickened, at others reduced in frequency. In some instances faintness is experienced. Drs. Macleod and Granville have noticed salivation and ulceration of the mouth during its medicinal use.

(*b*) *Effects of poisonous doses: when fatal, causing slow death.*—Immediately after swallowing the acid a remarkable bitter taste is experienced; this is soon followed by a sensation of faintness and giddiness, with salivation, and succeeded by tetanic convulsions and insensibility; respiration difficult and spasmodic; odour of hydrocyanic acid in the breath; pupils usually dilated, sometimes contracted; pulse small or imperceptible.

When recovery takes place it is usually very rapid, and the whole period of suffering seldom exceeds half an hour. However exceptions, to this exist, in which the symptoms have been prolonged for several hours.

The following case, related by Dr. Geoghegan, is an interesting illustration of these effects:—A gentleman, aged 21, having been for some time subject to an uneasiness in the stomach, not actually amounting to gastrodynia, after having tried many remedies in vain, was induced to have recourse to hydrocyanic acid. He commenced with one minim of the Dublin Pharmacopœia, sp. gr. 0·998: this dose he repeated twelve times the first day, without any perceptible effect. On the following day he took half a drachm, with the same result. The third day his dose was a drachm, which he repeated the fourth day. On the fifth day he took a drachm and a half, still no effect of any kind. On the sixth day he increased his dose to two drachms. In about two minutes after taking this latter quantity, he experienced a sensation of extreme bitterness in the mouth, and having walked a few paces, was affected with great confusion, headache, and loud ringing in his ears. He now with difficulty retraced his steps, and leaning forward on a table became insensible and fell backwards. In this state he remained altogether between three and four minutes, during which time he was violently convulsed. Two drachms of the spiritus ammoniæ aromaticus were diluted with a little water, and applied as quickly as possible to the mouth, but as the teeth were clenched it could not be swallowed. The solid sesqui-carbonate of ammonia was then applied assiduously to the nostrils; its beneficial effects were soon apparent, and he was shortly able to swallow a little fluid. Sensibility now speedily returned, and vomiting supervened, from which he experienced great relief; and at the expiration of half an hour he was quite well, with the exception of pain and feeling of distention in the head, which continued for the remainder of the day.

After he had become insensible, and while leaning on the table, his thighs became rigid, and were drawn up on the abdomen; and as he was about falling, he was caught, and placed on the ground. The upper extremities were then observed to be also rigid, and on drawing them from the side they forcibly reverted to their former position; the eyes were shut, the teeth clenched, and the muscles of the face violently convulsed. It is deserving of notice that the old complaint was completely removed by this extraordinary dose.

(*c*) *Effects of poisonous doses: quick death.*—In these cases the death is so speedy that in the human subject the symptoms have hardly been observed. The phenomena are probably similar to those noticed in animals,—that is, imperceptible pulse, breathing not obvious, or there may be two or three deep, hurried inspirations, insensibility, and death. Convulsions may or may not be present. Dr. Christison states that twenty-five grains of the strong acid, applied to the mouth, killed a rabbit within ten seconds. I once caused the instantaneous death of a rabbit by applying its nose to a receiver filled with the vapour of the pure acid: the animal was killed, without the least struggle. If a drop of the pure acid be placed on the throat of a dog, or applied to the eye, death takes place in a few seconds. Inhaling the vapour decidedly produces death more quickly than any other mode of applying the acid. The presence or absence of convulsions, as connected with the time within which death occurs in these cases, is sometimes of great moment. Some years ago the life of a prisoner almost turned on this point. The following is an outline of the case, which you will find more fully developed in Dr. Christison's work:—An apothecary's maid-servant, at Leicester, was found one morning dead in bed. The body lay in a composed posture—the arms crossed over the trunk, and the bed-clothes pulled smoothly up to the chin. At her right side lay a phial, from which about five drachms of the medicinal hydrocyanic acid had been taken, and which was corked and wrapped in paper. It was suspected that she took the acid to occasion miscarriage, and that the apprentice was accessory to its administration, in consequence of which he was put on his trial. Now here was the question:—Could the deceased, after having drunk the poison, have

time to cork the phial, wrap it up, and adjust the bedclothes before insensibility came on? It was supposed that if the death were of that slow description to allow of these acts of volition, convulsions would have occurred and the bedclothes would have been found disordered. On the other hand, those cases in which no convulsions occur usually terminate too quickly to allow of the above acts.—Judging from my own observation of the effects of this acid on animals I should say these supposed acts of volition were possible, but not probable.

There are two points connected with the action of the acid which are interesting, more particularly in a medico-legal point of view,—namely, the time in which the poison begins to operate, and the time in which it proves fatal. No absolute answer can be given to either of these questions, since the strength and quantity of the acid exhibited, and peculiarities (not known or understood) affect the result. Very strong acid in large doses begins to operate immediately on touching the throat, and death is almost instantaneous. The dilute acid, on the other hand, sometimes does not begin to act for several minutes, and death may not occur for nearly half an hour. Of the seven patients killed in one of the Parisian hospitals, some did not die for forty five minutes. But I have not found the same quantity of the same acid kill in the same time in different individuals of the same species; so that I admit individual peculiarities as affecting the result.

Modus Operandi.—(*a*) *Theory of the local operation.*—The action of hydrocyanic acid on the nerves of the part to which it is applied seems proved from the following fact mentioned by Dr. Christison, that Robiquet's fingers became affected with numbness, which lasted several days, in consequence of having exposed them to the vapour of this acid.

Some symptoms lead to the conclusion that it acts as a local irritant. They are, the acrid impression made by the vapour on the nose and throat, the ptyalism, the vomiting and purging, and the traces of gastro-enteritis sometimes noticed.

(*b*) *Theory of the remote operation.*—That hydrocyanic acid becomes absorbed is proved by its having been detected in the blood, and the whole body having a hydrocyanic odour. But it does not follow that the remote operation is a consequence of this absorption.

The following reasons have been assigned for believing that the remote action of the acid is the result of absorption:—(*a*) Applied to most parts of the body it acts as a poison, but the degree of its energy is in proportion to the absorbing powers of the part. Magendie says a drop mixed with a few drops of alcohol, and injected into the jugular vein, kills the animal instantly, as if he had been struck by lightning. Inhaling the vapour of the pure acid produces almost instant death: it is more active when applied to the serous membranes than to the stomach. Applied to the conjunctiva it acts most energetically, and causes temporary opacity of the cornea, most probably from the cold and consequent condensation, just as pressure produces this effect. When applied to the skin, the epidermis not being removed, its action is usually very slight, in consequence, apparently, of the obstruction this lamina offers to absorption. It appears, that applied to the cut extremities of the nerves, or to a fissure in the spinal marrow or brain, no effect is produced. (*b*) This poison is equally active when applied to the tongue or stomach, after the nerves of these parts have been cut; while, on the other hand, (*c*) the poison is inoperative when applied to any part the circulation of which has been obstructed. The only answer which need be given to all these arguments is, that in many cases death so speedily follows the application of the poison, that it is almost impossible to conceive it to be caused by absorption.

Whether by absorption or by sympathy, its principal action is exerted on the nervous system. The pain in the head, the insensibility, and the coma, seem to prove its operation on the brain, while the tetanic convulsions evince its action on the spinal marrow. The affection of the respiratory and vascular systems is probably the result of its influence over those parts of the spinal marrow which supply these systems with nervous influence.

Dr. Christison has quoted the following case from Wedemeyer to prove the independent action of the acid on the spinal marrow:—"In a dog, the spinal cord was divided at the top of the loins, so that no movement took place when the hind legs were pricked: hydrocyanic acid being then introduced into a wound in the left hind leg, symptoms of poisoning commenced in one minute, and the hind legs were affected with convulsions as well as the fore legs."

Is hydrocyanic acid an accumulative poison? This question is usually decided in the negative, but the correctness of this conclusion is, to say the least of it, doubtful.

It is evident that hydrocyanic acid belongs to that class of medicines which I have ventured to call *cerebro-spinants.* Dr. A. T. Thomson terms it a *sedative.* By some it is classed among *narcotics.*

Lesions of texture.—The post-mortem appearances in cases of poisoning, are the

following:—Glistening state of the eyes, but which, however, is not a constant phenomenon, nor is it peculiar to this poison; the odour of the acid is oftentimes very obvious in the blood, brain, chest, or stomach; from the experiments of Schubarth, it appears to occur principally when death is speedy—that is, within ten minutes after the poison is taken; and *vice versâ*, when life is prolonged to fifteen or thirty minutes, it is unlikely to be met with, since it is so rapidly discharged from the lungs. The venous system is usually gorged with blood, while the arteries are empty: the blood is fluid, dark or bluish black, and viscid or oily. The internal coat of the stomach and rectum, and sometimes also of the air-tubes, is red and easily removed in spots. The vessels of the brain and spinal marrow frequently gorged; sometimes with serous or sanguineous effusion. The lungs in some instances natural, in others gorged with blood.

It has been stated by Magendie, that after death by the strong acid, the muscles are not sensible to the galvanic influence. But this occurs very rarely: indeed I have never observed it, though Dr. Christison has occasionally met with it. Certainly it does not take place when the dilute acid is used; for during several years past, when I have wished to show the influence of the galvanic agency on the muscular fibre, I have always killed animals for the purpose by the dilute acid, and I have never failed in powerfully influencing the voluntary muscles; nor have I once met with a case in which the heart had ceased to beat when the chest was laid open immediately after death.

Cause of death.—In speaking of the cerebro-spinants on a former occasion, I alluded to the immediate cause of death in poisoning by the hydrocyanic acid. In most cases death occurs from the obstructed respiration, as I then endeavoured to show; but in some instances it appears to arise from the sudden stoppage of the heart's action. Sometimes death takes place when we cannot refer it to either of these causes. In the case of the rabbit killed by the vapour of the acid, as already mentioned, death was too speedy to be referred to asphyxia, and on opening the chest I found the heart still beating.

Uses.—We are, I believe, indebted to the Italian physicians for introducing hydrocyanic acid into the list of articles used in therapeutics. In France one of the principal promoters of its use was Magendie, and in this country Drs. Granville and Elliotson. I shall examine its uses under two heads.

(*a*) *Local uses.*—As a local agent hydrocyanic acid has not been very extensively employed. The following are the principal cases in which it has been proposed:—

In *chronic skin diseases*, especially impetigo, prurigo, and psoriasis, it has been recommended by Dr. A. T. Thomson to allay pain and irritation. Schneider, of Dusseldorf, has employed 1½ drachms of hydrocyanic acid, six ounces of spirit, and as much rose water, in scaly diseases attended with severe itching, especially in eruptions upon the genital organs. On several occasions I have tried hydrocyanic washes in prurigo, but without obtaining any obvious relief. Dr. Elliotson says he has found it efficacious in sores behind the ears, and in scabs of the face; and adds, to an irritable face it is very soothing, if employed before and after shaving.

In *cancer of the uterus*, lotions containing this acid have been applied to allay the pain by Frisch, of Nyborg. Osiander has also employed, in the same disease, cherry-laurel water, the active principle of which is this acid.

In *gonorrhœa*, injections containing hydrocyanic acid have been employed with benefit. Schlegel has tried also the cherry-laurel water with the same result. Lastly, the dilute acid has been proposed as an effectual and agreeable mode of destroying vermin.

(*b*) *Remote uses.*—By the Italian writers hydrocyanic acid is regarded as a powerful asthenic or *contra-stimulant*, and therefore peculiarly useful in all diseases attended with excitement. Hence its employment by them in inflammatory affections. Subsequent experience has shown it is of little or no value in these cases. The following are some of the disorders in which it has been recommended:—

In gastro-enteritic affections.—In Dr. Granville's work on Hydrocyanic Acid we are told, "that between the years 1780 and 1796," Hufeland, Haller, Thuessen, Swediaur, Sprengel, and others, used laurel water in stomach complaints, dyspepsia, &c. In 1814, Sprengel, in his Pharmacologia, recommended prussic acid, free or combined, in these affections. In 1819, Mr. (now Dr.) A. T. Thomson detailed a case which led him to infer that this acid would be an important agent in the treatment of dyspeptic complaints: and in 1820, Dr. Elliotson published numerous cases illustrative of the efficacy of the hydrocyanic acid in affections of the stomach. The cases he found relieved by it were—1st, those in which pain at the stomach was the leading symptom; 2dly, those in which the gastrodynia was accompanied by a discharge of fluid, constituting what is called pyrosis, or the water-brash; 3dly, when the excessive irritability of the stomach produces vomiting; and

4thly, those disorders of the stomach which, in some of their symptoms, resemble affections of the heart. I would add to these, analogous affections of the intestines, characterized by pain (constant or periodical), spasm, or purging. I have employed this remedy in numerous cases of painful affections of the stomach and bowels; and though in by far the larger proportion of instances no relief was obtained, yet in some the beneficial effects were most astonishing. I shall not easily forget the case of a gentleman, a relative of one of my pupils. He had suffered for several months excruciating pain in the bowels, commencing daily about two o'clock, and only ceasing at night. It was apparently a consequence of an ague. He had been under the care of several country practitioners, and had tried a number of remedies (including opium and sulphate of quinia) without the least benefit. I advised the employment of the hydrocyanic acid, and accordingly five minims were administered at the commencement of a paroxysm: the remedy acted like a charm: all the unpleasant symptoms immediately disappeared. Several doses of the acid were given before the time of the succeeding paroxysm, but the disease never returned: and after employing the acid for a few days longer he went back to the country completely cured.

Very recently I prescribed the acid for a lady who had suffered for months with gastrodynia, and who was persuaded, from her sensations, she had some organic disease. The remedy acted in the same surprising manner: in a few hours, to the astonishment of herself and friends, this patient was apparently quite well, and she has since had no return of her complaint. As I have before mentioned, in many precisely analogous cases the acid gaves no relief. I know not what are the pathological differences between the successful and unsuccessful cases, and, therefore, the employment of the remedy is to a certain extent empirical. In all the painful affections of the stomach and bowels in which I have employed it, the results have been either the most perfect success, or no obvious effects. I have met with no cases of partial relief.

I have seen hydrocyanic acid given with advantage to allay the vomiting and purging in that kind of cholera which, to distinguish it from the Asiatic or malignant, we now call English or mild. Dr. Prout has found it useful in gastrodynia connected with colica pictonum.

As a remedy in affections of the pulmonary organs, hydrocyanic acid was at one time in great repute. It was said to be capable of curing slight inflammations of the lungs without the necessity of blood-letting: in incipient phthisis, we were told, it either suspended or cured the disorder, while in confirmed cases it smoothed the approach of death; hooping-cough was curable by it; and all the symptoms of spasmodic asthma yielded, we were told, to this acid.

Experience, gentlemen, has shown the value of all these statements. We still bleed in pneumonia: there are now as many victims to phthisis as formerly, despite of prussic acid. Hooping-cough runs its usual course, and spasmodic asthma is little influenced by this energetic poison. Occasionally I have seen the cough and sweating, in phthisis, temporarily relieved, but this is the utmost observed from its employment. Cases of genuine spasmodic asthma are rare, but in two instances in which I have seen the acid employed, no relief was obtained. In allaying cough (especially the kind called spasmodic) I have, on several occasions, found it useful, but having so frequently been disappointed in my expectations, I now rarely employ it in any pulmonary diseases. I have, however, never observed any ill effects arise from its use in these cases, though others have.

It has been employed in *affections of the nervous system*. Cases of hysteria, epilepsy, chorea, and tetanus, have been published, in which this remedy has been found beneficial. I have seen it employed in the three first of these affections, but without obvious relief. It has been proposed in hydrophobia, and I think, were I to meet with another case of this disease, I should try it, employing very large doses, so as to produce serious symptoms, with the view of making a powerful impression on the nervous system, and hoping thereby for beneficial results. But of course the practice would be quite empirical, and as likely to be hurtful as beneficial. This, however, must be the case with any powerful remedy employed, since we are quite in ignorance of the pathology of the disease, and, therefore, have no theory or reasoning to guide us.

In various painful diseases, hydrocyanic acid has been employed internally, as an anodyne—for example, in cancer, tic douloureux, rheumatic pains, &c; and though cases have been published in which its efficacy has been asserted, I believe I only speak the experience of the profession generally when I say that in most instances it is of little or no value.

As an *anthelmintic* it has been extolled by Brera, but the following fact mentioned by Dr. Elliotson, will, I imagine, show you its true value:—"I have frequently employed it perseveringly without expelling one worm, when a dose of calomel has instantly brought away hundreds."

Preparations.—There are only two prepa-

rations of hydrocyanic acid which I think it necessary to notice—namely, a mixture and a lotion.

(*a*) *Hydrocyanic acid mixture.*—The best mode of exhibiting this acid internally is in the form of mixture. I generally give from three to five minims of the acid (said in the shops to be of Scheele's strength) diluted in about an ounce of some mild vehicle (simple water answers very well), and repeated three or four times a day. Gum or syrup and some flavouring ingredient (as orange-flower water, used on the continent) may be added. Some persons give it in almond emulsion.

(*b*) *Hydrocyanic acid lotion.*—Two fluid drachms of the dilute acid of the shops may be employed mixed with half a pint of distilled (or rose) water as a lotion in skin diseases. Frequently about half an ounce of rectified spirit is added, and Dr. Thomson recommends, in addition to this, sixteen grains of acetate of lead. The external use of this acid, in all cases (more especially if there be sores) requires great caution. You must carefully watch its effects on the nervous system and on the pulse. In some cases it causes giddiness and faintness; and Mr. Plumbe says, in two instances it produced intermission of the pulse.

Treatment of poisoning by hydrocyanic acid.—There are four valuable agents in the treatment of animals poisoned by hydrocyanic acid—namely, chlorine, ammonia, cold affusion, and artificial respiration.

(*a*) *Ammonia.*—We are indebted to Mr. Murray for the discovery of this remedy, the value of which has been admitted by Buchner, Orfila, Dupuy, and Herbst. If the patient be able to swallow, the liquor ammoniæ, diluted with eight or ten parts of water, should be exhibited, and the vapour of ammonia or its carbonate inhaled: the latter practice is most important. Orfila says that ammonia is of no use when introduced into the stomach, but that the inhalation of the vapour will sometimes preserve life. I would recommend you to use it in both ways, taking care not to employ it in so concentrated a form as to excite inflammation of the air-passages or of the alimentary canal. In the absence of ammonia the inhalation of the vapour of burning feathers might be employed. I may here remark that ammonia cannot be useful by its chemical properties merely, since hydrocyanate of ammonia is a powerful poison.

(*b*) *Chlorine* is regarded as a more powerful antidote than ammonia. It is recommended as an inhalation, but when the patient can swallow, a dilute solution may also be administered by the stomach. As chlorine gas, or its aqueous solution, is not frequently at hand, you may employ the chloride of lime or of soda, one or both of which is now to be met with in most chemists' shops. A weak solution of either of these may be swallowed; and by adding a little muriatic acid, abundance of free chlorine may be disengaged from them for the purposes of inhalation. The same cautions are necessary in its use as mentioned for ammonia.

(*c*) *Cold affusion* has been strongly recommended by Herbst, and is admitted by Orfila to be a valuable remedy, though inferior to chlorine. Herbst says that its efficacy is almost certain when it is employed before the convulsive stage of poisoning is over, and that it is often successful even in the stage of insensibility and paralysis.

(*d*) *Artificial respiration* ought never to be omitted. Of its efficacy I am convinced from repeated experiments on animals. I once recovered a rabbit by this means only, after the convulsions had ceased, and the animal was apparently dead. It is an operation easily effected, and will be found a powerful assistant to chlorine or ammonia, by enabling it to get into the lungs when natural respiration is suspended. To produce respiration, make powerful pressure with both hands on the anterior surface of the chest, the diaphragm being at the same time pushed upward by an assistant. Inspiration is effected by the removal of the pressure and the consequent resiliency of the ribs.

Mode of recognising this acid in cases of poisoning.—Hydrocyanic acid is a substance which readily undergoes decomposition, and, therefore, it is not likely to be met with in bodies which have been interred for many days. It has, however, been recognized in a body seven days after death, notwithstanding that the trunk had not been buried but had been lying in a drain. In recent cases the acid is readily distinguished by its odour, with which, in some cases, the whole body is impregnated. The tests for this acid which I have already mentioned, will sometimes detect the poison in the filtered contents of the stomach; but the foreign matters present may in some instances prevent the action of these reagents being observed. The best mode of proceeding, then, is to introduce these contents into a tubulated retort, add some sulphuric acid to neutralize any ammonia which might be generated by the process of putrefaction, and distil by means of a vapour or water bath. Test the distilled liquor in the way mentioned in a former part of this lecture.

It has been suggested that hydrocyanic acid may be formed during the process of distillation by the decomposition of the animal matters. But, as Dr. Christison

has properly observed, the objection appears only to rest on conjecture, or presumption at farthest. You will bear in mind also that cheese, under certain circumstances, has been found to contain this acid, as I have already mentioned.

OBSERVATIONS

ON

THE VENEREAL PRACTICE OF BERLIN.

By Alexander Ure, M.D., M.R.C.S.

Late House-Surgeon to the Royal Infirmary at Glasgow.

[Continued from p. 511.]

The condylomata lata are small roundish prominent tumors, commonly of the size of a lentil or pea, with a broad sessile base. They are of a dirty reddish brown or puce colour, and are not, like the acuminata, united in clusters, but uniformly insulated, always maintaining their individuality, constituting small circumscribed eminences. Their usual situation is round the anus and flexures of the nates, upon the glans and frænum, the external margins of the labia, and the integuments of the penis and scrotum. In contradistinction to the former description, these are covered with the common epidermis, or they may more strictly speaking be regarded as a thickening of that tissue which Desruelles has called a hypertrophy of the epidermis, whence the specific name of epidermic might be conveniently substituted for latum, as at once pointing out their formation. Their surface is dry, smooth, and even, emitting no sensible secretion except when excoriated or ulcerated, in which latter condition, if not identical, they have a strong analogy with the *papules muqueuses* of French writers. They seem also congenerous with a symptom of venereal affection, very rare in Europe, but extremely frequent in equinoxial regions, and particularly the West Indies, called *pian.* It consists of moist pustules that show themselves on the bend of the arm, the groin, and the axilla, highly contagious, so that when they attack nurses, they are soon communicated to the children carried in their arms, and manifest themselves on the thighs of the latter.

Epidermic condylomata implanted about the anus might, without due discrimination, be confounded with hemorrhoids. The peculiar livid colour of the latter, together with the previous history of the case, will prevent such an error being committed.

Condylomata may be considered as an accidental tissue, resulting from an increased activity of nutrition in a part which causes its anatomical elements to be morbidly developed, so as to produce an abnormal growth. The increased activity which thus disposes the cellular tissue and capillaries to extend and form new productions, is certainly, in the instance of the epidermic or condyloma latum, referrible to an original and essential affection of the mucous membrane, namely, inflammation with puriform discharge.

In every case which has come before my notice, their development was preceded and accompanied by unequivocal signs of disorder of the mucous membrane, whether in the form of gonorrhœa, balanitis, or leucorrhœa.

No doubt is entertained as to their contagious nature, or that the vehicle of the contagion is the matter secreted. It is probable that the same principle which Jüngken has demonstrated to exist in purulent ophthalmia—a disease of a similar nature to gonorrhœa, and characterized by the development of vegetations on the conjunctiva—may from analogy be extended to the affection under consideration, namely, that the more puriform the secretion, the more contagious it is*.

The following is a well-marked example of the facility with which epidermic condylomata may be communicated by the mediate contact of the matter.

Two females from the country, sisters, the one aged 22, the other 15 years, were admitted as patients with condylomata lata, accompanied with purulent discharge. The younger sister had, besides, ulceration of the throat. Both were simultaneously affected with discharge from the vagina, to which the condylomata succeeded, while sleeping in the same bed with their mother, at that time labouring under like symptoms contracted from her husband.

The endermic, or acuminated condylomata, are believed to be closely allied to exanthematous diseases, and to depend on some constitutional taint; yet it is admitted that they are often a primary affection, co-existent with blennorrhœa, without previous venereal con-

---

* Ueber die Augenkrankheit welche in der belgischen Armee herscht, vom Professor Jüngken. Berlin, 1835.

tamination. Kluge and Fricke agree in regarding them as parasitic growths which must pass through a peculiar course of vitality before they can be made to disappear.

As I have been led into a longer disquisition on the subject of condylomata than was originally contemplated, I shall not enter on the disputed question of their general or local nature, but simply content myself by mentioning that M. Ricord has expressly stated, that when, from other causes than impure sexual intercourse, blennorrhœa is established in the urethro-genital mucous membrane, it is preceded by an erysipelatous inflammation, and attended by the development of small papillæ the size of a pin's head, or granulations, or incipient vegetations*.

Hence it is most likely that when the irritation is quite superficial, we shall have the production of epidermic vegetations; when, on the contrary, it is deeper felt, endermic vegetations will make their appearance.

It appears well established, that the condylomata acuminata, when once called into being, are capable of propagating themselves under peculiar circumstances, in a manner which is not to be distinguished from contagious propagation. Thus it is frequently found that patients admitted with probably one or two vegetations on one side alone of the nymphæ or vagina, will, in a short time, have a crop of similar excrescences on the opposite surface, even although the strictest attention to cleanliness be observed, if due precaution be not taken to insulate the condyloma, so as to prevent the matter that exudes from getting there.

Parts in which a process of ulceration has formerly existed seem strongly predisposed to the imbibition of the morbid fluid, and consequent formation of condylomata.

Treatment of Ulcers.—The cure, properly so called, is preceded by a preparatory cleansing of the bowels for a couple of days, by means of solution of sulphate of magnesia, called the "mistura anglicana." Baths are seldom, and bleeding hardly ever, had recourse to. When ulcers are the only symptom, the patient is ordered half a grain of calomel twice daily. The diet is restricted to three portions of *soupe maigre*, and two ounces of white bread, in the 24 hours. When the sores put on a healthy aspect, then a more generous allowance is given. Much stress is laid on the starving system; and Rust expressly states, that patients should be permitted only as much nourishment as is absolutely necessary for the purposes of life, or maintaining the self-existence of the organism, in order that the parasitical principle of vitality (the lues) present in and dependent on the organism, may be extinguished*. Repose of the body is enjoined, by confinement to bed, as far as can be consistently done, and an equable temperature is kept up in the apartment.

By rigid adherence to the above plan, true syphilitic sores, in the course of from ten to twenty-one days, lose the surrounding hardness and other distinguishing marks, and shew a healthy granular surface.

Simple sores are commonly cicatrized before a fortnight has expired. Where, from constitutional or other causes, over which medicine has no direct control, the sore assumes an indolent character, and cicatrization advances slowly or not at all, local applications are resorted to, such as epithems imbued with a dec. flor. anthem., or sol. sub plumbi; failing these, in some rare instances, the actual cautery is applied. It is occasionally found that, in spite of every topical means that can be put in practice, small, round, perfectly superficial sores, situated on the lower parts of the internal labia, resulting from mere abrasion, will, from their surface being kept constantly moist with the exuding secretion of the part, remain for days, nay even weeks, stationary, retaining a fine florid aspect, but without any disposition to cicatrize. In such cases, by merely uncovering the part, and leaving it freely exposed to the air, the sores will be found completely skinned over after the lapse of a few hours. This same practice I have seen successfully pursued, for the healing up of sores caused by suppurating bubo, when there only remained a small spot in the middle, which had ceased to emit any appreciable discharge.

In reference to the sores produced by rupture of the caruncles at the vaginal orifice, it is of consequence, for speedy reunion, to bring the partially detached caruncle into contact with the abraded sur-

* Journal des Connaissances, Fev. 1834.

* Aufsatze and Abhandtungen, p. 385.

face from which it has been torn, and maintain their apposition by means of little compresses of charpie, keeping the patient in bed with the thighs closely approximated. Although such lesions would undoubtedly heal spontaneously, yet the above precautions are indispensable where it is desirable to prevent irregularity of surface, and a recurrence of the accident under like circumstances.

Where the sores are accompanied with other signs of diseased action (such as bubo, ulceration of the throat, &c.), and where the patient's constitution is good and his health unimpaired, corrosive sublimate is exhibited in preference to, calomel, in the form of pills, either in uniform small doses, as the eighth or fourth of a grain twice daily, or else the old pill of Hoffman, as in the formula of Dzondi, whose method enjoys at present a high reputation in the treatment of venereal disease. His prescription is as follows:—

> ℞ Hydrarg. Mur. Corros. gr. xij.; solve in aquâ distill q. s.; adde Micæ panis albi, Sacchari albi, aa. q. s. ut fiant. Pil. gr. j. No. ccxl. Consperg. Pulv. Cinnam. aut Lycopodii.

Of these pills, four are taken the first day, the third day six, the fifth day eight, and so on, advancing in the arithmetical progression of two on the alternate days, until the patient has come to take 30=1½ gr. sublimate; but if necessary, the medicine may be continued longer and increased farther, as long as it can be tolerated and does not produce any bad effects *. Dzondi has gone as far as three grains; and Handschuh tells us that he has known eight grains taken without inconvenience. The medicine must be taken all at once, and that immediately after dinner, so that it may be assimilated with the chyme and readily absorbed: the larger quantity, however, may be given in divided doses. Such sores as remain unhealed after the cure has been duly gone through, are not to be regarded as syphilitic in their nature, and must be ascribed to some other efficient cause—as scrofula, psora, herpes, &c. His work contains much absurd and fanciful hypothesis.

Gangrenous sores are treated in the old way, by cinchona and mineral acids internally, and externally by vin. camphor.

Condylomata of either sort, when few in number and without other complication, with the exception of puriform discharge, are treated by large doses of calomel, according to the method of Weinhold.

Weinhold's fundamental principle is, that calomel, unless given in great doses and at long intervals, produces ptyalism, which interferes with its action, weakens the patient, and thereby "*disannuls the wonderful, recondite, deep-laying, and hitherto inscrutable, operation of the medicine on the abnormal reproduction* *;" he has introduced what he has chosen to dignify by the title of the great quicksilver cure — *die grosse quecksilber-cur*. The following is his fantastic mode of administering calomel:—The patient takes, a couple of hours before going to bed, on an empty stomach, a powder consisting of 10 grains calomel with 15 sugar; which he follows up with two cupfuls of warm bouillon. After half an hour has elapsed he repeats the same, and if robust, after a third half hour, a farther half dose; so that he swallows, in all, from 20 to 25 grains of calomel, and half a dozen cupfuls of beef-tea. Hereafter he retires to bed. On the following morning he is allowed one or two cups of moderately strong coffee, on the back of which two or three watery stools are expected: should such, however, not take place, it is provided that on the tenth or twelfth hour from his having taken the calomel, a powder, consisting of from 15 to 20 grains jalap, with as much cre. tart., shall be administered, so as to occasion at least one evacuation; after which, rarely any effect on the mouth will be observed.

It is only in persons who have employed often considerable quantities of mercury that salivation ensues; and this is applicable to all the other modes of treatment, we are told. If the patient can remain a few hours at home, in the morning, it will be desirable, in order to promote the cutaneous transpiration; but generally, unless the weather is bad, he can pursue his ordinary avocations. On the evening of the fourth day, the same dose is repeated, divided

* Neue zuverlässige Heilart der Lustseuche von Dr. K. Dzondi, Prof. an der Universitätzu Halle. 1826.

* See Handschuh, p. 193.

into three parts. On the seventh day, the third dose, on the tenth the fourth, on the thirteenth the fifth, on the sixteenth the sixth; after which, on the 19th or 22d, the seventh or eighth dose, dose, with the cure is completed. At the third and fourth dose, it is mentioned that the stomach and bowels become so used to the stimulus of the calomel, as will make it needful to add five or six grains of jalap to the calomel to produce a single evacuation. There is no need of observing any particular difference in the diet*.

The endermic condylomata are expected, under the above treatment, to assume quite a different appearance from what they originally presented; their surface, from being moist and smooth, should become dry and shrivelled, and from a bright glistening red be transformed to a dull earthy or coriaceous hue.

Before the above changes have taken place it is not deemed advisable to extirpate them, which may then be immediately performed by snipping them away with a scissors curved on the flat, and cauterizing deeply the little wound with a pencil of lunar caustic, having previously wiped away the blood from it with a sponge. The cauterization is always accompanied with the most lively pain, seeing that the corium must be fairly perforated by the escharotic, otherwise a speedy relapse will be sure to follow.

Where the condyloma has a broad base, removal by ligature is preferred to that by excision.

Under the use of calomel, given as above directed, condylomata lata disappear without surgical interference. One female afflicted with them was cured after two doses, another after six. The pre-existent and concomitant leucorrhœal discharge is at the same time believed to be modified in its properties, becoming a benign mucous discharge in lieu of a contagious puriform secretion†, which can be soon stopped by the employment of dec. ulmior flor. anthem, &c.

If, on the other hand, the excrescences are more numerous, of longer standing, and accompanied by other signs of venereal contamination, as bubo, &c., the method of Dzondi is straightway put in practice. In the case of endermic condylomata, where the desired local changes are tardy in manifesting themselves, the shrinking and arescence of the surface are to be promoted by means of various topical astringents, such as the sol. nit. argenti or subacet. plumbi, as recommended by Rust and Gräfe, and kreosote, which I saw tried in a few instances. The last seemed to answer only when the condylomata were small, of recent date, and implanted on a smooth lubricated surface, as the internal portion of the nymphæ and prepuce. After a few applications of the pure kreosote, their surface acquired a cream-coloured tint, not unlike the film produced by nitrate of silver on an ulcerated part, and lost something of its unevenness; but no farther effect was remarked on continuing to repeat the application. However, Fricke, who has had great experience in venereal practice, mentions that kreosote frequently applied to the condylomata, not only effectually caused their disappearance, but seemed to prevent their relapse*. If it be asked, why not at once proceed to try to check the process of morbid vegetation, and remove the products, without having recourse to any internal remedies, they answer that in so doing chancres would appear on the wound, or the throat, or nose. This opinion I myself heard asserted by Professor Gräfe in his clinic†.

* Von den Krankheiten der Gesichtsknochen und ihrer Schleimhaute. Halle, 1828.

† The fluids secreted during gonorrhœa and leucorrhœa are held to be of two kinds—a *gutartig*, or benign, and a *bösartig*, or noxious.

* Fricke, as above stated, regards condylomes to be parasitical growths, which must attain their full maturity before they are ripe for removal. Hence such as are rebellious to every means of destruction he allows to grow unmolested until they have reached a certain size, and seem to stop growing, at which stage he finds the ordinary local means succeed in discussing them permanently. From three to fourteen days are requisite.—*Casper'. Wochenschrift*, 1834, No. I. S, 29.

† The pertinacity with which men of acknowledged reputation not only accredit, but promulgate, doctrines which are shewn to be most flimsy and absurd, is no where more palpably displayed than in the present instance; for not only has Fricke demonstrated that condylomes will yield neither to internal nor external means, until they have reached a certain stadium, when the simplest topical astringents suffice (*lib. cit.*); but Handschuh, in one of the best German treatises on this class of diseases, cites Dease's Observations on Venereal Warts, in the Medical and Philosophical Commentaries of Edinburgh, vol. iv. part 3, 1777, in which cases are brought forward of syphilitic excrescences, that did not vanish when the patients had taken so much mercury that they often died of phthisis in consequence of repeated salivation.

The condylomata lata, or epidermic form, when few in number, are soon dispelled by a few doses of calomel, according to the formula of Weinhold, or sometimes even without medicine, by regulation of diet and the digestive organs, and keeping the parts clean. If, however, no attention has been paid to them, and they have progressively multiplied over a wide extent of surface, or have acquired a hemispherical form and porcelanous look, indicating a peculiar inveteracy of character, they are extremely difficult to get rid of. The plan of Weinhold fails to produce any effect upon them, and the bolder method of Dzondi has to be repeatedly renewed, and aided by escharotic applications, of which the *potassa fusa* claims the preference*. Excision is never required for the removal of condylomata lata, even in their most obstinate forms.

The cure lasts, in recent cases, from a fortnight to a month; in what might be called chronic cases, from six weeks to two months are required to secure immunity from their return. In the case adverted to near the beginning of this paper, of the young woman who had been six months under treatment, the condylomata were in immense numbers, occupying not only the internal surfaces of the genitals, but all the surrounding integuments.

It is believed that the method of Dzondi, followed by excision, although in most cases efficacious in the eradication of the endermic vegetations, affords no permanent security against their relapse. For example:—A man towards the latter end of March presented himself at the visit, on account of several small groups of acuminated condylomata on the glans and inner folds of the prepuce, which began to form a fortnight prior to that date, without any assignable cause. Yet three months before that date he had been dismissed from the hospital cured of similar vegetations by means of a full sublimate course, followed by excision.

[To be continued.]

---

* The following solution is much employed for these condylomata likewise:—

R. Hydrarg. Mur. Cor. dr. j.; Camphori, dr. ss. solv. in Sp. Vin. Unc. Apply twice a day.

OPHTHALMIC SURGERY.

TREATMENT OF EVERSION OF THE EYE-LIDS, AND OF HARE'S EYE.

To the Editor of the Medical Gazette.

SIR,

THINKING that a short description of the very ingenious operation for eversion of the eye-lids, and for hare's eye, proposed and successfully performed by Professor Jaeger, of Vienna, might be interesting to some of your readers, I have prepared the following account of it for the Gazette, should you deem it worthy of a place in your able journal. A circumstance that must add to the interest taken in this operation is, that many of the cases to which it is an ample remedy, were classed in the list of incurable diseases by Professor Beer, and other eminent operators. I have seen no account of the operation in any work in the English language. I am indebted for the knowledge I possess of it to personal observation of the practice of Professor Jaeger, and to Dr. Dreyer's account of the operation, in his thesis, entitled "Nova Blepharoplastices Methodus," some parts of which I have verbatim translated.

I am, sir, very respectfully,
Your obedient servant,
WILLIAM BROWN, M.D.
Lecturer on Operative Surgery of the Eye.

317, Argyll Street, Glasgow,
January 1836.

Operation proposed by PROFESSOR JAEGER *of Vienna, for the cure of bad cases of Ectropium and Lagophthalmus.*

When the deformity is considerable in cases of ectropium and lagophthalmus produced by a cicatrice of the skin, both the transverse and perpendicular diameters of the eye-lid are faulty in their dimensions; the perpendicular diameter, or the breadth of the eye-lid, is shortened, and the transverse diameter is elongated. The object of Professor Jaeger's operation is to increase the breadth of the eye-lid, and to reduce the transverse elongation to a proper length. This two-fold aim is accomplished by attending to the following indications: 1. Unnatural adhesions to the edge of the orbit are to be loosened by dividing cicatrices. 2. The abnormal

length of the palpebral margin (the distance between the external and internal commissures of the eye-lid) is to be diminished to the normal length by excising a quadrilateral shaped portion of the whole thickness of the lid. 3. The breadth of the eye-lid is to be restored by detaching the integuments from the bone in the neighbourhood of the orbit, and drawing them upwards or downwards according to circumstances. 4. The wounds made are to be united by sutures. 5. The position of the new eye-lid is to be maintained by the proper application of plasters, compresses, and bandages. 6. After the operation, the patient is to be treated conformably to the principles of surgery.

The older operators only regarded the perpendicular diameter of the eye-lid, the dimensions of which they unsuccessfully attempted to increase. Sir William Adams was the first to point out and perform a successful operation for reducing the longitudinal diameter of the eye-lid to its normal length. His operation consists in the excision of a triangle-shaped piece from the edge of the eye-lid. Adams also attempted, but he failed as many before him had done, to increase the perpendicular diameter of the eye-lid by incisions in the skin. Fricke and other eminent German surgeons have succeeded in rectifying the faulty breadth of the eye-lid by the transplantation to it of a portion of skin from the brow or cheek, but in their operations they have made no provision for diminishing the horizontal diameter. Both objects are effected by Jaeger's operation.

Jaeger's operation is not intended for simple cases of ectropium. It is meant as a remedy for those cases which are the result of a cicatrice of the skin producing considerable loss of substance in the eye-lid, and where the transverse diameter is too much elongated to admit of the lid coming into contact with the ball of the eye. Where the tarsus is diseased in structure, and abnormal in its course, and where the eye-lid is adherent to the cheek, the edge of the orbit, or to the supra-orbital region, this operation is particularly applicable.

Professor Jaeger performs this operation in lagophthalmus, when much of the eye-ball is exposed, and though the disease be unattended with eversion of the affected lid.

It is also recommended as a suitable operation after the extirpation of excrescences or tumor of considerable size from the eye-lid, when it has been found necessary to remove a portion of the palpebra along with the tumor. In cases of this description, the form of the eye-lid may very frequently be restored by the operation about to be described.

During the performance of this operation, the patient may be seated on a low chair, with his face towards the light. A child may be placed in the lap of an adult. Two assistants are requisite. One of them supports the head of the patient on his breast, and elevates the upper eye-lid when the operation is to be performed upon the under one; the other assistant hands the instruments to the operator, and sponges away the blood. The instruments necessary are two fine scalpels, one of which is to be straight and double-edged, and the other single-edged and convex upon its cutting surface. A dissecting hook and forceps, a straight forceps and scissors, are also requisite. In addition, the operator is to be provided with needles, ligatures, court plaster, adhesive plaster, lint, graduated compresses corresponding in size to the circumference of the orbit, and a double-headed roller four or five yards in length.

Before proceeding to the operation, the difference in length of the transverse diameter of the everted and sound lid is to be accurately ascertained by measurement. In the operation, the palpebral margin of the everted eye-lid is to be made to correspond in length with that of the sound lid on the other side of the face.

The next step in the operation on the upper lid consists in taking hold of the everted palpebra about the centre of its edge with the dissecting forceps, or hook, and drawing it downwards so as to put the cicatrice on the stretch, by which the palpebra is adherent to the margin of the orbit. With the convex scalpel, a deep incision is now to be made, which is to take its course about midway between the margin of the everted lid and the superciliary arch. The incision is to be commenced and terminated in sound skin. The wound is to be carried through the whole thickness of the eye-lid, so as to form a slit through which the eye-ball may be seen, the palpebral margin falling down

and leaving that opening through which the eye-ball appears. The length to which this incision is to be carried must depend on the circumstances of the case. In case of wounding the eye-ball, a horn spatula may be inserted between it and the eye-lid, should the operator deem a precaution of this kind necessary.

The narrow strip separating the natural rima palpebralis from the artificial opening formed by the incision just described, is the part from which the reduction of the transverse diameter of the eye-lid is to be made. The size of the portion which ought to be removed is already known from the measurements made before the operation was commenced. The superfluous elongation should be removed from the centre of the strip, and the lines upon which the incisions are to run may be marked with a black-lead pencil or ink. With the aid of scissors and straight forceps this part of the operation is easily effected.

A straight double-edged scalpel is now tobe used for the purpose of separating the integuments from the os frontis. The forceps is to be used in taking hold of the upper lip of the wound, and for separating it a little from the edge of the orbit; the scalpel is now to be introduced upwards and slightly outwards between the posterior surface of the orbicular muscle and the anterior surface of the frontal bone. Having been pushed onwards to a sufficient depth, the blade is to be carried with a sawing motion towards the temple and external canthus, and then towards the median line of the os frontis, without enlarging the original wound of the palpebra, transfixing the skin, or injuring the periosteum. By this process the skin and muscle covering the supra-orbital region and the angles of the orbit are separated from the subjacent parts, and rendered capable of undergoing a change in their position. The depth to which the scalpel will require to be carried, and particularly the extent in the transverse direction to which the integuments ought to be detached, must always be proportionate to the loss of the palpebral substance, and to the varying mobility of the frontal coverings.

The wounds are now to be united by the interrupted suture. The tarsus is to be transfixed by each ligature; but the conjunctiva is to be carefully avoided. The perpendicular wound, by which the undue elongation of the transverse diameter of the eye-lid was shortened, is first to be united by means of two ligatures. An assistant is then to draw downwards, towards the centre of the orbit, the integuments recently detached from the supra-orbital space and from the angles of the orbit, so as to approximate the edges of the wound made in the transverse diameter of the eye-lid. The first ligature is to be inserted in the middle of the wound, in order to act as a central point of attraction upon the surrounding integuments. Should the upper lip of the wound not much exceed the lower lip in length, lateral ligatures may be immediately inserted; if on the other hand it exceed to the extent of forming a fold, this must be removed by the scalpel or scissors, in order that the edges of the wound may be nicely adjusted. The number of ligatures that will be required cannot *à priori* be determined.

Coaptation of the wound having been effected in this manner, the eye-ball is covered by integuments obtained partly from the supra-orbital region, but chiefly from the angles of the orbit; the supercilium will, however, be somewhat more depressed, and describe a smaller and less convex arch than it formerly did.

The operation upon the under eye-lid consists in removing a triangular piece from its edge, after the plan of Adams for the cure of ectropium, and in detaching the integuments from the edge of the orbit by a similar process to that already described for increasing the perpendicular diameter of the upper lid.

The action of the ligatures is to be supported by interposing narrow strips of court plaster. The wounds are then to be covered with small pieces of lint; and the graduated compresses, which have been already described, are to be placed upon the supra-orbital region, or cheek, according as the operation has been done for the restoration of the upper or lower lid. Over the graduated compresses long strips of adhesive plaster are to run, being applied in such a manner as to draw the integuments towards the palpebra, and to approximate them to the bones. When the upper eye-lid has been operated upon, the adhesive plasters may extend from the nape of the neck to the cheek. A roller may be applied to assist the action of

the plasters, if it be deemed necessary. In the after treatment nothing ought to be omitted likely to effect union by the first intention.

SOME REMARKS

ON THE

MODIFICATIONS OF THE SENSES.

To the Editor of the Medical Gazette.

SIR,

HAVING observed in your journal of the 26th of December some remarks by Mr. Noble, on the postscript appended to the paper which you did me the honour to publish a short time since, on the physiology of the fifth pair of nerves, I feel it desirable in reply to offer a few explanatory observations, inasmuch as I perceive Mr. Noble has not only mistaken the contents of the postscript, but drawn conclusions from his own interesting experiments which I conceive to be rather erroneous.

Mr. Noble says, "I have cautiously abstained from expressing any mere views, but confined myself to the facts, and the suggestions of what appeared the legitimate induction." Mr. Noble's own remarks at the conclusion of his paper will decide this point; he there observes, "I make no comment: this case is offered to the profession as an additional fact, tending most strongly, in the opinion of the present writer, to the conclusion, that the function of taste is not a modification of common sensation, and that, in accordance with all the analogy which physiology affords, we must look for a separate nervous supply."

Now, Mr. Editor, allow me to ask what are the contents of this paragraph but *comments* or inferences, deduced by Mr. Noble from his own experiments, including, moreover, two exceedingly important physiological hypotheses; the first assuming that the function of taste is not a modification of common sensation; and the second, that to account for it we must look for a separate nervous supply."

I must beg leave to offer a few remarks on these hypotheses, which I shall endeavour to shew cannot be deduced from any experiments, as they are not in accordance with what we know concerning the nature of the senses, and the connexion subsisting between them. The impression made by the contact of bodies on the senses is by no means limited to those of touch and taste. In order that an impulse be communicated to the other senses, whether by distant bodies acting through a medium, or otherwise, it is still a necessary condition that there be immediate contact. The susceptibility of certain nerves to be excited by the minute and attenuated forms of imponderable matter is, therefore, only an exceedingly delicate power of the perception by touch, of which all the other senses must be considered as merely modifications; and whereas common sensibility is fitted only for the perception of some of the grosser, but still important, conditions of matter. such as extent and impenetrability, even this sense may be so exalted as to serve the purpose of other senses, such as seeing and hearing, should they have been originally wanting, or subsequently extinguished. For instance, some polypi evince a consciousness of the presence of light, although they are utterly destitute of visual organs.

It is on record that blind persons have ascertained the colours of bodies by touch alone. I have just been informed by my friend Dr. Grant, of Richmond, that a case of this kind came under his observation, wherein a blind man was able to distinguish the various colours of woollen cloths by the touch. Another case of the same kind occurred in one of the daughters of Sir Robert W****n. This lady, who had the misfortune to lose her sight, could distinguish the colours of worsted thread, and whilst working could easily discriminate the different shades*. A third instance of the same general nature, although different in its kind, may be mentioned in the case of Mr. Arrowsmith. This gentleman, who was totally deaf, could derive great pleasure from the vibrations caused by musical instruments in surrounding solid bodies, by merely placing his hand in contact with them. These cases afford interest-

* Other examples of this curious faculty in the blind will be found in M. Rodenbeck's interesting paper in the present number.—E. G.

ing illustrations of the affinity between the impressions of touch and those of the other senses.

Mr. Noble's second hypothesis, included in his remark, "that to account for the sense of taste we must look for a separate nervous supply," seems to be derived from the circumstance of the tongue containing separate endowments of taste and touch, and assumes that some other than the lingual nerves are necessary to confer on the tongue one of these sensations.

This question, which has often occupied the attention of physiologists, the case published by me tends, I conceive, to determine, since it was found that the destruction of the lingual branch of the fifth pair involved at the same time that of the senses of taste and touch. It appears, therefore, quite unnecessary to "look for any other nervous supply." The view here taken agrees with the theory of one of our greatest authorities, Sir Charles Bell.

The nerves of the fifth pair being compound and ganglionated, giving both sensation and motion, doubtless contain filaments specially modified for the purpose of taste also; and as compound nerves derive their origin from separate portions of the central mass, it is not at all surprising that one portion of the nerve may be paralyzed, without implicating the other, a circumstance often illustrated by paralyzed parts possessing either motion without sensation, or sensation without motion. A distinction must likewise be made between the effects of partial paralysis, and the total destruction of a nerve. In my patient's case the post-mortem examination, carefully performed in the presence of Dr. Roget and Mr. Robert Wade, ascertained the total destruction of the fifth pair, which had completely extinguished the senses both of touch and of taste. Mr. Noble's second hypothesis must consequently be erroneous. Much credit is, however, due to him for shewing the distinctness of the functions of taste and touch, which his interesting experiments tend to demonstrate.

A case in illustration of this theory has been brought to my notice by the kindness of Mr. Robarts, in a woman aged about 45 years, who has nearly lost the common sensibility of the whole right side of the face, including the eye, nostril, and tongue, which latter part, however, retains a slight perception of touch; but the taste on that side is entirely abolished, so that neither vinegar, salt, nor ordinary aliments, produce the slightest impression,—a circumstance exactly agreeing with the experiments of Mr. Noble.

In conclusion, it appears necessary only to remark, that although the experiments of Mr. Noble tend to demonstrate the distinction of the senses of touch and taste, in which view I fully concur, and have briefly illustrated it by an appropriate case, yet the deductions which he has drawn from them respecting the modification of the senses, and the nervous supply to the tongue, are at variance both with the facts detailed in my paper, and with the opinions of almost all the celebrated physiologists of the present day, whether of the French or English school.

I am, sir,
Your obedient servant,
JOHN BISHOP.

38, Bernard-Street,
Jan. 15, 1836.

LETTER ON THE BLIND,

By MONSIEUR A. RODENBECK,
Member of the Chamber of Deputies, Brussels.

[The following letter was recently sent by the author to a surgeon in London, by whom it has been forwarded for insertion in the Medical Gazette. It adds greatly to its interest to be aware that the writer has been blind from early life.]

SIR,—In our last conversation, you asked me for some information on the blind. I believe I cannot answer you better than by communicating my reflections on this subject, which are unfortunately the fruit of a very long personal experience.

The greater part of the writings which have been published on the blind are full of exaggerations and errors. It belongs to one of their fellow-sufferers to judge of them without prejudice, and to appreciate them properly. Without partaking of the prejudices consecrated by time and habit, I will endeavour to found my opinion on facts, and to weigh with equal frankness my praises and criticisms.

Education, the first benefit of civilization, and an abundant source of the purest consolations, becomes for the blind an absolute necessity, and the more

attractive, because, knowing the advantages to be gathered from it, they feel more keen regret at being deprived of it. Sight is, of all the senses, that which procures to man the most delicious sensations; it is always at the expense of happiness that we cease to enjoy it, though the development of other senses, and especially that of the touch, makes up to us in some manner for the privation of light. I do not speak here of blindness in a figurative sense,—that species of blindness imparts felicity, and our drawing-rooms are crowded with happy blind men of this kind.

The idea of rendering the blind useful to society and to themselves, belongs more particularly to M. Valentine Hauy, who erected, in 1784, the first blind school which ever existed in Europe. Doubtless you will learn with pleasure the accident which induced him to devote himself to their instruction; he relates it as follows:—"A novelty of a singular kind," says M. Hauy, "attracted, some years ago, a concourse of company to the entrance of one of those places for refreshment in the public promenades, where our honest citizens go to refresh themselves for a moment at the close of day. Eight or ten poor blind men, with spectacles on their nose, seated in a row at a desk which held music, executed a discordant symphony, which seemed to excite the mirth of the bystanders. A very different sentiment affected me, and I conceived at the moment the possibility of realizing, for the advantage of those unfortunate men, the power and the means of enjoying the art of which they had only a limited and ridiculous idea. The blind (I said) know objects by the diversity of their forms; why should they not distinguish letters —an *A* from an *I*, if these characters were rendered palpable?"

Soon after, M. Hauy submitted to the judgment of the Royal Academy of Sciences a memorial, in which he explained the methods which he proposed to employ for the instruction of the blind; consequently, an asylum was opened to them. They were for the most part wandering on the highways, a prey to ignorance and misery. They were now collected in a residence by the cares of benevolent persons, and withdrawn from that moment from the contagion of vice. The times were favourable to the foundation of such an establishment: philanthropy had become at that epoch a sort of fashion, which all the world followed, some from humanity, others from vanity. There was a crowd of subscriptions for the new school, and by the magic of fashion the blind became the subject of every conversation. M. Hauy gave up his whole fortune for their benefit. The whole life of this worthy man was one long act of beneficence, and it is to this illustrious scholar that the blind are indebted for being no longer considered as a misfortune to their family. Never—no, never—shall I forget this good man; and I acknowledge here, in the name of all the blind, an eternal gratitude to him who was their protector and their guide. I shall not quote to you here the brilliant success which has crowned the efforts of this learned professor, but I delight to recal to you, that by his ingenious contrivances he has in a manner given a new existence to the blind. To withdraw these interesting beings from the painful and dangerous burden of idleness—to make them find in labour a resource against want—to console them for their privation—such is the happy result of the method invented by M. Hauy.

The plan consists principally in enabling blind persons to execute different labours relative to arts and trades —such as making cordage, spinning wool and flax, making rush and straw bottoms to chairs, baskets and mats, knitting stockings purses, fishermen's nets, &c. In short, he has contrived to enable them to perform almost every kind of handicraft. These last advantages are suitable to the blind who belong to poor families; as for those who form part of the upper classes, they are enabled to learn reading, writing, arithmetic, geography, music, different games at cards, draughts, chess, dominos, and all the little manual arts which are used as amusements in society. In one word, they are inspired with a taste for employment; and ornament their memories (generally so excellent and methodical) with the finest literary extracts. By the help of this happy system, they forget their misfortune, and thus are restored to society men who frequently form some of its greatest ornaments; for experience has proved that they are infinitely more cheerful than

could be supposed possible from the nature of their calamity. I have above enumerated the several kinds of knowledge that the blind can acquire: this information is immense; but as mankind are always fond of the marvellous, ancient authors have exaggerated the talents and the defects of the blind; and the moderns, without examination, and without reflection, have repeated their errors. It is thus that there has been spread and propagated in society a variety of mistakes, either from the unworthy desire of astonishing men (and many like to be astonished), or to captivate the vulgar, who admire exaggeration and hyperbole.

An idea which has been generally received is, that the loss of one sense adds to the perfection of the other senses. This assertion is bold; I will say more—it is totally absurd. The perfectibility of the touch amongst the blind, called so ingeniously the geometrical sense, is only acquired by the continual exercise of this sense; necessity, the powerful mover of all our actions, is the sole cause of the superiority that we have in this respect over those who are. If these last practised more the sense of tact, the pre-eminence would be no longer in favour of the blind. If the prejudice which I have just observed was correct, it would follow that we might establish as a principle, that the loss of two or three senses would be attended by a moral compensation. It is not so. M. Hauy mentioned to me the case of a young girl, deaf, dumb, and blind, whom he tried to instruct without being able to succeed. Instead of having a double degree of intelligence, this unhappy creature was in some measure deprived both of intellect and feeling. All that has been said of the prodigious memory of the blind is equally erroneous: this superiority is only caused by exercise and necessity, and not by a *mnemonica*, as some authors pretend. Another cause of their great memory is that blindness prevents all distractions caused by sight. I must add, that it is of the greatest importance that the memory of the blind should be strengthened by exercise. This faculty is so useful to all men, that Bonaparte, impressed by its truth, declared that a man without a memory was like a city without a garrison.

A delicacy of touch and a good memory must form the basis of the education of the blind; and it is upon these two qualities that M. Hauy has founded his system of instruction. Reading by means of prominent characters and mutual teaching, have been equally employed by him from the origin of his Institution. All these methods are ancient, but have been modified in modern times.

Many persons believe that the blind can distinguish colours by the touch, and some well-informed men (at least on other subjects) have often asked me questions on this point. I can assure them that it is absolutely impossible; but the blind have some other means of distinguishing colours, although imperfectly. I knew a blind man whose sense of smelling was so exquisite, that by rubbing a piece of coarse blue cloth with his hand, he smelt indigo, and thence drew the conclusion that the cloth was of a blue colour. Another blind man had a habit of chewing any article of stuff that was presented to him, and was enabled by this means to guess the colour, particularly when gall-nuts had formed a part of the dye.

I met, one day, a blind Frenchman wandering about the boulevards of Paris; he was surrounded by a troop of citizens, who were all in ecstacies at perceiving that a man deprived of sight could ascertain colours. This man held in his hand a wooden octagon, whose eight sides were each painted of a different colour. When the curious bystanders placed his finger upon the surfaces, he cried out this side is red, or green, or blue, &c.; but when he was asked for some money, the crowd disappeared, and I asked permission to examine his octagon. I remarked distinctly with my finger, that one of the surfaces was highly polished, whilst others were rough and sharp to the touch. These irregularities were produced either by the particles of the paint, of which some are infinitely coarser than others, or by the labour of the carpenter, who, I am inclined to believe, had contrived with great art different marks or signs easily recognized by the touch. Such are the secrets of those blind persons who pretend to find out colours by the touch or smell. To discern the truth, it is necessary to place in their hands articles which they have not previously studied in the company of a person who sees; you will soon be convinced of their

ignorance. For those who have never been blessed with sight, this ignorance is no privation: — they have no regrets, for they cannot regret what they have never known. It is for this reason that persons blind from birth are more happy than those who become so by accident.

Metaphysicians have endeavoured to give an idea of colours to the blind by artificial means, which consist chiefly in comparing the sounds of different instruments with colours. Imagine, they say, that the brilliant sound of the trumpet has the same effect on the ear that the colour of scarlet has on the eyes. This method is ingenious enough, but is incomplete, and devoid of exactness. This ignorance of the blind, in all relating to colours, renders the history of the celebrated mathematician, Saunderson, who was blind from his birth, still more extraordinary. He gave a course of lectures on optics with the greatest success; but who, notwithstanding his great talents in demonstrating the laws of catoptics and dioptics, could never comprehend or conceive the colours of the prism, or the verdure of the foliage*. His comparison of the resemblance of the visual ray to a fine elastic thread, is more exact than that of the resemblance of the sound of the trumpet to scarlet. The blind have no positive ideas of ugliness and beauty, but as their eyes are at their fingers' ends, the sense of touch is employed by them with more or less success.

The blind easily discern the softness of the skin, leanness or plumpness, firmness of muscle, pleasant or unpleasant breath, the form of the face, &c. He distinguishes if the nose, the mouth, the chin, &c. have proportions suitable to the received rules. But neither the blind Du Puiseaux, nor the learned Saunderson, have been able to judge of the whole appearance of a face or figure; they have never known the eloquence of the eye; they have never felt the power of an expressive and tender glance to delight and intoxicate the senses. And Saunderson, although a learned professor of optics, has never conceived why lovers of both sexes, on whom nature has bestowed fine eyes, are almost certain of pleasing.

From what I have just proved, it appears that the charm of a good pronunciation, and a sweet and sonorous voice, must be the ideal of beauty to the blind. It is so, when they have heard from a clear-sighted person that the lady in question is pretty; but if, on the contrary, they are told that she is plain, the sentiment of self-love quickly dissipates their illusion; consequently their notions of the physical beauty of individuals are only borrowed, and they ought to refer to a third person. In this they resemble those gifted with sight, who hear of some one whom they have never seen, and who are contented with what they are told, till an opportunity arises of judging for themselves. It sometimes happens that the blind do not ask for information on the beauty or the charms of the exterior of an individual whose voice, from its agreeable or repulsive quality, leads them to create an imaginary face which corresponds with it. The ardour of their imagination, frequently even extravagant and romantic, leads them to suppose the individual in question either a Venus or hideously ugly. The quickness with which the blind perceive the connexion between the sound of voice and the character of the individual, is really remarkable: those who are well informed, read the scale (if we may be allowed the expression) with a quickness of perception and a penetration rarely possessed by persons gifted with sight. The blind recognize deformed persons by the sound of the voice, which will not surprise those who have some knowledge of physiology; but what is still more extraordinary is, that very lately, in an evening party at L'Hôtel de Suède, at Brussels, a blind man was able to tell the age of every one in the room from the sound of their voices; and this with a precision which astonished all present. Amongst the party there were some pretty women, but the gallant blind man willingly deceived himself, and made them at least five years younger when he told their age. He knew that the fair sex approve of such errors. He recollected, without doubt, the beautiful woman of high rank, who preferred remaining a widow, as a second marriage would compel her to exhibit the date of her birth; and the famous coquette who lost her law-suit rather than shew the judge a paper which exactly proved her age.

* See Diderot's Letters.

Some blind persons have the four senses in such exquisite perfection, that if they hear any one speak they directly approximate his height; will find out the size of an apartment—if it contains much furniture; and at their own houses will discover if any article has been displaced. They know, by the remembrance of sounds, persons whom they have heard speak formerly. They can tell if they are in a street or a blind alley, in a large or a small room. They calculate the proximity of the fire from the degree of heat; the fulness of vessels by the noise made by the liquor when pouring into another cup; and the neighbourhood of bodies by the action of air on their face. Their hands are scales for weighing; they judge correctly of the duration of bad weather; recognize places where they have formerly been introduced. They feel correctly the vicissitudes of the atmosphere, and remark, by the different action of the rays of the sun on their face, when a cloud obscures its disk. All this is doubtless astonishing; but to walk alone in Paris is still more difficult. I know several who possess this audacious skill; amongst others, the intelligent Leré and the bold Manne. I recollect meeting them passing over the most dangerous crossings with only a stick to guide them *. I do not believe that the blind Du Puiseaux, or Saunderson himself, have done as much as these adventurous Frenchmen.

After having spoken of the talents of the blind, it now remains to examine the defects with which they are reproached: I have said that they have been much exaggerated, and I hope to prove the truth of what I advance.

First, they are accused of irreligion: this reproach appears to me unfounded. It is perhaps true that at church they have less fervour and less devotion than those who see; but may we not believe that the reason that they have less apparent piety, is that their imagination is not struck by the pomp and majesty of religious ceremonies? All the magnificence of the worship of the Divinity, this language, which speaks only to the eyes, loses its influence on the blind; and the pious exterior observed with so much art by the many, is a pantomime of which they must necessarily remain in ignorance. Three-fourths of the blind whom I have known (and the number is very great) were so far from being irreligious, that they felt more than others the necessity of the love of God, and their hearts sought with avidity for religious sentiments, which could alone console them under their misfortunes: but strongly as they are devoted to an enlightened religion, even more strongly do they abhor hypocrisy, for sincerity is one of their peculiar qualities; and they equally abhor cant and irreligion.

At the beginning of the Restoration, these calumnies were propagated in France, by some active impostors who had an interest in changing the disposal of the property of the Institution for the Blind. It is possible, also, that during the course of the revolution, this part of their education was not attended to sufficiently; and as they had been neglected in not teaching them some dogmas of their faith, some persons consequently concluded that the blind had no faith in religion. All must be learnt in this world, even virtue itself; and since such is the law of nature, of course the blind are not excepted from the general rule, as their minds, their hearts, and all their sensations, require more culture and more assiduous care than those of other human beings. There is, however, a singular quality which is innate amongst the blind—the horror they have of theft. This sentiment has been attributed to the difficulty they would experience in thieving, and to the natural anger they feel at being unceasingly exposed to the deceptions of others; but even supposing there is a little egotism in their manner of acting on this head, let us observe, however, that in examining the registers of the criminal courts, it is astonishing (considering the amazing number of blind now existing) not to find a single instance of one condemned for theft.

I have not yet mentioned all the faults assigned to the blind; amongst the accusations laid to their charge, I ought to place in the first rank the want of modesty with which they are accused, as well as the ingratitude, the want of sensibility, and the suspicion which they are supposed to possess: to the first charge I answer, that it is from ex-

* At Paris, in a very thick fog, some blind men of the Quinze-Vingts served as guides to those who saw, and even conducted them to their dwellings.

treme licentiousness that so much stress is laid on the appearance of modesty; that the Old Testament does not display that reserve in words which has been carried so far in our times; and, in short, that in Italy and at Rome, even the angels are unattired in the churches. Besides, the number of the blind who have been educated, is certainly not more than one in five hundred; therefore I confess that the great majority cannot have that sentiment of propriety which makes the charm of society; but are the lower classes generally distinguished for modesty? Is not ingratitude (the vice of little minds) common to this class of men? In regard to sensibility, if this native faculty appear less lively amongst the blind, it is because they are not moved by exterior demonstrations—because cries and complaints are necessary to make them acquainted with suffering, and to make them compassionate the sufferer; but they certainly are ignorant of those grimaces of etiquette, that parade of sensibility so happily called *sensitiveness;* they certainly do not go into convulsions on every trifling accident. It must be owned also that the word sensibility is very elastic; for one often sees a woman shed floods of tears at a theatre over an imaginary sorrow, and refuse on going out the smallest alms to a poor infirm old man. I knew a man of great sensibility, at least in his own opinion, who beat his groom in the most horrible manner. A moment afterwards he was miserable, and gave him a piece of gold by way of consolation. Other individuals go to criminal executions to sob in public; but the blind never display such scenes, because the sorrows addressed to the eyes are not felt by them. In regard to suspicion, with which the blind are reproached, this quality is in fact a necessary consequence of their position in society; they can never rely entirely on any individual; and as their moral vision is remarkably fine and subtle, they easily discern falsehood, and he who has once deceived them loses their confidence for ever.

Without dwelling longer on this subject, it appears to me that instead of exciting these clamours against the blind, all those who have the blessing of sight ought especially to defend them, and to display the greatest indulgence towards them; for be assured there does not exist, at least in this world, a greater misfortune than that of blindness. If I am not to be believed, ask those Belgian soldiers, 2000 in number, who are condemned to eternal darkness; they would have faced death without changing colour, but their courage could not support them under so great a misfortune without giving way to tears and despair.

If (as we are told) some precautions with regard to health, added to the suppression of neckcloths, would be sufficient to extirpate this ophthalmia, let us implore our king, who is a philosopher as well as a citizen, to put a stop to this devastating plague, and to assuage the terrible anguish of parents whose children are enrolled under his banners. If these lines should contribute to so great a blessing, how happy shall I feel to have snatched some victims from the calamity in which I am myself a fellow-sufferer.

Before terminating my letter I shall endeavour to give you an account of the manner in which the blind read, write, calculate, and understand geography. I shall in a few lines acquaint you with the methods invented by M. Hauy; those who wish to make use of them may examine these methods at leisure in the establishments for the blind at Paris, at St. Petersburgh, at Berlin, at Amsterdam, and even at my residence*, where I shall have great pleasure in communicating them, more particularly to my fellow-sufferers.

The blind write by means of a pen or stylet of iron. For this purpose they must have a table or board, upon which is fastened with hinges a frame of copper or iron, furnished with fiddle-strings, or thin slips of metal, placed from side to side at equal distances, so that they can write between the regulator, which is formed by two rods of metal, or two fiddle-strings. To write thus, you place on a sheet of leather a sheet of letter-paper: upon this you place some paper blackened with soot and grease: over all this a sheet of blank paper is laid. This operation finished, the frame is lowered, and they write with the iron stylet between the lines of the regulator. It is necessary to press very hard, to

* At Roneres, in Western Flanders.

form at once two writings, of which one is black, for the use of those who see, and the other white, and in relievo, serving as a copy, which the blind can read with their fingers.

To learn to read and to calculate, we make use of letters and figures of lead in succession, which are placed in holes regularly cut out in a board, either for reading or for calculation. With these leaden characters they print in relievo, and form books, which the blind read with the finger. The same method is used for music.

As for geographical maps, they are also in relievo. There are many modes of preparing them; the simplest is to sew a little circumference on the silk or limits of the different countries. All the maps which I *touched* at Paris, and in many other blind institutions, are imperfect; but thanks to the talents and the politeness of Mademoiselle Langlart and Madame Lefebvre-Muxaini, at Lille, I have at last perfected mine, so that now I recognize by the touch, towns, rivers, seas, the degrees of latitude and longitude, and even the scale to measure distances. As for playing cards, the signs are pricked on the card with a needle, and are so distinct that the blind man who is accustomed to them recognizes them as quickly as those who have eyesight.

As there exists a sort of brotherhood of misfortune between the dumb and the blind, I am often asked if I had rather be deaf and dumb than be deprived of sight. All blind men answer this question by declaring that they prefer the loss of sight. When the deaf and dumb are asked, they declare that they prefer their own infirmity. But observe, I beg, that the blind are much more cheerful than the deaf and dumb; these last are incontestibly much more out of society; their means of communication are a most fatiguing labour for those who have the use of their faculties, though the pantomimic action required is both curious and interesting. This is not the case with the blind. Conversation, that great charm of society, is open to them: to converse with them is not more difficult than to converse with the rest of mankind; besides, the intelligent blind man knows very well, that as he has one sense less, he ought to endeavour to possess higher moral qualities as a compensation.

I conclude, then, that the blind who are in circumstances sufficiently easy to subsist without any labour, are more happy than the deaf and dumb, especially as their children do not inherit their affliction, as is generally the case with those who are deprived of hearing and speech. But I must add, that for poverty it is better to be deaf and dumb, as those who are deprived of these powers very easily become mechanics: no handicraft is impossible to them, and under this head the comparison is all in their favour; but it is remarkable that the blind are longer-lived than the deaf and dumb. It will hardly be credited that persons thus differently afflicted can converse with each other. The blind man must learn their alphabet, and the signs that represent their ideas. By the help of these methods he writes in the air, or makes signs, which are comprehended by the deaf and dumb, who, in their turns, write upon the back, or in the hand, of the blind man. I use this method myself in conversing with a most intelligent man who is deaf and dumb, who was educated by the Abbé Sicard, and who has had private lessons from the celebrated Massieu. This interesting man is M. Lauwers, of Ostend.

I do not know if you are aware of an establishment for the blind in Holland, founded by Louis Bonaparte. Here we do not enjoy this blessing; but I venture to hope that our present august monarch, who pays such devoted attention to the instruction of his subjects, will permit the lights of science to illuminate the minds of the blind in Belgium, and to enable them to participate in the benefits of civilization.

I do not know if in this letter I have had the good fortune to convince you, and to inspire those who read it with some benevolent feelings for my fellow-sufferers. I have endeavoured to compensate by accuracy as to facts for the errors I may be justly reproached with in regard to style and purity of expression; but to support my opinions, and to shew that I have advanced nothing without proof, I will give you an account of some celebrated blind persons, and of some whose names, hitherto unknown, are nevertheless quite as worthy of our respect and admiration.

[To be continued.]

ON THE CAUSES AND TREATMENT

OF

PROLAPSE OF THE FUNIS IN LABOUR.

By R. T. Hunt,

One of the Surgeons to the Manchester Lying-in Hospital.

The frequent termination of those labours which are complicated with prolapse of the funis in the death of the child, not only when the case has been left to the unaided natural efforts, but also when every assistance that art could afford has been rendered, sufficiently evinces the importance of investigating the various circumstances under which this untoward accident occurs.

The present time appears favourable for such a communication, the publication of my colleague, Mr. Roberton's, remarks "On the Causes of Prolapse of the Funis in Labour*," having recently directed the attention of the profession to this subject. I should not, however, have ventured to obtrude any remarks of mine on the public, had I not, in consequence of my office as surgeon to the Lying-in Hospital, during nearly eight years, possessed considerable opportunities of investigating subjects of this description.

Many circumstances have been noticed as conducing to prolapse of the funis in labour; the chief of which may be arranged under the following heads:—

1. Unusual mobility of the fœtus in utero, dependent either upon its small size, the too great quantity of liquor amnii, or the too great length of the funis.

2. Presentation of a part of the fœtus which has not entered the brim of the pelvis in such a manner as to entirely occupy it at the time the rupture of the membranes and escape of liquor amnii occur.

3. Premature rupture of the membranes, and their rupture when the mother is in an unfavourable position.

4. Distortion of the pelvis.

5. The pelvis being considerably above the standard size.

6. Presentation of the abdomen.

7. Insertion of the placenta in the neighbourhood of the cervix uteri.

8. The funis becoming twined round some part of the child.

1. Unusual mobility of the fœtus in utero.

If a number of females at the full period of pregnancy, but anterior to the commencement of labour, are carefully examined by pressure with the hands on the abdomen, it will be found that the extent of motion of which the fœtus is capable varies very considerably. In some the head of the child can be distinctly felt in succession at the epigastric, the right and left lumbar regions, within a very short space of time; whilst in others the head seldom changes its position in utero, and with much less rapidity. This extent of motion in the former instances depends, according to Madame Lachapelle*, upon the small size of the child in relation to the uterus, the great quantity of liquor amnii, and the great length of the funis. Unusual facility of motion in the fœtus may be considered as predisposing to all those presentations which are termed preternatural, whilst the cause which in such cases determines the descent of the funis, viz. the untimely rupture of the membranes, may occur even in instances where the funis has not been previously found presenting between the head and os uteri, but is situated, in consequence of this mobility of the fœtus, within reach of the current of fluid passing into the vagina. I feel surprised that Mr. Roberton has omitted to notice this mobility of the fœtus as a cause of prolapse; for in one of his cases he says, "I found the funis pulsating in the vagina in a great number of short turns; these passed down, in contact with the promontory of the sacrum, and consequently *threw the head forwards on the pelvis*†." Much as I attribute to the motion of the fœtus, I certainly am at a loss to conceive how the soft funis can by its descent throw the head to either one part of the pelvis or another.

2. Presentation of a part of the fœtus which does not fully occupy the brim of the pelvis.

In presentations of the upper or lower extremities, the presenting part is so small in proportion to the size of the brim of the pelvis, that the funis may

* Med. Gaz. Jan. 9th, 1836, p. 558.

* Lachapelle; Pratique des Accouchemens, tome iii. p. 217. 1825.

† Med. Gaz. *ut supra*, p. 560.

easily present at the os uteri with it, and as the pains increase in force, the hand, foot, or other part of the presenting extremity, being frequently propelled against the membranes, which are always tense during uterine contraction, may thus cause the untimely rupture of the membranes, independent of any interference on the part of the attendant, or any unfavourable position of the mother, although either of these circumstances will accelerate the giving way of the membranes. These remarks are less applicable to breech presentations, in consequence of the size of this part more nearly approaching that of the head. All these presentations are referrible, in a greater or less degree, to unusual mobility of the fœtus in utero. Should the head enter the pelvis in an unfavourable direction—with its long diameter, for instance, corresponding with the short diameter of the brim—the length of time which must elapse before the head is, by means of the powerful action of the uterus, compressed into the brim, so as to occupy it fully, not only places the life of the child in imminent danger, but the imperfect adaptation of the head to the inlet in the meantime also materially conduces to the prolapse of the funis. Such a case is related by my colleague, Mr. Radford, in the Medical and Surgical Journal for January, 1834. In this instance the midwife had ruptured the membranes, in order to ascertain the presentation. The funis shortly prolapsed, and after the death of the child, the delivery was completed with difficulty by means of perforation. Mr. Radford attributes the remote situation of the presenting part of the child, in such cases, to the undeveloped condition of the cervix uteri, and deprecates the rupture of the membranes with the view of discovering the presentation. "If the membranes," he continues, "are ruptured before the uterus is prepared for action, the head will rarely enter the pelvis favourably; for previous to the sinking of the uterus and its contents into the superior aperture of the pelvis, the child is easily moveable in the waters. This floating of the child may be readily ascertained, when it becomes necessary to make an examination per vaginam, before the completion of pregnancy. But when the uterus has undergone the preliminary changes preparatory to active labour, the head of the child may be felt through the substance of the uterus, as a globular body, presenting considerable resistance to the finger. At this period it assumes its final position in relation to the pelvis*."

Mr. Roberton also refers, in the commencement of his paper, to these preparatory changes of the uterus, and their influence on the position of the head in the pelvis. He remarks, "If in this stage," (viz. the head having been located in its natural situation in the pelvis), "during a pain, the waters escape, then the head of the fœtus instantly descends into contact with the lips of the womb, and closes the opening." And further on he adds, "Such is the mode by which nature shuts the mouth of the womb during labour, whereby its floating contents, viz. the funis and remnant of the waters, are kept from escaping into the vagina †."

Now it appears to me, that if the head is properly located in the inlet, so as to occupy it fully, there is no necessity for this closure of the os uteri to prevent prolapse of the funis from taking place; and in those who have borne many children, the lips of the os uteri are frequently so loose that two fingers can easily be interposed between any part of them and the fœtal head, and yet no prolapse of the funis occurs. It is, then, this adaptation of the head to the inlet of the pelvis which prevents the funis from prolapsing, unless it has fallen down before the head has occupied the brim,—a circumstance which has already been noticed as depending upon unusual mobility of the fœtus.

3. Premature rupture of the membranes has been so long admitted as one of the causes of prolapse of the funis, that it appears unnecessary to notice this subject at length on the present occasion; and the same observation will apply to the influence of the position of the mother at the time of the rupture.

4. Distortion of the pelvis.

Several authors have noticed the connexion of prolapse of the funis with pelvic deformity. In such cases at least as long a time must elapse previously to the fœtal head properly occupying the brim of the pelvis, as in the instances of malposition of the head already noticed as conducing to prolapse.

Baudelocque* observes, "Le risque

---

† Medical Gazette, p. 558.
* L'Art des Accouchemens, édition 6me., tome i. p. 497. 1822.

que court l'enfant dont le cordon est sorti, n'est jamais plus grand que quand le bassin de la mère est un peu reserré, puisque la pression que doit y éprouver ce cordon est alors plus forte."

And Lachapelle * remarks, "Ainsi une obliquité quelconque de la tête et de la totalité du fœtus, de même qu'un obstacle dépendant de l'etroitesse du bassin, retenant cette tête au-dessus du detroit (surtout si les contractions de l'utérus sont assez faible pour ne point presser fortement la tête sur l'ouverture de ce detroit), permettent au cordon ou à une main de glisser aupres et jusqu'au dessous d'elle."

5. The pelvis above the standard size.

I am not aware that this cause of prolapse of the funis has been noticed by any author except Madame Boivin †. It is probable that in such a pelvis the funis and head will descend together; but the same circumstances which cause this descent, also favour the speedy delivery of the child; and consequently such cases of prolapse are less dangerous than any other.

6. Presentation of the abdomen.

Deneux ‡, in his excellent memoir on prolapse of the funis, adduces this cause for its occurrence, and cites a case of Delamotte's in support of his opinion. The rationale is too evident to require observation.

7. Insertion of the placenta near the cervix.

This cause also is mentioned by Deneux, together with cases from Smellie and Mauriceau.

8. The funis being twined round some part of the fœtus.

This cause is adduced on the same authority as the two last, Deneux §. He is of opinion that presentations of that part of the child round which the cord is twisted, favour its descent by carrying it near the os uteri. It appears probable that when the funis surrounds the neck of the child it is, generally speaking, in little danger of prolapsing. But, even when it is round the neck, the risk of prolapse will depend upon the position of the head in relation to the brim of the pelvis at the time of the escape of the liquor amnii, the length of that portion of the funis which is not twined round the neck, and the situation of the placenta. Deneux * relates three cases in which the funis prolapsed, although twisted round the child's neck. In one of these, which occurred to Mauriceau, the funis and one hand presented, together with the head, before the rupture of the membranes. In the two others the cord was folded several times round the neck, and yet prolapsed. After a careful consideration of the foregoing circumstances, I think Mr. Roberton is not warranted in remarking †, "It is true, there is another cause which often helps to keep the funis from escaping before the end of labour: I allude to its becoming twined round the neck, body, and limbs of the child." Although I have not met with any recorded case in which the funis was found surrounding any other part except the neck, yet the frequent occurrence of its prolapse, conjointly with presentations of the extremities, probably depends upon its having been twined round the presenting part previously to the descent of this part into the pelvis. The funis becoming subsequently disengaged anterior to or at the time the membranes rupture, and its consequent descent by the side of the presenting part, may be easily accounted for by the manner in which the cord floats in the liquor amnii, and the extent of space which, in such presentations, is left unoccupied in the brim of the pelvis.

Treatment.—The object of the treatment, in cases of prolapse of the funis, being to save the life of the child, the first question to be decided is—How is the death of the child caused? It was formerly supposed that the escape of the cord proved fatal in consequence of its being placed in a lower temperature than that to which it had been accustomed. We constantly meet with cases in which the pulsation of the funis continues for 15 or 20 minutes after the birth of the child, and where the funis is more exposed to the influence of cold than in any case of prolapse. The truth of this view cannot, therefore, be admitted. Deneux ‡ is the only author who seems to have given a correct ac-

‡ Memoire, p. 19.

count of this subject. He states, that the death of the fœtus happens in two ways—

1st. In consequence of its blood not being able to pass to the placenta, where the change necessary to the existence of the fœtus is performed, it then dies of a kind of asphyxia. This appears to be produced by that state of the fœtal circulation, which is caused by such pressure on the cord as entirely interrupts the flow of blood both in the umbilical vein and arteries.

2d. The circulation in the umbilical vein being stopped by a degree of pressure inadequate to cause its cessation in the umbilical arteries, this continuation of the arterial circulation has the same effect upon the child which hæmorrhage would produce, its system being drained of blood, whilst the umbilical vein no longer supplies the loss thus occasioned.

This appears to me the best method of accounting for the pale and exsanguineous appearance of those children who are still-born in consequence of prolapse of the funis. The apoplectic condition of the placenta in these cases is also noticed by Deneux.

The treatment at present adopted consists in—

1. Leaving the case to nature.
2. Returning the funis, and keeping it within the uterus and above the presenting part, either by means of the hand or instruments, until its re-descent is prevented by the progress of the labour.
3. Turning the child.
4. The employment of the forceps.

Of these methods turning is the one most frequently in use at the present day; and the mortality is so much greater than in the cases reported by Mauriceau and Baudelocque *, as to lead to the conclusion, either that this operation has been adopted in cases to which it was inapplicable, or that it has been performed in an improper manner. For information on this part of the subject, Denman (Waller's edition), Mauriceau, Lachapelle, Deneux, and particularly Dr. F. Ramsbotham, may be consulted.

The remarks of the last, contained in his practical lecture on this subject †, fully coincide with the view I have been induced to take.

The length of time the cord has been down, even after the rupture of the membranes, is no guide for our practice, which should be entirely determined by the effect produced by the pressure suffered, as indicated by the state of its pulsations with reference to their regularity, force, and fulness. I think it will appear, on examination of those instances in which the child has been born alive after turning, that the cord had not begun to suffer materially from pressure previously to this plan having been adopted. In Mr. Roberton's successful case * the funis had been down from ten in the evening until five the following morning, and yet he found it pulsating in the vagina. I fully agree with Dr. F. Ramsbotham, that turning is not only uncalled for, but also injurious in all cases in which we should not have had recourse to it, in consequence of the other presenting part requiring its adoption, independent of the prolapsed funis. The cord will undergo more pressure, even in head presentations, during delivery by turning, than if the labour is left to the unaided natural efforts. In both instances compression of the funis must take place during the passage of the head. Where the head descends naturally, can this pressure be more injurious than when it descends, as must be the case after turning, in an unfavourable direction? But, even if it is admitted that the descent of the limbs and body of the child relax the soft parts, which will, therefore, cause less pressure than if the head passed first, yet against this must be balanced the compression of the funis, caused by the introduction of the hand in utero, which, even in the most favourable cases, and where the greatest caution is used, must be considerable, if the liquor amnii has already escaped. To this must be added the pressure the cord sustains from the time the abdomen of the child descends to the outlet of the pelvis until delivery is completed. How many cases of hand or arm presentation prove fatal to the child where no prolapse occurs, in consequence of this compression of the funis I have just described?

Where the funis can be returned by the hand, and its relapse prevented, this

* In 26 cases, in which Mauriceau brought down the feet, 20 of the children were born alive. In Baudelocque's practice, out of 36 cases 25 terminated safely, in all of which either turning or the forceps was the means employed.

† Medical Gazette, Sept. 20, 1834, p. 867.

* Medical Gazette, present vol. p. 560.

method is always to be adopted. But the employment of instruments for this purpose carries with it the objection, that scarcely any instrument will be adapted for all the cases that occur, and prolapse of the funis being a rare case, we have not the opportunity of using these instruments so often as to adapt them properly for their intended purposes.

When the funis cannot be returned with the hand, and when it is not suffering from compression in the manner already noticed, by far the safest practice to the child appears to me the leaving the case entirely to the natural efforts. It is impossible for the funis, under such circumstances, to suffer an amount of pressure so great as that which is caused by turning; and it appears probable that in all the successful cases in which turning was adopted, the child would have lived if the case had been left to nature.

When the head presents in such a manner as to prevent the artificial return of the cord, and the pulsation is feeble, intermittent, or irregular, particularly if it ceases during the pains, and when there is every probability of the labour being speedily terminated by the use of the forceps, either long or short, no time should be lost in having recourse to them.

From the foregoing remarks on the cause of the child's death, it may, I think, be collected that the compression, which entirely stops both the arterial and venous circulation of the funis, is much less injurious than that which affects the umbilical vein previously to the arteries. From the state of asphyxia produced by the former description of pressure, the child more frequently recovers than from the exhaustion occasioned by the latter. After extracting the head, and cautiously disengaging the funis, if twined round the neck, the delivery of the child should not be completed by traction. And if, when the child is entirely expelled, no pulsation can be felt in the region of the heart, inflation of the lungs and the other means for resuscitation must be had recourse to. If, however, the slightest pulsation of the heart can be felt, the child will revive much better by deferring for 15 or 20 minutes the ligature and division of the funis.

Before concluding the subject of treatment, I must refer to a method entirely different from any here noticed, but which, I believe, has never yet been adopted. It is recommended by A. C. Baudelocque, nephew of the celebrated author of that name, and noticed by Deneux. This plan consists in applying a ligature to the prolapsed funis so as to entirely stop its circulation and place the child in a state of asphyxia. The view which Deneux gives of the cause of the child's death in these cases appears to have suggested this treatment.

Such are the observations which a very cursory investigation of the subject of prolapse of the funis has led me to make. It would have been difficult to account for such an omission in the standard obstetric authors as is implied by Mr. Roberton's introduction to his paper on this important subject—viz., "The manner in which this distressing accident takes place has never, so far as I know, been adequately accounted for." Before we complain of the inadequacy of explanations it is at least our duty to become acquainted with those already given; and when we adopt methods of treatment recommended by others, it is equally imperative upon us to acknowledge the sources from which our information has been derived.

Manchester, Jan. 29, 1836.

STATISTICS AND MORTALITY OF HOSPITALS.

To the Editor of the Medical Gazette.

Sir,

At the conclusion of the Report of Cases treated by Dr. Macleod at St. George's Hospital, a few remarks are offered on the anomalous fact, published in the British Medical Almanack for 1836, that at that hospital the proportion the deaths bear to the patients treated is higher than in any other hospital in England. "In the British Medical Almanack for 1836, a table is given," says Dr. Macleod, "which professes to illustrate the comparative rates of mortality in the different hospitals of the metropolis. By the table in question it would appear that at St. Bartholomew's the rate is only 7·6 per cent., while at St. George's it is 10·6."

Dr. Macleod has here fallen into the error of former writers on the statistics of hospitals, in comparing the mortality of different institutions without taking into account the mean *time each patient remained in the house.* Now it is manifest, that although 10 persons in 1000 may die in *one year*, and 20 in *two years*, the rate of mortality would remain absolutely the same; *double* the proportion would die in double the time. It is the column of the table in the British Medical Almanack next to the one cited by Dr. Macleod, which shews the real comparative rate of mortality in the London hospitals. Only 7·6 per cent. of the patients admitted into St. Bartholomew's Hospital died; but this was in 34 *days;* and 10·6 per cent. of the patients admitted into St. George's died in 43 *days;* so that in the *same time*—36·5 days, assumed as unity—the rate of mortality in both hospitals was the same, 8·1 per cent.* This is explained in the Almanack, page 116.

Only the proportion of deaths to the admissions is generally given; but as the time of residence varies from 28 to 102 days, and as the difference is still greater in some European hospitals, a comparison of the mortality in such circumstances is absurd: unless the *time* is reduced to some unity, the relative intensity of mortality cannot possibly be compared. For the ordinary tables of mortality the u ity of time is one year; 36·5 days is here preferred, because it is near the average term of residence; and being the tenth of the year, can be readily compared with the ordinary tables by changing the decimal place: thus the average deaths for 36·5 days in the twenty-one (county) hospitals are 4·12 per cent.; for 365 days, 41·2 in 100 constantly living.

Besides this, in comparing the mortality of different hospitals, it is necessary to take into consideration all the data referred to by Dr. Macleod, and others mentioned in the Supplement to the Almanack; but it should be recollected that the mortality of an hospital is a very constant quantity, fluctuating but little from year to year, and must therefore depend on invariable causes.

In order to determine the mortality of hospitals it is absolutely necessary to know their mean annual population. According to the British Medical Almanack, this essential information, published by several county infirmaries, has hitherto been withheld by the governors of the London hospitals. In the article alluded to, it is stated that "*the average number of patients under treatment in the London hospitals is never published;* there is, consequently, no check on the expenditure—no valuable statistical information whatever officially furnished by these great and wealthy establishments."

As the Governors of St. George's Hospital have no motive for secrecy, the medical men have no doubt the power, and I hope the inclination, to have one page of such useful facts added to the next Annual Report. It will well supply the poetical exaggerations which disfigure these documents, generally written by clergymen, who, of course, know little of the matter. The following are some of the points which I think they may publish with advantage:—

1. The average number of patients in the house, and the number admitted each month. 2. The ages of the patients, living and dying, in decennial periods. 3. The number of cases that remain 10, 20, &c. days under treatment, and the average term of residence. 4. The causes of death, at least, if not the cases of disease, classified.

Dr. Macleod would enhance the value of his Report by stating the *ages* of the patients, which can never be overlooked; and the duration of each case in days, weeks, or months.

I remain, sir,
Your obedient servant,
William Farr.

8, Grafton-Street, Fitzroy Square,
Jan. 26, 1836.

The healing art is peculiarly the physics of living nature; and the process of cure an eternal experimenting in the regions of life.—Hufeland.

---

* The rate of mortality for the French hospitals is, I believe, correct; and for the hospitals of this metropolis the table in the Almanack appears to come very near the truth. Dr. Macleod states that the deaths at St. George's last year were 10 per cent. of the cases treated; for the previous years 10·6 per cent. is given in the Almanack. The mortality at St. Bartholomew's in 36·5 days is stated at 8·1 per cent.; and from an official report just published, I have calculated that the mortality for 36·5 days was during the last five years 8·0 per cent.

A CONCISE SUMMARY

OF THE

FACTS RELATING TO THE NATURE OF THE NERVOUS INFLUENCE.

By A. P. W. Philip, M.D. F.R.S. &c.

To the Editor of the Medical Gazette.

Sir,

It is necessary to preface the subject of the following paper by a few observations on electric tests; for writers, deceived by the name, speak of them as if they possessed a power equal to that of chemical tests.

There is, and from the laws of electricity we have reason to believe ever will be, an essential difference in the power of these tests. A correct chemical test will separate what we are in quest of from all substances with which it may be combined, and is therefore capable in all instances of detecting its presence, and consequently its absence also. This arises from there being but one counteracting power, that of affinity. If the affinity be stronger in the test than in any other substance, the effect of all other affinities is destroyed. We possess no such electric test, because here there may be other counteracting causes besides the power of affinity—opposing currents, for example.

Although electric tests, therefore, give evidence of the presence of electricity, we cannot by their means prove its absence, a fact with which we should not have been acquainted, were it not, under certain circumstances, possible to prove the presence of electricity without their aid; that is, the presence of electricity may, under certain circumstances, be proved, where it is not indicated by any of the properties generally admitted to be peculiar to it.

Suppose it were said, for example, that we cannot admit that electricity is the agent in the combination of oxygen and carbon, because there is no test by which its presence can be detected. The reply of Dr. Faraday, I conceive, would be, we cannot at present, whatever we may do hereafter, make the electricity employed in effecting this combination evident to any of our tests; but I consider its presence as a necessary inference, because I have adduced facts which prove either that electricity is the agent in such combinations, or that nature here deviates from the simplicity observed in all her other works. Either electricity is the agent in the combination in question, or there are two kinds of chemical affinity.

Under such circumstances can any other reply avail, except either disproving the facts, or pointing out the fallacy of the inference? What should we say of the reasoner who should tell us that the position is opposed to what he considers the best authorities, and give us, in refutation of it, dissertations on electricity, and on the properties of oxygen and carbon?

Of a similar nature with the foregoing is the position I have long maintained respecting the nature of the nervous functions, properly so called.

It appears from experiments repeated, as all my experiments were, in the presence of those capable of judging of the results, till no doubt remained in the mind of any of them, that the following are the nervous functions, properly so called:—

1. The excitement of the muscles of voluntary motion, in all their functions.
2. Of the muscles of involuntary motion, in some of their functions.
3. The maintenance of the processes on which animal temperature depends.
4. The formation of the various secreted fluids; and,
5. The processes of assimilation, by which the structure of our various organs is both effected and maintained*.

Of these functions the excitement of the muscles alone is the only one which may be supposed to be the effect of either a chemical or mechanical agent.

---

* Much confusion has arisen from confounding, in consequence of the organs of both classes of functions belonging to the brain and spinal marrow, the functions above enumerated, with the sensorial functions, to which, neither in their nature nor their properties, they bear the slightest analogy. (See my Inquiry into the Laws of the Vital Functions, part ii. chap. xi.) I have been asked if I suppose that electricity can feel or think.

Similar difficulties have arisen from another inaccuracy, if possible still more at variance with all just views of the nature of the animal economy, to which I had occasion to refer in a late discussion, namely, confounding the nervous influence with the principle of vitality, implying a confusion of ideas to which it would be difficult to adduce a parallel.

In all the healthy functions of life, however, in which the muscular power is employed, the stimulus which excites it, if we except the mere power of distention, appears to be of the former description. Even that which maintains the peristaltic motion of the alimentary canal, which, remotely depending on the stimulus of the food, may at first view be supposed to be the effect of a mechanical agent, appears to be wholly of a chemical nature. The muscular coat of the stomach is not duly excited unless the food has been converted into a healthy chyme, the formation of which it appears, from direct experiment, depends on the healthy state of the influence supplied by the brain and spinal marrow. In like manner the healthy action of the intestines can only be maintained when their healthy stimulant has been duly prepared by the chemical processes which take place in the duodenum, which also depend on the influence supplied by the brain and spinal marrow.

Many circumstances may prevent the electric nature of the functions above enumerated becoming evident to our tests. A more powerful affinity, counteracting currents, or other less evident causes, may for ever prevent electricity leaving the nerves to affect them; but the facts being admitted—and the experiments on which they rest have been too frequently repeated to admit of any doubt respecting their results, namely, that after the nervous influence is withdrawn, all its functions, even the most complicated not excepted, are as perfectly performed by voltaic electricity, as by that influence itself—I say, these results being admitted, it is a necessary inference that either the nervous functions, properly so called, are maintained by voltaic electricity, conveyed by the nerves; or there are two distinct principles of action, the one of which is capable of all the functions of the other; an inference not merely at variance with all we know of the operations of nature in other instances, but inconsistent with the principles of our knowledge, because the only knowledge we possess of any power is that of its properties, which are consequently the only means by which it can be distinguished.

Such are the facts and the very simple train of reasoning by which I was led more than twenty years ago to the inference that electricity is the agent in all the chemical processes of the living animal; a position strikingly illustrated by the late investigations of Dr. Faraday, from which it appears that to the agency of the same power we must refer *all* chemical processes.

In the various functions of the living animal we find many of its powers identical with those of inanimate nature. All admit that its mechanical powers are of the same nature with those of the world which surrounds it. And why? because we at once perceive in them the same properties. Now, on what principle can we doubt the same identity in its chemical powers, which rests on precisely the same basis? That in the one instance, from the simplicity of the phenomena, the truth is self-evident; and in the other, in consequence of their more complicated nature, requires the aid of experiment to make it apparent, constitutes no difference in the nature of the proof.

To those whose minds have been exercised on such subjects, the foregoing positions will, I believe, appear conclusive. My late discussion with Dr. Williams, however, has not been without its use, because it shows all that can be brought in opposition to them, by a man both of talents and information*.

I might have enumerated, among the facts tending to illustrate the nature of nervous influence, one in an essential respect the most important;—I mean the success of the practice founded on the view I was led to take of it.

In certain diseases of the brain and spinal marrow, in which the nervous influence fails, voltaic electricity has been found to afford important relief, and that of a kind which cannot in any degree be effected by other means†.

I am, sir,

Your obedient servant,

A. P. W. PHILIP.

Cavendish-square, Feb. 1836.

* Why Dr. Williams requested that certain extracts from Dr. Davy's papers, very important, doubtless, as relating to the peculiar property of the animals called electric, should be published as a post-script to our discussion, does not appear, since as far as they relate to it, they only confirm my statement respecting the results of Dr. Davy's experiments.

† My Inquiry into the Laws of the Vital Functions, Part III.

ANOMALOUS CASE OF LITHOTOMY.

POUCH CONNECTED WITH THE PROSTATE.

To the Editor of the Medical Gazette.

SIR,

IF you deem the accompanying case worthy of admission into your valuable periodical, its insertion will much oblige, sir,

Your most obedient servant,

JOHN LIZARS.

38, York Place, Edinburgh,
Jan. 22, 1836.

A surgeon attached to a large hospital has peculiar opportunities for improvement, and he fails of his duty if he either neglect them or conceal the useful rssults of his observation and experience. Success, though it flatters vanity, is at best an equivocal proof of merit, for it may happen to the rash and unskilful. Successful cases, in ordinary circumstances. when published, afford but little information; cowardice may be unwilling to divulge the unsuccessful, but these are for the most part our proper instructors; from these we learn whether nature or art is the more to be blamed for any untoward event; but whether successful or unsuccessful, those cases are invaluable which lead to the detection of such morbid deviations as would certainly occasion the death of a patient in the hands of a timid or irresolute operator. Of this last class is the following case:—

James Brown, a healthy-looking man, fifty-nine years of age, entered the hospital on the 29th December last, and presented the usual symptoms of stone in the urinary bladder, under which he had laboured during the last eight months. He had been in the hospital seven months ago, under the late Professor Turner, who sounded him, but detected no calculus. The day after his admission, he was carefully sounded, but no stone was felt; the bladder was rough and fasciculated. He was ordered warm baths, leeches to the region of the pubes, the mistura aquæ potassæ, the uva ursi, and a seton over the pubes. By these means all irritation having been subdued, he was again sounded, and a stone distinctly perceived. A dose of castor oil was administered, and on the following day the lateral operation was performed.

All the preliminary steps having been taken, and the existence of a calculus again ascertained, a large staff was inserted, which could not be made to pass the prostatic portion of the canal. A similar staff was next employed, which apparently entered the bladder, as its handle was loose and moveable. One of my colleagues held it over the pubes, whilst I commenced, and cut down to the membranous portion of the urethra. I then proceeded seemingly through the left lobe of the prostate gland, which was hard, cartilaginous, and studded with calcareous deposition. The left forefinger, which guided the lithotomy knife, seemed to enter the urinary bladder, and a little fluid, considered to be urine, flowed out; when I begged the staff to be withdrawn. I next inserted a pair of forceps; but instead of a calculus such as the sounding had led me to expect, I discovered nothing but calculi, varying in size from that of a millet seed to that of a pea. I now used the searcher, but was not more fortunate. My finger felt a pouch equal in magnitude to a urinary bladder, which contained numerous small calculi. One of my colleagues, at my request, introduced his finger, and the sensation communicated so nearly resembled that of a mucous membrane, that he suspected I had wounded the rectum, but convinced himself of the contrary by examining that viscus with the forefinger of his other hand. Another of my colleagues was also requested to examine, and he, with a scoop, removed some of the small calculi already mentioned.

I now inserted a catheter, which passed the entrance of this pouch, got into the bladder, and urine flowed out. The catheter was replaced by a staff, along which the knife was carried through the neck of the bladder, as there was no substance like prostate gland, and a stone of the size of a flattened plum was instantly extracted.

The first incisions into the pouch occupied about one minute: the second incision and extraction of the calculus about another minute. From fifteen to twenty minutes were spent in examining this pouch.

The patient has had no bad symptom; no case of lithotomy ever went on more favourably; and this is now the tenth day from the operation.

The anomalous pouch, which rendered this case so complex, seems to me to have been nothing more than the external fibrous capsule of the left lobe of the prostate gland gradually dilated until it became as large as the bladder itself.

Crosse, in his work on Urinary Calculus, p. 34, says, "Concretions in the prostate gland, commencing in its ducts, often at a distance from their urethral orifice, even at the very bottom of a duct, go on increasing until each duct is enlarged into a pouch, rendering an escape of the concretion into the urethra impossible; the narrow orifice by which the pouch commu-

nicates with the urethra becomes often closed in consequence of inflammation and effusion of lymph; the pouch is a secreting cavity which furnishes additional deposit; and as the secretions enlarge or multiply, the pouch enlarges in the direction where there is least resistance towards the lateral or posterior surface of the prostate gland."—See Plates ix. fig. 1; and xi. figs. 2 and 3.

Wilson, on the Urinary Organs, at p. 353, also observes, " I have met with a urinary calculus, larger than a common-sized olive, in a cavity of the prostate gland, where, from the orifice which first admitted it having contracted, or the size of the calculus having enlarged, the stone could not be pressed back into the urethra, and the whole of the prostate gland had been changed into a capsule surrounding it."

I possess a preparation in my museum with cysts exterior to the urinary bladder, one of which may hold from four to five ounces: these communicate with the bladder. Another preparation, where the right lobe of the prostate gland forms one capsule.

I confess freely that I was not prepared for the complication just described, nor am I ashamed to confess it, since no mention is made of such an anomaly in the writings of the most eminent surgeons, if we except Crosse and Wilson, from whose works I have quoted above, but which I had not seen.

ANALYSES AND NOTICES OF BOOKS.

" L'Auteur se tue à allonger ce que le lecteur se tue a abréger."—D'ALEMBERT.

A Practical Treatise on Midwifery, containing the Result of Sixteen Thousand Six Hundred and Fifty-four Births, occurring in the Dublin Lying-in Hospital, during a period of Seven years, commencing November 1826. By ROBERT COLLINS, M.D., late Master of the Institution.

THERE is not, we believe, any medical appointment in the united kingdom, which offers such advantages in respect to experience in midwifery, as the mastership of the Dublin Lying-in Hospital. Had the predecessors of Dr. Collins exercised a tenth part of his diligence, we should now be passing rich in facts of great value to practitioners. As it is, we hope the present volume will excite the industry and emulation of the author's successors.

The number of births mentioned in the title-page seems prodigious; but it appears to fall considerably short of the actual number of deliveries, the results of which Dr. Collins witnessed during a residence of ten years in the hospital both as assistant and master. We are told in the preface that these amounted to 24,119.

The main feature of the work is statistical: the tabular views with which it abounds—conveying a vast quantity of information in a space comparatively circumscribed—must render it to practical men highly important and necessary for the purposes of reference. But at the same time we should add that its interest is well kept up, the dryness of statistical detail being judiciously relieved by the illustrative cases interspersed. A few of these we are tempted to extract. The first two are examples of fatal hæmorrhage occurring previously to the expulsion of the placenta.

Uterine Hæmorrhage terminating fatally.

CASE 1.—Ann Douglas was admitted into hospital, March 19, in labour of her 13th child. She was not delivered for 20 hours, during the greater part of which time her pains were very severe; her child was born alive. Fifteen or twenty minutes after, suddenly, a dash of blood took place from the uterus, not however to any unusual extent; the afterbirth had not yet been thrown off. We were sent for, and in less than five minutes reached the ward; she was very much debilitated; her pulse only to be felt at intervals, her countenance ghastly, her body and extremities quite cold, accompanied with a state of great restlessness and anxiety. After having administered some stimulants, the hand was passed into the uterus, which was found considerably distended and filled with clotted blood; part of the placenta was adherent to the fundus; it was easily separated; the uterus acted well, expelling both hand and placenta into the vagina, from which they were slowly withdrawn. The patient from this time lost *no blood;* the uterus remained firmly contracted; the pulse continued weak and fluttering, often imperceptible, particularly after vomiting; which is not usually the case with patients reduced by hæmorrhage after delivery; as this occurrence seems rather to rouse the patient and improve the pulse. She gradually became more exhausted, her respiration difficult, the power of swallowing almost

lost, and frequently so restless, as to be with difficulty kept more than a minute or two in the same position; which in all cases of uterine hæmorrhage is one of the very worst symptoms.

From the time of the removal of the afterbirth, which was at 1 o'clock P.M., till 11 P.M. she was watched by myself and assistants, Drs. Nicholson and Darley, with the closest attention, and was liberally supplied with cordials; having in the course of those ten hours taken at intervals not less than two-thirds of a bottle of spirit, burned, and mixed with a little water and sugar, besides more than a pint of port wine. All possible means were used to restore heat to the body and extremities, as warm flannels, jars filled with boiling water, hot bricks, hot stupes, &c., but in vain; at length, finding our efforts to produce any rally ineffectual, we determined on trying the effect of transfusion.

Having heated Read's apparatus, by injecting through it water at the temperature of 90°, it was filled with blood which was made to flow through the pipe previous to its being inserted into the patient's vein, in order, as much as possible, to exclude all air from the instrument. The blood flowed copiously from a healthy young woman, whom we selected for the operation, and was easily thrown into the median vein of the patient's right arm. It did not seem to have any more marked effect than that of causing the woman to mutter indistinctly; the circulation was not improved, though we injected about ten ounces of blood. She expired in a few minutes after the operation.

This woman's death seemed to have been principally owing to her state of constitution previous to the coming on of labour; being in a very debilitated condition, both from the number of children, viz. 13, she had given birth to, as also her continued exposure to hardship; as the quantity of blood lost would not have materially affected any young person, but in her, the *sudden* loss gave the constitution a shock from which it had no power to rally.

We rather think the transfusion hastened her death, though we all dreaded a fatal termination before it was resorted to.

CASE 2.—Mary A. Courtney, aged 19, was delivered of her 1st child (living) on the 3d of December, after a labour of seven hours. In half an hour after hæmorrhage came on, which continuing, and the uterus not contracting satisfactorily, the hand was introduced, when the placenta was found morbidly adherent, and requiring much exertion for its removal. When this was accomplished, the uterus contracted pretty well, the hæmorrhage ceased, and her strength improved. An opiate was then given. In 30 minutes a draining of blood was observed, attended with sinking, jactitation, &c., and she died in half an hour, in spite of every possible exertion.

On examining the body, the uterus was found relaxed and exsanguineous, but in other respects healthy; there was nothing else observed worthy of notice.

Among the cases of ruptured uterus or vagina is the following very curious one, complicated with

Vagitus Uterinus.

Was 36 hours in labour with her second child, (her first born alive.) The pains were at no time severe, nor did the head descend so low into the pelvis as to cause the face to turn into the hollow of the sacrum. Her pulse was quick; she seemed anxious and restless; her strength began to fail, so much so, that her pulse faltered; her countenance became ghastly; extremities cold and livid, with vomiting. One hour previously she had no alarming symptom.

She was immediately delivered with the crotchet. The hand was then passed to ascertain the extent of the laceration, (as there could hardly be a doubt of its having occurred;) but none could be satisfactorily detected. She never rallied. She died in 17 hours.

On dissection, a laceration was found in extent about two inches, anteriorly and to the left side, running from the junction of the uterus and vagina, upwards in a longitudinal direction, and confined to the muscular substance of the uterus, the peritoneum remaining uninjured. There was a considerable effusion of blood between this and the muscular substance, near the lacerated part. There was also a quantity of bloody fluid in the cavity of the abdomen. The intestines were exceedingly vascular. The most extraordinary occurrence in this case was the *respiration* and *crying* of the *child in utero*: both of which were heard, as distinctly as possible, four hours before delivery, the latter at a distance of some yards from the couch on which the patient was lying. These facts were witnessed by myself and assistants, besides several of the pupils, both by stethoscopic examination, and otherwise. The head was, at this time, high in the pelvis; the soft parts partially dilated, and the waters but a short time discharged.

The cry was so distinct, that I imagined the child was merely placed under the bed-clothes. When called to witness this truly singular phenomenon, I little cre-

dited the truth of what I was told, and confess, had I not been present, I should have remained sceptical.

How forcibly should this fact prove the uncertainty of some of the tests most confided in, as indicative of the murder of new-born infants! It also affords the medical witness in such cases, a salutary caution, in addition to those so ably advanced by the learned Dr. William Hunter on this subject.

These must serve as specimens (we are sorry we have not room for more) of the kind of information which is copiously given in Dr. Collins's work.

Some of our readers may wish to be made acquainted with the heads of the principal subjects contained in the volume. These are, the different kinds of labours, beginning with the natural: under the head of complex, we have hæmorrhage cases, convulsions, rupture of the uterus or vagina, prolapse of the funis, twins, and triplets; observations on the general mortality of the Dublin Lying-in Hospital, (which, by the way, is under 1 in 100 annually); puerperal fever; still-born children; and remarks on the deaths of children dying in the hospital.

We are satisfied that this work only requires to be examined in order to be as highly esteemed as it deserves to be. The scientific practitioner will find in it a treasure of facts.

Leçons de Chimie appliquée à la Médecine pratique, et à la Médecine légale. Par M. Orfila. 1836. Dulau.

The quantity of useful information which this little volume contains, we are satisfied cannot be procured in any English work of twice or thrice its size. The student, therefore, of chemistry and legal medicine in particular, who cannot read French, must labour under a disadvantage: for here is a manual peculiarly adapted to his use, if he only possess the means of being familiarly acquainted with it. We are sorry to entertain a supposition of the inability of *any* of our students to avail themselves of the valuable elementary works which issue from the presses of France and Germany: but we fear, notwithstanding the oft-repeated theme of our lecturers and writers on medical education, that the study of foreign languages is greatly neglected by the mass of English students. The loss we hold to be a serious one, and one which, we doubt not, many of our young friends will in after-life have to regret.

It is of course only a condensed abstract of Orfila's lectures which we have here; but the work of condensation and abridgment is well performed; and the result is what we consider to be an excellent little production, most useful to have at hand for immediate reference. It notices all the recent discoveries in chemistry, with their applications to practical medicine and toxicology.

MEDICAL GAZETTE.

Saturday, February 6, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

Cicero.

A WORD TO STUDENTS ON THE RECENT MEETING.

The remarks on the Court of Examiners at Apothecaries' Hall which we made in our last number but one, as well as our open, reiterated, and continued disapprobation of the latest and most harassing edition of their "Regulations," must have convinced every impartial person that we are as ready to express censure where we think it due, as we are steady in refusing to join the hue and cry of the demagogue, who finds fault alike where there is reason to do so and where there is not. Agitate, agitate, is his motto; and to convert this agitation to his own proper gain, is the secret but powerful spring, which regulates every thought, and word, and action. To those not blinded by passion the selfish and interested motives which led to the instigation of the late meeting of medical students appear naked and revolting. A candidate is rejected at Apothecaries' Hall, and without any inquiry—without the possibility of knowing any thing about his examination,

except from the young gentleman himself—the case is at once assumed as an instance of injustice and oppression; the parties are taxed not only with "vulgarity, rudeness, cruelty, insolence, heartlessness, grossness, and brutality," (and the manner in which those epithets are used shows how foreign to the writer's nature is the coarseness he denounces), but the Examiner, is charged with "ignorance,"—an ignorance the extent of which, we are informed, was proved by the "errors he committed" in the course of the examination. Now, setting altogether aside the *ex parte* statement on which this assertion is grounded, we put it to the common sense of any one (except the writer of the paragraph in question) if it be probable that a gentleman accustomed for years to the routine business of examination — one who spends every Thursday evening of his life in asking certain sets of questions, should not know whether the answers given to them be right or wrong? Such an Examiner might be rude, or petulant, or overbearing—and we fear there has too often been grounds for such charge—but when he is accused of *ignorance*, every unprejudiced person feels at once that the imputation results purely from the spirit of party. We have not appealed to the individual by whom this allegation was made; and simply for this reason, that he knows its falsehood as well as we do: but then he is aware that bold assertions, when in accordance with the feelings, are not always very scrupulously weighed. Young men are very naturally anxious and excitable on the subject of their examinations; they listen with eagerness to any imputation on the fairness or competency of their Examiners; and naturally indignant at the idea of injustice, easily become the tools of one who has long studied their sentiments and wishes, and even their prejudices, in order to turn them to his individual ends.

From this dishonest play upon their excited feelings, this unworthy tampering with their hopes and fears, we turn with indignation, and make our appeal to their judgment, confident in the strong reaction which has already been manifested, and strong in the consciousness of having no personal antipathies—no private interests—no political considerations—to mislead us. We tell the students fairly and boldly, but without disrespect or unkindness, that they have fallen into a great error—not in seeking the redress of any grievances of which they have to complain—but in their mode of doing so. From the moment that the medico-political adventurer of Finsbury was allowed to contaminate the proceedings by his interference, all moral weight which their resolutions might otherwise have had, was at once annihilated.

It is not fit that men devoted to scientific pursuits, and to a learned profession—a profession of gentlemen—should so underrate themselves as not to feel, and instinctively to shrink from, the moral contamination of such unwholesome presence. Neither ought the meeting to have been weakened by the attendance, much less ought it to have been presided over by one so palpably interested (even interested in a pecuniary point of view) as the private teacher of the rejected candidate. Such a petition as that which has been prepared—one so got up, and bearing such a signature, does not, and need not, give the Society of Apothecaries one moment's uneasiness. To neutralize it, no more is necessary than to put any member of the House of Commons in possession of the facts, and to get him to state in his place in parliament, that the meeting was convened under the patronage of

Mr. Wakley, and that the petition is signed by one person only — the "grinder" of the rejected candidate. This part of the affair was, indeed, a great mistake on the part of the students, and showed a plentiful lack of wit, or marvellous vanity, on the part of the Chairman.

Another point on which the students erred grievously, was assuming, on such imperfect evidence, that the rejected candidate was not deficient. The Editor of the Lancet, indeed, says, it was known "to the lecturer" that he was fully qualified; but we have heard a very different account, and dare him to the proof. It is easy to bluster about another examination, *because it is known that by the Act of Parliament this cannot be complied with*, and that six months must necessarily elapse before the party *can* receive a second trial. But we ask this—will the rejected candidate demand that the examination he has already undergone be published? We strongly suspect that he will not; but we are, at the same time, confident that after his open challenge, which, however, as we have said, the law renders but a mere bravado, the Court of Examiners are bound in self-defence to make known the grounds of his rejection.

It will thus be seen that, judging from all the information we have been able to collect, we entirely repudiate the idea of the Examiners being "ignorant," or the gentleman whom they rejected "fully qualified;" and that we utterly disapprove of the students meeting under the auspices they did. But this does not alter in any degree—no, not one single tittle—our yet unanswered allegation, that pupils, in their intercourse with the officers of the Worshipful Society, have sometimes been treated as if they were not gentlemen,—have met with rudeness at the very onset, ere yet their studies in London could be said to have commenced,—and that when they have gone up for examination, if found unprepared, they have sometimes had the bitterness of rejection increased by its being accompanied by censure—censure which, at such a moment, is unfeeling, even if deserved. This is not to be borne, and must be amended; it is a serious evil to the students in medicine, and it constitutes the triumph of the agitator, to whom it affords a foundation to build on; and a goodly superstructure of misrepresentation he has contrived to rear upon it!

But "coming events cast a shadow before," and, even as we write, the rumour of approaching change is whispered around us. What powers will be conferred on the medical department of the New University?—will the privilege be limited merely to conferring degrees in physic, or will it extend to the granting of licenses to practise as apothecaries?—will grades heretofore unknown in this country be established?—are we to have a lower qualification for Licentiates in medicine and in surgery, and a higher standard for Doctors in both these departments? Greater wonders than these have come to pass; but as yet they are in the womb of time, and the hour of delivery is not come.

PUFF PETITION

IN BEHALF OF THE PROFESSION.

A Mr. Baker, of 1, Dorchester Place, Hoxton, is taking a prodigious deal of pains to advertise himself in connexion with a petition to Parliament for procuring remuneration for medical witnesses attending coroners' inquests. We know nothing of this gentleman save what we gather from his productions. One of these, in the shape of a handbill, we thought it right to introduce to the notice of our readers, with remarks, some months since; and a richer specimen of the mode of customer-catching adopted in certain parts of the town, it was generally admitted, could not easily

be displayed. The petition now before us is so much a counterpart to the bill, that we are tempted to make an extract or two.

"*To the Honourable the House of Commons, &c.—The Petition of James Baker, &c. on behalf of himself and the Profession of which he is a Member,*

"Sheweth,

"That your petitioner having been called, on the 22d day of July, 1834, *to attend* Elizabeth Headhouse, whose body was lying in a long lonely road, *bounded the whole length* by a field of considerable extent on the one side, and the Regent's Canal on the other, at some distance from your petitioner's residence, at the hour of two o'clock in the morning, and in consequence of what your petitioner then saw and *ascertained of a suspicious character*, and *a man* who was taken near the place, having been detained in custody under suspicion of being criminally concerned in her death, your petitioner performed a post-mortem examination, and attended to give evidence at the inquest, on the 24th, when the investigation was adjourned, as the jury requested the contents of the stomach to be analyzed before they returned their verdict; and an application was made to your petitioner for that purpose, but your petitioner declined *the tedious and unpleasant duty* without a special order," &c.

So much for the opening of the case, which, we confess, we had to read more than once in order to form some conjecture of what Mr. Baker might probably mean. The length and complexity of the sentence (for the whole of which we have not room), we rather fear, will puzzle parliament not a little. But we pass on to more beauties:—

"That your petitioner, in compliance with such judicial injunction, and with a sincere desire to promote justice, in the presence of the coroner and jury *took* the contents of the stomach *for analyzation*, and the inquest was adjourned till the 28th, to give your petitioner time for the necessary processes and tests *in severance of the abstract specific matter connected with such a case* (!), which your petitioner with assiduity and scrupulous minuteness performed, and *attended thereon* at the adjournment."

And what was the modest demand made by our lover of justice "for the *severance* of the *abstract specific matter connected with such a case?*" Hear him once more:—

"That your petitioner, after the inquest had terminated, applied for the moderate sum of *three guineas* for his services, *although ten guineas is the customary fee.*"

We wish Mr. Baker would favour us, or "the profession of which he is a member," with his notes of this famous *analyzation*, which he considers cheap at *three* guineas, and for the like of which, he says, the customary fee is *ten*. We have no doubt that his publishing it would give him additional claims to attention.

But our petitioner is not selfish; he draws up a short prayer separately, for the profession in general, an echo of his own, and humbly asking Parliament—for what? for "*a clear and certain remedy!*"—an odd request, as it strikes us, for a medical petition to conclude with: if the business-members only cast their eyes to the foot of the document for the prayer, they must think we want reform in good earnest, when we ask of them for a panacea—some universal specific—"a clear and certain remedy."

To crown the matter, we are informed by Mr. Baker that the said "petition LAYS for signature" in several places which he mentions. Sir Boyle Roach once asked how he could be in two places at the same time—barring he was a little bird? But Mr. Baker's petition far surpasses Sir Boyle's bird; it can not only be in half a dozen places at once, but *lay* also in the said localities.

And this Mr. J. Baker is the person who takes up the cause of the profession single-handed, and attempts to thrust himself into publicity at their expense! We have not for a long time met with a better example of the adage, that "Fools rush in," &c. The cause, we are most ready to admit, is a good one; it is just and expedient that medical men should be remunerated when called upon to give their professional assistance in forwarding the administration of the laws; but many a good cause is lost by the interference of bungling and vain blockheads. In the present instance, besides, the meddling of such an officious party is wholly unnecessary: the County Coroner's Bill was lost in the last two sessions of Parliament only

in consequence of some trifling impediment; *the clause for fixing the remuneration of medical witnesses at 2l. or 3l. was actually carried*, and it only remains to bring it forward again this session, with some slight technical alterations, in order that it may become the law of the land.

We must therefore particularly request Mr. James Baker, of 1, Dorchester Place, Hoxton, to keep himself quiet; or if he needs occupation, to go to some respectable evening school in his neighbourhood, where he may acquire the rudiments of English grammar.

WORKING OF THE CONCOURS.

It is nothing new to find that what is plausible in theory, sometimes halts lamentably in practice. This appears to be remarkably the case with the concours, which some wiseacres are anxious to introduce among us. In France, where it has been long adopted, the experience of many years has been insufficient to contrive any plan by which the elections by *concours* may be freed from the charges of intrigue and favoritism; thus each vacancy which takes place affords occasion for a renewal of the most violent tirades against all concerned, coupled with the most unhesitating accusations of corruption and dishonesty. Nothing can exceed the virulence with which M. Orfila, as Dean of the Faculty, is at this moment assailed; and whether with justice or not, in either case the insufficiency of the present system to satisfy the public mind, is equally and lamentably proved. For heaven's sake let our contemporaries who are affected with this Gallo-mania look at what is going on in the French capital, and say if the *concours* be calculated to allay party spirit.

EGYPTIAN STUDENTS OF MEDICINE.

THEIR RETURN HOME.

The young men who were brought from Egypt by Clot-Bey, and placed at the medical school in Paris, for the purpose of pursuing their medical studies, have recently been sent back to their native country. They remained in France three years and a half, and are said to have made excellent progress in their studies. It was intended originally that they should remain a year longer, so as to have taken their degrees in medicine, but the circumstance of many medical men in Cairo and Alexandria having fallen victims to the plague during its irruption, has induced the government to require the immediate return of those who had been sent to Paris; and we cannot but hope that the enlightened views which they have there acquired will lead to important improvements in Egypt, now so rapidly emerging from the darkness which has hung over it for ages.

ORIGINAL PAPERS IN DIFFERENT JOURNALS.

The British and Foreign Medical Review, recently published, contains a "List of original papers published in the British journals during the last quarter." By this list, which is exclusive of lectures and hospital reports, the number of papers contained in each journal respectively is as follows:

Edinburgh Medical and Surgical Journal—*eight*.

Dublin Medical Journal—*fourteen*. (This, however, embraces two numbers of the journal).

The Lancet—*fourteen*.

The Medical Gazette—Forty-two.

Reckoning the number of persons by whom those communications have been made to the two latter, the account stands thus:

Contributors to the Lancet during the last quarter—*eleven*.

Contributors to the Medical Gazette during the last quarter—*thirty-seven*.

THE LATE DR. WM. TURTON.

In the death of Dr. Turton, the profession has to lament the loss of one of its most learned and estimable members. In the various departments of natural science (particularly in botany and conchology) we believe he had few or no rivals. The latter years of his life were spent at Bideford, Devon, where he died rather suddenly, on the 28th of December, 1835, in the 73d year of his age.

Dr. Turton was born at Tockington, in Gloucestershire, near Bristol: he had two brothers, both in the law (to which pro-

fession his father also belonged), and three sisters, the youngest of whom became the wife of the celebrated Lackington, the bookseller. Where the Doctor received his medical education we have not learned, but he graduated at Oxford, being a member of Oriel College. When Dr. Jenner's discovery of vaccination began to attract the notice of the profession, Dr. Turton was among the first to appreciate its advantages, and to proclaim the benefits to be derived from its general adoption. He was certainly, as we are informed, the first who introduced the practice of vaccination into Wales. This was in the year 1799; he lived at the time in Swansea; and it is worth adding, that the first subject on whom he tried the vaccine lymph was his own daughter, an infant, who was afterwards baptized by the name of Vaccina, in memory of the circumstance.

The disease of which the Doctor died, is said to have been a spasmodic affection of the heart. He was out, and perfectly well, on Saturday: on Sunday he complained a little, and died in the course of the night.

He was a man of mild and gentle manners, and of very retiring habits. He has left four children. Mrs. Turton, who also survives him, was the daughter of the Rev. Denny Cole, of Pettistree Hall, in Suffolk.

Among the works by which the name of Dr. Turton is best known to the public, are 1. A Medical Glossary, in which the words used in the various branches of medicine are deduced from their original languages, 4to. 2. Observations on Consumption, Scrofula, and some other forms of disease. 3. A General System of Nature; comprehending Animals, Vegetables, and Minerals, 7 vols. 4. An Edition of Goldsmith's Animated Nature, with Notes and Additions, 6 vols. 5. The British Fauna. 6. The Bivalve Shells of the British Islands; with 20 coloured plates. 7. A Manual of the Fresh and Salt Water Shells of the British Islands, arranged according to the modern systems of classification, and described from perfect specimens in the author's cabinet, with coloured plates of each species.

No fruit thrives without the dew of heaven; and this is not only the case with earthly fruits, but with those of a spiritual nature.—Hufeland.

The bitter principle is only a product of organic chemistry — that is, of life: thus without life there is no bitterness, morally or physically.—Hufeland.

LECTURES ON THE DISEASES OF THE NERVOUS SYSTEM.

By M. Andral.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

HÆMORRHAGE OF THE NERVOUS CENTRES.

(*Affections of the Senses and Intellect, concluded from page* 700.)

When the sight of one eye is abolished, on which side does this take place? In one set of cases of this affection, the vision was lost on the same side as that on which the paralysis and loss of sensibility existed; while in another set of cases, the loss of vision was on the side opposite to the above; and the phenomena may be explained by a knowledge of the situation in which the effusion takes place, and of the influence which this is capable of exciting on the roots of the optic nerves, which, as is well known, are very numerous; some of them mingling without crossing, others actually crossing, and yet others running direct to their destination; so that according as the hæmorrhage has implicated this or that set of roots, the loss of vision will be direct or crossing.

Is it possible, when the sight is abolished, to determine *à priori* whether the extravasation be in the optic thalami, or tubercula quadrigemina? Theory replies in the affirmative. There are cases, certainly, in which vision is abolished, and yet the tubercula quadrigemina are intact. According to M. Serres, in order to produce blindness, it is necessary that the lesion be found in the commissure of the optic thalami; while the upper part of these ganglia may be implicated without this effect being produced. But blindness has been met with in cases where the hæmorrhage had occurred far from the optic thalami—in the cerebellum, for example, as, indeed, I have already stated.

In cases of extensive hæmorrhage, the pupil is dilated in proportion to the affection of the sight. The same considerations apply to the other senses: hearing may be abolished if the extravasation be very great; but it is only modified where the cerebral lesion is less considerable. The senses, too, may be affected in different ways, in certain lesions of the fifth pair of nerves, as I formerly mentioned in the *resumé* given in my first lecture.

The changes of sensibility, with their different forms, observed in hæmorrhage of the hemispheres, are also found in hæmorrhage of the mesocephalon, the symptoms of which are very speedily fatal. We have coma, and much depravation of sensibility. When the spinal cord is affected with hæmorrhage at its central part, there is loss of sensibility to a greater or less extent.

INTELLECT.

Let us adopt, with respect to the disturbances of intellect connected with cerebral hæmorrhage, the same divisions we have laid down in regard to the other functions. In the majority of cases, before the supervention of the apoplexy, it only affords negative symptoms. Nevertheless, in a certain number of cases, there is a perceptible sluggishness of the intellect for a longer or shorter time before the attack; labour becomes irksome, and there is a dulness which always leads to a preference of intellectual repose; this is attended by a tendency to sleep. In others, again, we remark a singular excitability, a constant desire of motion and change of place. Instead of having the intellect dull, as in the preceding cases, it is here morbidly active. In yet others, there are hallucinations resulting from an excited state of various senses—hallucinations, by the way, which are occasionally very remarkable, and to which I shall take an opportunity of again returning in detail.

Disturbances of the Intellect occurring at the moment of the Hæmorrhage.

1. It has been too often said that hæmorrhage of the nervous centres is always accompanied by loss of intellect. This is very far from being constant; and, indeed, the intellect may remain quite undisturbed.

2. In certain cases the intellect is diminished, without being abolished.

3. It may be entirely lost.

The cause of these differences is to be sought, I think, in the intensity of the disease rather than in its seat. Wherever the lesion is of small extent, the intellect remains entire; but if the lesion be considerable, there is some modification of the manner in which the brain elaborates thought. It has been a question whether this also holds good when the lesion exists in other parts than the brain itself? The answer is afforded by a certain number of cases of hæmorrhage of the cerebellum, in which the intellect was abolished. The thirty-two cases analysed in a previous lecture go far to show this, whether it be that this organ participates in some manner in the intellectual functions, or that its disease reacts sympathetically on the brain.

With respect to the mesocephalon, as all the cases of hæmorrhage of this part which have been observed have been very severe, and always accompanied by coma, so has intellect always been abolished.

In hæmorrhage of the spinal marrow the intellect is retained, and it is chiefly by lesions of sense and motion that the sympathetic symptoms of this malady are manifested. The exceptions to this, which are sometimes met with, are to be explained by the reaction of the spinal disease upon the brain; for every thing is connected in the animal economy, and not a molecule can be deranged in one part without influencing the others more or less. M. Fabre, in his thesis, has quoted the case of a patient in whom the anterior pyramids alone were the seat of hæmorrhage, without the slightest trace of extravasation elsewhere; and this very limited lesion was coincident with a complete abolition of intellect: in fact, the apoplexy had been as profound as it is seen to be in the most extensive hæmorrhage of the hemispheres of the brain.

Let us now resume the general history of hæmorrhage of the nervous centres. The hæmorrhage once completed, the blood no longer continuing to flow, either death must take place, or reabsorption be commenced.

If the hæmorrhage be great, the intellect is abolished, and this abolition remains permanent; coma is present, and this becomes more and more deep. If the hæmorrhage has been less active and more limited, the individual becomes roused, and resumes that communication with the external world which the hæmorrhagic attack had, as it were, cut off: he recovers a portion of his intelligence. In some cases, indeed, the intelligence regains all its power;—for example, men of letters have been known, after an apoplectic seizure, to return to their accustomed and cherished pursuits, without their works affording any evidence of their having suffered so terrible a malady as cerebral hæmorrhage: more frequently, however, there remain certain disorders, although they may not perhaps manifest themselves in ordinary intercourse; but if the patient attempt any thing requiring great or continued mental exertion, his inability to accomplish it becomes manifest; his brain is no longer what it formerly was, and can no longer act as before the attack; and this loss of mental power subsequent to the attack is sometimes conspicuous in those who did not shew it at the onset; it steals on progressively, by a gradually increasing weakness of the mind.

Others are still more unfortunate than the preceding, not being capable of even the business of ordinary life, and thus a state of childishness and imbecility succeeds to the attack, and always goes on increasing. Under such circumstances, if the patient be plagued, or employed about any thing which he dislikes, he very readily weeps, without the least appeal having been made to his sensibility. In others the diminution of the intellectual powers is not progressive, but takes place suddenly, the individual falling into a state of acute mental alienation. Cases of this kind are rare, but I am acquainted with some such. Febrile delirium comes on in others; and this state, which is distinct from insanity, shows that there exists a complication of the case with inflammation of the brain or its membranes. But the intellect may be affected not merely in the mass; the numerous faculties of which it is composed may be separately diseased. Thus it is not uncommon to meet with hemiplegic patients who exhibit their usual manner in conversation, and yet, if you ask them what they were about the day before, they cannot tell you: their imagination is entire, but their memory is gone. Sometimes it is not the *whole* memory which gives way, but only the recollection of particular things: thus sometimes they are only puzzled in finding substantives to express their ideas, the memory of which may be totally abolished. This, however, is a subject to which I at present allude only *en passant*, as I shall have occasion to allude to it hereafter.

We have seen that many persons lose the power of articulation, and this may depend upon modifications of the organs of speech themselves—as of the tongue, for example; but language is not formed by the tongue alone—it results from a special faculty of the brain; and man alone can speak, because he alone has such cerebral organization as is compatible with speech. Accordingly we may have, and actually do frequently meet with, cases in which the individual becomes dumb without the movements of the tongue having undergone the slightest modification, but depending upon a lesion in that part of the brain which regulates the co-ordination of ideas on which articulate language depends. We see, in proportion as we advance, that the functional lesions are insulated; a circumstance which proves the existence of a special seat for each in the brain: but I do not mean, by this, to say that the seat in question is known to us. On this point there is nothing but confusion and contradiction in science, and, as an example, let us take speech, and examine the facts which have served as the grounds of this attempt at localization.

M. Bouillaud, who has paid much attention to this subject, has inferred from his cases that the power of speech becomes modified when a lesion takes place in the anterior lobes of the brain. Now, on examining this doctrine, I propose to appeal to facts, just as I did in tracing the connexion between lesions of particular parts and paralysis either of the upper or lower extremities.

It appears, then, that in thirty-seven cases in which there was lesion of the anterior lobes, there was complete abolition of speech in twenty-one, while the faculty was retained in sixteen. It thus appears that lesion of the anterior lobes does not necessarily cause loss of speech; neither does it prove that they are not the seat of the function, because, in the sixteen where speech was retained, the lesion may have been slight. It would be requisite to ascertain how the speech is influenced where, the anterior lobes being intact, the posterior and middle lobes are diseased. In seven cases there was lesion of the posterior lobes, the anterior being unaffected; the power of speech was abolished. In seven other cases also speech was lost, although the anterior lobes were healthy, the lesion being in the middle and posterior lobes. An old woman was admitted into La Pitié, who had entirely lost the power of speech during two years; the movements of the tongue were quite free. She died, and I examined her with the utmost care. There was a small portion of softening in the centre of each hemisphere, on a level with, but exterior to, the interval which separates the optic thalami from the corpora striata, consequently it was in the middle lobe. There was absolutely nothing else. This case is of great importance in reference to the present question, for when the disease suddenly proves fatal, it may be said that if the anterior lobe was not actually implicated, there was, at least, a reaction upon it; but here this supposed reaction will not apply, because the case was entirely chronic. M. Recamier was led to suppose that the portion of the brain which presided over speech was the middle part of the centrum ovale of Vieussens; and other authors have assigned to it other seats: M. Serres, for example, has placed it in the corpora striata, M. Foville in the cornu ammonis, &c. These are evidently conclusions drawn prematurely from too limited a number of cases; for not only may speech be abolished with cerebral lesions the most different as to their seat, but the loss of speech may be coincident with complete integrity of the whole brain. M. Lal-

lemand has quoted a case where the lesion did not exist in the brain at all, but only in the cerebellum; the hemisphere of the brain did not present the slightest alteration, and yet the faculty of speech was abolished.

From all I have said, it follows, that we can only establish one solitary fact—namely, that the loss of speech is a frequent consequence of cerebral hæmorrhage; and although there must be some difference between the cases where the faculty is lost, and where it is retained, yet in what that something consists is yet to be discovered.

M. Cruveilhier, some time ago, saw a case in which the loss of speech coincided with a lesion of the tuber annulare, near the medulla oblongata; but this part of the question I shall have occasion to examine more particularly in the sequel.

Having now pointed out the modifications which the life of relation undergoes from hæmorrhage of the nervous centres, we shall next proceed to examine the influence which the same cause produces upon the actions of nutritive life.

COURT OF EXAMINERS OF THE APOTHECARIES' SOCIETY.

To the Editor of the Medical Gazette.

Sir,

The last paragraph of the very commendable and temperate resolutions passed at a meeting of the students at St. Thomas's Hospital (p. 704), requires some explanation. The words employed are—"That this meeting also strongly disapproves the principle of self-election and irresponsibility."

If by this it be only intended to express an opinion upon the principle, no objection can be made to the resolution: but it seems to imply something more—namely, that the Court of Examiners is a self-elected and irresponsible body. If the students at St. Thomas's have been led to believe this, they are misinformed.

When James I., in the year 1617, separated the Apothecaries from the Company of Grocers, with whom they had been incongruously associated, and incorporated these practitioners of medicine by the title of the *Society of Apothecaries*, he placed the executive power of the Society in the Master, Wardens, and Court of Assistants, amounting together to twenty-four members: and when, in 1815, the first Medical Reform Act was passed, commonly called the Apothecaries' Act, the power of electing twelve persons, duly qualified to constitute the Court of Examiners, was intrusted to this executive body (the Master, Wardens, and Court of Assistants), who are authorized and required to elect annually twelve members to compose the Court of Examiners: it is clear, therefore, that this is not a self elected court.

Neither is the Court of Examiners an irresponsible body; on the contrary, they are answerable for their conduct to the Court of Assistants: and if any well-grounded complaint was made to the Master, Wardens, and Court of Assistants, of any misconduct on the part of a member of the Court of Examiners, an investigation of such alleged misconduct would be assiduously entered into; and if good and sufficient proof was given of such misconduct, or if it could be shown that any member had been guilty of not "faithfully, impartially, and honestly, according to the best of his skill and knowledge, executing the trust reposed in him as an Examiner, without favour, affection, prejudice, or malice," agreeably to the oath which he solemnly swears before he is admitted to the office, he would be immediately suspended from his seat in the Court, and assuredly would not be re-elected.

Since the election of the first twelve Examiners, when the Court was established in 1815, twenty-one other persons have at various times been appointed members by the Court of Assistants, and in no one instance has an attempt been made to show that any person has been elected on the Court who was not a man of honour, respectability, and professional science.

A Friend to Medical Students.

Jan. 31, 1836.

MEDICAL ATTENDANCE AT CORONERS' INQUESTS.

PETITION FROM THE PRACTITIONERS OF BERKSHIRE.

To the Editor of the Medical Gazette.

Sir,

I take the earliest opportunity to inform you that at a Committee Meeting of the Berkshire Medical Association, holden *this day*, at the Reading Dispensary, the following petition was prepared for presentation to the House of Commons. I am directed to request that Robert Palmer, Esq. will do us the honour to present it, and also to furnish a copy to all the members in the county, with an earnest solicitation for their support.

I have the honour to be, sir,
Your obedient servant,
George May.

Reading, Feb. 2, 1836.

To the Honourable the Commons, &c.

The Petition of the undersigned practitioners, in Reading and its vicinity, and in other towns and villages in the county of Berks, humbly sheweth,

That your petitioners have been at all times willing to further the due administration of justice in their attendance on coroners' inquests.

That the duties which thus devolve on your petitioners are highly important and responsible; requiring the possession of extensive knowledge, and the devotion of much time and anxious labour.

That your petitioners are advised and believe that the present state of the law has not provided a remuneration for their services.

That your petitioners respectfully approach your honourable house, in the temperate but earnest language of complaint and remonstrance, humbly beseeching you to remedy this injustice, and to enact such equitable remuneration as to your wisdom may seem meet.

And your petitioners will ever pray, &c.

COLLEGE OF SURGEONS.

LIST OF GENTLEMEN WHO RECEIVED DIPLOMAS IN JANUARY.

James Dixon, London.
James Carter, Witham, Essex.
John Pyle, Nether Wallop, Hants.
Horatio Weston, London.
Thomas Norris, Wigan.

Except the 30th ult., and the 1st instant, generally cloudy, with frequent showers of rain.

Rain fallen, 1 inch, and ·025 of an inch.

CHARLES HENRY ADAMS.

NOTICE.

MR. MEADE.—We have received a coarse and vulgarly abusive letter from this gentleman, apparently designed for publication: any temperate reclamation we should insert, but not an impertinent tirade like that before us. We commend Mr. M. to his friend's journal—the Lancet—for the pages of which his composition is exactly suited.

WILSON & SON, Printers, 57, Skinner-St. London.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

By Jon. Pereira, Esq., F.L.S.

Lecture XX.

ON AMMONIA AND ITS PHARMACEUTICAL COMPOUNDS.

The next substance obtained by the decomposition of animal matters to which I propose directing your attention is *Ammonia.*

History.—The term *sal ammoniacus* is met with in the writings of Dioscorides and Pliny, but some of our most learned authorities are of opinion that it refers to common salt. The erudite Beckmann says—"I am convinced that the *sal ammoniacus* of the ancients was rock salt, and not our *sal ammoniac.*" I think it is not unlikely that the two substances may have been confounded under the same name. The first distinct traces of the salt which now bears this appellation, are to be met with in the writings of Geber, an Arabian, who lived during the eighth century, but it seems to have been quite common in his time. Ammonia, in its gaseous and uncombined state, was first obtained by Dr. Priestley in 1773.

Synonymes and etymology.—The substance (whatever it may be) which the ancients termed sal ammoniacus, is, by some, stated to have derived its name from *Ammonia*, a district of Libya, where the oracle of Jupiter Ammon was situated; or rather, according to Pliny, "quia sub arenis inveniatur,"—αμμος, signifying sand. Few substances have had a greater number of synonymes than ammonia, some referring to the sources whence it may be derived—for example, the terms *spirit of urine, spirit of sal ammoniac, spirit of hartshorn*, and *bone spirit*: some founded on its properties, as *volatile alkali* or *alkaline air*: others, lastly, referring to its composition, of which *azoturetted hydrogen* is an instance.

Native state.—It is found in both kingdoms of nature—the inorganic and organic. Muriate and sulphate of ammonia (the latter called by mineralogists *mascagnine*) are met with native in the neighbourhood of volcanoes. Ammonia-alum, found in Bohemia, is likewise another native ammoniacal salt. Chevallier has recognized ammonia in many native oxides of iron, and in the chalybeate waters of Passy. It is one of the bases found in urine, where it exists in combination with phosphoric and muriatic acids, and, according to Prout, with uric acid also. It is developed during the putrefaction of organic substances containing nitrogen. Free ammonia has been detected by Chevallier in some plants—for example, *chenopodium vulvaria, sorbus aucuparia*, &c. Raspail considers that the varieties of the glutinous and albuminous tissues are composed of *organic atoms* (each consisting of an atom of carbon united with an atom of water) combined with *ammonia* as a base; while in woody fibre the organic atoms are combined with a fixed base: so that the nitrogen, described by chemists as forming an elementary constituent of gluten and albumen, is, according to this notion, in combination with hydrogen.

Production.—Ammonia is primarily obtained either from the decomposition of animal matters, or in the manufacture of coal gas. I shall very briefly allude to the first, though I believe nearly all the ammonia of commerce is now obtained from the latter source.

(*a*) *Production of muriate of ammonia by the destructive distillation of animal matters.*—Bones, or refuse animal matters of any kind, are distilled in a cast-iron cylindrical retort or still. The products of the operation are a *brown liquor* containing carbonate of ammonia, an *empyreumatic tar-like oil*, and a quantity of fœtid inflammable *gas*. By mechanical means the greater portion of the oil is separated, and the residual liquor constitutes what is denominated *rough bone spirit;* by a second distillation at a more gentle heat, nearly all the residual oil is removed, and the distilled liquid constitutes the *spirit of hartshorn*—that is, an aqueous solution of carbonate of ammonia, with some empyreumatic oil. The rough bone spirit, however, is usually digested on ground plaster of Paris (sulphate of lime), and by double decomposition there are produced sulphate of ammonia in solution, and insoluble carbonate of lime. The liquid, containing the ammoniacal sulphate, is concentrated, and common salt added; by evaporation, double decomposition takes place, sulphate of soda and muriate of ammonia being the results: the first crystallizes, while the second remains in solution in the mother water. This is evaporated until the muriate of ammonia crystallizes, when it is purified by sublimation in earthen jars. In Aikin's *Dictionary of Chemistry* will be found a detailed account of this operation.

The *theory* of the process is not difficult to comprehend. Animal matters (as the gelatine of bones) are composed of carbon, hydrogen, oxygen, and nitrogen. By heat in closed vessels these elements enter into new combinations. Thus, some of the oxygen and hydrogen unite to form *water;* carbon and oxygen, combining in different proportions, furnish *carbonic oxide* and *acid:* carbon with hydrogen forms *carburetted hydrogen;* while the nitrogen, uniting with hydrogen, produces *ammonia*, which, with the carbonic acid, forms carbonate of ammonia: carbon and hydrogen, with a little oxygen, constitute the *empyreumatic oil.* By the action of the sulphate of lime on the carbonate of ammonia, we obtain sulphate of ammonia and carbonate of lime.

Re-agents.	Results.
$Am + \ddot{C}$	$Am + \dddot{S}$
$\dot{Ca} + \dddot{S}$	$\dot{Ca} + \ddot{C}$

The sulphate of ammonia is then decomposed by the common salt, and by the aid of water, we get sulphate of soda and muriate of ammonia.

Re-agents.	Results.
$Am + \dddot{S}$	$Am + H\ Chl.$
$\dot{H}$	$\dot{Na} + \dddot{S}$
$Na\ Chl.$	

(*b*) *Production of muriate of ammonia in the manufacture of coal gas.*—In the distillation of coal, as practised at the gas-works, the volatile matters are conveyed to a condensing vessel, or refrigeratory, in which tar and an ammoniacal liquid are deposited. This liquor contains several ammoniacal salts, as the sulphate, carbonate, hydrocyanate, and hydrosulphate. By the addition of sulphuric acid these are converted into the sulphate, which is obtained by evaporation, in the form of brown crystals: these are sublimed with common salt in order to furnish the muriate of ammonia. The *theory* of the process is as follows:—Coals consist essentially of carbon, hydrogen, nitrogen, and oxygen, and there is also usually present more or less of sulphuret of iron; so that, you observe, there are all the elements in coal to furnish the ammoniacal salts just mentioned. The sulphate of ammonia obtained by saturating the ammoniacal liquid with sulphuric acid, is decomposed by the common salt, and by the aid of a little water the products obtained are muriate of ammonia and sulphate of soda, as in the last mentioned process.

The sublimation is carried on in an iron pot lined with clay: the head of the pot being perforated in the middle. After the operation, there are found imbedded in the clay beautiful and perfect crystals of the bisulphuret of iron.

Sometimes sulphuric is substituted for muriatic acid in saturating the ammoniacal liquid, and, by evaporating, crystals of rough muriate are obtained, which are sublimed in the iron pot, as in the other process, but without the addition of common salt.

1. *Of Ammoniacal Gas.*

Preparation.—This gas is procured by mixing equal parts, by weight, of muriate of ammonia and quick lime, introducing the mixture into a retort, and collecting the gas over mercury; or, in the absence of a mercurial apparatus, we may generate the gas in a Florence flask, and, by means of a tube curved twice at right angles, collect the evolved gas in bottles by displacing the atmospheric air.

The *theory* of the process is as follows:—One proportion of the muriate is acted on by one proportion of lime, giving rise to

one of ammonia, one of water, and one of chloride of calcium.

Re-agents.	Results.
Am + H Chl.	Am.
$\dot{\text{Ca}}$	$\dot{\text{H}}$
	Ca Chl.

Physical and chemical properties.—It is a colourless, invisible gas, having a strong and well-known odour; it reddens turmeric paper, but the application of heat restores the original yellow colour. It is decomposed by heat into its constituents, hydrogen and nitrogen, every two volumes of ammonia yielding three volumes hydrogen and one nitrogen: mixed with oxygen it forms an explosive mixture.

Before explosion.		Results.	
Amm. =17	Ox. =16	Nitr. =14	and Water =27
	Ox. =8		

You will observe from this diagram that two volumes of this gas require one volume and a half of oxygen for its complete combustion. Chlorine acts powerfully on ammonia, producing muriate of ammonia and nitrogen. With the vapour of muriatic acid, it forms copious white fumes of the muriate of ammonia. The specific gravity of this gas is about 0.59.

Characteristic tests.—Its odour, its action on turmeric, and the white fumes with muriatic acid, readily distinguish it. When dissolved in water, the solution may be recognized by other characters to be noticed presently.

Physiological effects. — Ammonia is a powerful local irritant. This is proved by its pungent odour, and its acrid and hot taste — by its irritating the eyes, and, when applied for a sufficient length of time to the skin, by its causing vesication. If an attempt be made to inhale it in the pure form, spasm of the glottis comes on; when diluted with atmospheric air, it irritates the bronchial tubes and larynx, and, unless the quantity be very small, brings on inflammation of the lining membrane. Nysten injected some of this gas into the veins of a dog: the animal cried out, the respiration became difficult, and death soon took place. Neither gas nor visible lesion was observed in the heart, the two ventricles of which contained liquid blood. In another experiment he threw ammoniacal gas into the pleura of a dog: cries, evacuation of urine, and vomiting, immediately followed; soon afterwards convulsions came on, and continued for several hours; ultimately they ceased, and recovery took place.

In almost all cases of poisoning in animals, by ammonia, or its carbonate, convulsions are observed, apparently shewing that these substances act on the spinal marrow. The proper medicinal or therapeutical effect of these preparations on the system in general will be examined under the head of the solution of ammonia.

Uses.—Ammoniacal gas is rarely employed in medicine. Bourguet de Béziers employed it in the case of a child affected with croup, to provoke the expulsion of the false membrane.

Antidotes.—Inhale the vapour of hot vinegar, muriatic acid, &c.

2. *Solution of Caustic Ammonia.*

General remarks, synonymes, &c.—Ammoniacal gas and water have a strong affinity for each other. This may be readily proved by opening a phial filled with the gas under water: the liquid rushes up with such violence as sometimes to fracture the bottle. The quantity of the gas which water can dissolve varies with the pressure and temperature. Sir H. Davy says, that at a temperature of 56°, and under a pressure equal to 29·8 inches of mercury, water absorbs 670 times its volume, and becomes of specific gravity 0·875. Such a solution would contain 32·5 per cent. of its weight of gas.

In the Pharmacopœia we have an officinal solution much weaker than the one here alluded to; it is denominated *liquor ammoniæ*.

Preparation.—It is prepared by distilling a mixture of quick-lime, muriate of ammonia, and water. The sulphate might perhaps be manufactured at a cheaper rate, and would answer equally well. The *theory* of the process is simple: the lime abstracts the muriatic acid, and the ammonia distils over with some water. By the mutual action of the muriatic acid and lime, we obtain water and chloride of calcium. These symbols will explain the decomposition:—

Substances employed.	Results.
Am + H Chl	Am
$\dot{\text{Ca}}$	Ca Chl
	$\dot{\text{H}}$

Physical and chemical properties.—It is a colourless liquid, having the smell and alkaline properties of the gas already described. Its specific gravity is 0·960. Here is an extract from Sir Humphry Davy's table of the quantities of ammoniacal gas in solutions of different specific gravities:—

Specific Gravities.	Per centage quantity of Ammonia.
0·9572	10·82
0·9597	10·17
0·9619	9·60
0·9692	9·50

You will observe from this table, that a solution having a specific gravity of 0·960 must contain very nearly 10 per cent. of ammonia; so that the officinal solution will consist of—

Ammonia	10	or 1 atom	17
Water	90	or 17 atoms	153
	100		170

Characteristic tests.—Solution of ammonia is characterized by its odour, its temporarily reddening turmeric, its fuming when a rod moistened with strong liquid muriatic acid is brought near it; by its producing a deep blue solution when added in excess to a solution of the salts of copper; and, lastly, when chloride of platinum is added to it, a yellow precipitate (*chloro-platinate of muriate of ammonia*) is produced.

Impurities.—Liquor ammoniæ frequently contains traces of the carbonate, which may be detected by lime-water, or by a solution of the chloride of calcium, either of which occasions a white precipitate of the carbonate of lime. When a portion of the liquid has been neutralized by pure nitric acid, it ought not to cause a precipitate by the addition of the nitrate of silver, or oxalic acid; for the first would indicate the presence of muriatic acid, or chlorine; the second, of lime.

Incompatibles.—It is hardly necessary to say that all acids are incompatible with ammonia. With the exception of the salts of potash, soda, lithia, lime, baryta, and strontia, ammonia decomposes most salts.

Physiological effects. — Let us examine these under the two heads of local and remote effects:—

(*a*) *Local effects.*—In the concentrated form the local action of liquor ammoniæ is exceedingly energetic. Applied to the skin it causes pain, redness, vesication, and destruction of the part; thus acting first as a rubefacient, then as a vesicant, and lastly as a caustic or corrosive. Its emanations are also irritant: when they come in contact with the conjunctival membrane, a flow of tears is the result; when inhaled, their powerful action on the air-passages is well known. You observe persons in syncope, almost immediately raised from a death-like state, merely by causing them to inhale the vapour of this solution. Whenever you employ it in cases of insensibility, bear in mind that you are using a powerful local irritant; and unless administered with caution, you may give rise to most serious, or even fatal consequences. Nysten tells us that a physician, for some years subject to epilepsy, was found by his servant in a fit. In order to rouse his master, the latter applied a handkerchief moistened with this solution to the nose, so assiduously, that he brought on bronchitis, of which the physician died on the third day. In the Edinburgh Medical and Surgical Journal there is the report of the case of a lad whose death was produced, or at least hastened, by an attendant applying "with such unwearied but destructive benevolence" ammonia to the nose, that suffocation had almost resulted. Dyspnœa, with severe pain in the throat, immediately succeeded, and death took place forty-eight hours afterwards. A French physician also suffered ulceration of the mouth, and violent pulmonary catarrh, in consequence of the excessive use of ammonia, given as an antidote for hydrocyanic acid.

I have referred to these cases with the view of strongly impressing on you the necessity of exercising great caution in the application of this agent.

When the liquor ammoniæ is swallowed in large doses, it acts as a powerful corrosive poison. Fortunately we do not meet with frequent examples, so that the symptoms and appearances are rather assumed from analogy than from any modern well-marked cases in the human subject. However, it is very evident that violent inflammation of all that part of the alimentary canal with which the poison may be in contact, would be the result, and that if much be taken, decomposition of the part might be expected. When swallowed in a very dilute form, and in small quantity, the local phenomena are not very marked, and the effect of the substance is then seen in the affection of the general system.

(*b*) *Remote effects.* — Let us investigate these under two heads, according as they are produced by small or large doses:—

(*α*) *Effects of small, or therapeutic doses.*—When administered in those quantities we are accustomed to employ in the treatment of diseases, ammonia acts as a stimulant, excitant, or calefacient. It produces a sensation of warmth in the mouth, throat, and epigastrium, frequently attended with eructations. The pulse is soon rendered quicker and fuller; the heat of the skin is sometimes increased, and there is a tendency to sweating, which, if promoted by the use of warm diluents and clothing, frequently terminates in copious perspiration. But the skin is not the only secreting organ stimulated to increased exertion; we observe the kidneys produce

more urine, and frequently the quantity of bronchial mucus is increased. The nervous system is also affected. Wibmer has made several experiments on himself, and from them it appears that ammonia affects the head, sometimes causing oppression, or a sense of fulness, but no pain.

The increased capability of muscular exertion, the excitement of the mental functions, and the greater facility with which all the functions are executed, are further indications of the action of ammonia on the nervous system.

(β) *Effects of large, or poisonous doses.*—I cannot better introduce this subject, than by reference to some experiments made by Orfila. He injected 60 grains of liquor ammoniæ into the jugular vein of a strong dog; tetanic stiffness immediately came on, the urine passed involuntarily, and the animal became agitated by convulsions: death took place in ten minutes. The body was immediately opened, when the contractile power of the muscles was found extinct.

In another experiment 36 grains of concentrated solution of ammonia were introduced into the stomach, and the œsophagus tied: in five minutes the animal appeared insensible, but in a few moments after was able to walk when placed on his feet; the inspirations were deep, and his posterior extremities trembled. In twenty hours he was insensible, and in twenty-three hours died. On dissection the mucous membrane of the stomach was found red in some places.

I have referred to these cases in order to show the effects of large doses of this solution on the nervous system. The first experiment, you will observe, agrees in its results (that is, in causing tetanic convulsions) with that made by Nysten, of throwing ammoniacal gas into the cavity of the pleura. From the convulsions it may be inferred that in these instances the spinal marrow was specifically affected.

On the human subject we hardly know its action in very large doses; but that the nervous system is affected seems probable from a case mentioned by Plenck, which terminated fatally in four minutes; though the symptoms are not related.

The *modus operandi* of ammonia deserves to be noticed. Does ammonia become absorbed? I am not acquainted with any facts which can enable us to decide this question. Even admitting that absorption does take place, it is more likely that the remote effects are of a sympathetic kind, than the result of the absorption. In calculous complaints ammonia and its subcarbonate may be used with considerable advantage in those cases where potash and soda are serviceable; from which I think it probable that, like the fixed alkalies, ammonia taken into the stomach would be evolved by the kidneys.

Uses.—We resort to a solution of ammonia, properly diluted, on a variety of occasions, some only of which can be here noticed.

1. *To neutralize acid.*—In dyspeptic complaints, accompanied with preternatural acidity of stomach, and flatulence, but without inflammation, a properly diluted solution of ammonia may be employed with a two-fold object—that of neutralizing the free acid, and of stimulating the stomach. And here I would remind you, that the healthy secretions of the stomach are of an acid nature, and doubtless, therefore, this condition has its proper uses; so that the continued use of ammonia, or any other alkali, must ultimately be attended with injurious results, more especially to the digestive functions. While, therefore, the occasional employment of alkalies may be serviceable, their constant or long continued use must ultimately be deleterious. But I shall more particularly examine this point, when speaking of potash and soda.

Ammonia may, under some circumstances, be employed to neutralize acids introduced into the stomach from without, as in poisoning by the mineral acids, though chalk and magnesia would be more appropriate, being less irritant. I mentioned in my last lecture that ammonia was a valuable antidote in poisoning by hydrocyanic acid. This was at one time referred to its uniting with the acid, thereby forming the hydrocyanate of ammonia; but since it has been found that this salt is highly poisonous, it is evident that this explanation is not satisfactory. Some have ascribed the activity of the hydrocyanate to its decomposition by the free acids of the stomach, and the consequent evolution of free hydrocyanic acid, but to me the explanation is unsatisfactory. I therefore believe the efficiency of ammonia as an antidote to poisoning by hydrocyanic acid, arises from its exerting an influence of an opposite nature to that of the poison. I need hardly say that in poisoning by the oil of bitter almonds, or other agents supposed to contain this acid, ammonia is equally serviceable. Let the remedy be given by the stomach, if the patient can swallow, and also let the vapour be inhaled, constantly keeping in mind the caution already given.

2. *To produce local irritation, rubefaction, vesication, or destruction of the part.*—As a *local agent*, ammonia has been employed in a variety of diseases, sometimes as a rubefacient or irritant, sometimes as a vesicant, and occasionally as a caustic. Thus it is employed as a rubefacient in

rheumatic and neuralgic pains, and as a counter-irritant to relieve internal inflammations. As a local irritant, a weak solution has been injected into the vagina and uterus, to excite the catamenial discharge; but there are some objections to its use. Thus, it is a most unpleasant kind of remedy, especially to young females; moreover, the stoppage of this discharge is in many cases dependent on constitutional or remote causes, and, therefore, it is unlikely a topical remedy can be beneficial. However, some may feel inclined to try it, and on that account I may state that Lavagna employed 10 or 15 drops of the solution diluted with milk. The following is Nisato's formula:—

℞ Ammon. liquid. gtt. xl.; Decoct. Hordei, unc. viii.; Mucilag. arab. unc. dimid. Misce, et fiant quatuor intra diem injectiones.

Sometimes ammonia has been employed as a vesticatory; and it has two advantages over cantharides—a more speedy operation, and not affecting the urinary organs. I shall presently give you a formula for making a vesicating ointment; or you may apply the solution of ammonia itself. As a caustic, the strong solution of ammonia may be sometimes employed with advantage in the bites of rabid animals.

3. *The vapour of the solution of ammonia may be inhaled* when we wish to make a powerful impression on the nervous system, as in syncope, or to prevent an attack of epilepsy. To guard against, or relieve fainting, ammoniacal inhalations are very powerful and useful; their instantaneous operation is frequently astonishing. Pinel says he once saw an attack of epilepsy prevented by this means. The patient (a watch-maker) had intimations of the approaching paroxysm from certain feelings, but he found by inhaling the vapour of ammonia, it was frequently prevented. In the case of a confirmed epilepsy which I was in the habit of watching for some years, I think I have also seen analogous beneficial effects. I speak doubtfully, because it is so difficult to determine, in most cases, the actual approach of the fit.

In asphyxia, ammoniacal inhalations have been strongly recommended by Sage, who says that he produced the apparent death of rabbits by immersion in water, and recovered them subsequently by the use of ammonia. A case is told us of a man who had been submerged in the Seine for 20 minutes, and who, when taken out of the water, appeared lifeless, yet by the use of ammonia recovered; and a M. Routier, a surgeon of Amiens, is said to have restored a patient in the same way. That it may sometimes be of service I can readily believe, but it must be employed with great caution.

4. *Ammonia is given internally as a stimulant and sudorific* in a variety of cases, with manifest advantage. In recapitulating these, I must be very brief: (*a*) in continued fevers which have existed for some time, and where all violent action has subsided, and the brain does not appear much disordered, ammonia is occasionally of great service. You should promote its diaphoretic action by diluents and warm clothing. It has an advantage over opium, that if it do no good, it is less likely to do harm. (*b*) In intermittent fevers, ammonia is sometimes of advantage during the cold stage, to hasten its subsidence. Some persons, however, employ blood-letting in these cases, and I can bear testimony to the practice being unattended with any ill effects, though I have not seen benefit result therefrom. (*c*) In the exanthemata, when the eruption has receded from the skin, and the extremities are cold, a stimulant and diaphoretic, like ammonia, is sometimes of great benefit. But you must not lose sight of the fact, that in many of these cases the recession of the eruption arises from, or is connected with, an inflammatory condition of the mucous membrane, for which the usual treatment is to be adopted. (*d*) In some inflammatory diseases, where the violence of vascular action has been reduced by proper evacuations, and where the habit of the patient is unfavourable to the loss of blood, ammonia has been serviceable, more especially in pneumonia and rheumatism.

5. *In certain affections of the nervous system* ammonia is frequently employed with the greatest benefit. Thus it has been used to relieve the cerebral disorder of intoxication; Chevallier says, benefit is often, but not invariably, obtained from it. In poisoning by those cerebro-spinants commonly denominated *sedatives*, such as foxglove, tobacco, and hydrocyanic acid, ammonia is a most valuable agent. This remedy has been supposed to possess a specific influence in relieving those disorders of the nervous system accompanied with spasmodic or convulsive symptoms; and hence it is classed among the remedies denominated *antispasmodic*: but whenever it gives relief it is by its stimulant operation. Velsen, of Cleves, has used it with advantage in delirium tremens. It was a remedy frequently tried in the malignant or Indian cholera, and occasionally procured relief, but this effect was not sufficiently common to lead practitioners to place much reliance on it.

6. *Against the bites of poisonous animals*, as serpents and insects, ammonia is frequently employed with the best effects,

There does not appear, however, any ground for the assertion of Sage, that it is a specific: in fact, Fontana declares it to be sometimes hurtful in viper bites.

Antidotes.—The dilute acids, as vinegar, lemon or orange juice, &c.

3. *Carbonates of ammonia.*

Ammonia combines with carbonic acid in three different proportions, giving rise to three salts, termed, from their composition, *monocarbonate*, *sesquicarbonate*, and *bicarbonate*; and they are thus constituted:—

Monocarbonate.

1 Carbonic acid	22
1 Ammonia	17
1 Water	9
	48

Sesquicarbonate.

$1\frac{1}{2}$ Carbonic acid	33
1 Ammonia	17
1 Water	9
	59

Bicarbonate.

2 Carbonic acid	44
1 Ammonia	17
2 Water	18
	79

Of these three carbonates, two are contained in the Pharmacopœia—namely, the *monocarbonate*, found in the spiritus ammoniæ, and the spiritus ammoniæ aromaticus; and the *sesquicarbonate*, usually called the subcarbonate. The bicarbonate is not officinal, but by long exposure of the sesquicarbonate to the air, free ammonia is evolved, and the bicarbonate formed. How soon the carbonates of ammonia were known is not easy to say, since chemists were for a long time unacquainted with the difference between caustic and carbonated ammonia. Raymond Lully, in the thirteenth century, had obtained the carbonate from urine, but it is probable that it was known to the Arabian chemists long before.

(*a.*) Spiritus ammoniæ.—This is prepared by distilling proof spirit with muriate of ammonia and the subcarbonate of potash of the Pharmacopœia. By the mutual action of the muriate and the subcarbonate on each other, water, chloride of potassium, and monocarbonate of ammonia, result: the latter distils over with the spirit.

Reagents.	**Results.**
Am + H Chl.	Am + $\ddot{C}$
$\dot{K} + \ddot{C}$	$\dot{H}$
	K Chl.

This solution is more pungent than the solution of the sesquicarbonate which is kept in the shops: its effects and uses are similar.

(*b.*) Spiritus ammoniæ aromaticus.—This is a very analogous preparation to the last, except that the proportions of the ingredients are somewhat different, and, in addition, some aromatics are employed, —namely, cinnamon, cloves, and lemon-peel; so that the resulting spirit is weaker, but more agreeable.

(*c.*) Besides these spirits of ammonia, there are two others contained in the Pharmacopœia: the *spiritus ammoniæ fœtidus* (which I shall notice hereafter, in speaking of asafœtida), and the *spiritus ammoniæ succinatus*, a preparation containing a solution of caustic ammonia, oil of lavender, oil of amber, mastic, and rectified spirit, and which is commonly termed the *eau de luce*. It is a powerful stimulant, and has been employed against the bites of poisonous animals.

(*c.*) Sesquicarbonate of ammonia: *History and synonymes.*—This salt has been long known under a variety of names: in the Pharmacopœia it is denominated *subcarbonas ammoniæ*, probably on account of its alkaline properties; in the shops it is denominated *volatile* or *smelling* salts. It is employed by bakers in the manufacture of some of the finer kinds of bread, cakes, biscuits, &c. in which yeast is not used.

Preparation.—The salt is prepared by subliming muriate or sulphate of ammonia (in the Pharmacopœia the former is directed) with chalk. When we examine the process *theoretically*, we are at first astonished that although the salts employed are neutral, the resulting compound is not so. One atom of muriate of amnia, by theory, ought to yield, with one of chalk, an atom of monocarbonate of ammonia, one of water, and one of chloride of calcium. But the resulting ammoniacal salt is a sesquicarbonate, showing that part of the ammonia must have escaped in the process. The following symbols show the changes which take place:—

Reagents.	**Results.**
3 (Am + H Chl.)	Am + $\dot{H}$ $\triangle$
3 ($\dot{Ca} + \ddot{C}$)	2 ($Am^2 + \ddot{C}^3 + \dot{H}$)
	3 (Ca + Chl.)

When three atoms of muriate of ammonia react on three of carbonate of lime, one of ammonia and one of water escape; and two atoms of the hydrated sesquicarbonate of ammonia and three atoms of chloride of calcium are formed.

Properties.—It is met with in cakes,

which are fibrous, white, translucent, and about two inches thick. When exposed to the air, it evolves ammonia, and is converted into the bicarbonate; so that its vapour has a pungent odour, and strongly reddens turmeric paper. Its composition has already been stated. It is met with in the shops in various degrees of purity; the more impure kinds containing some empyreumatic oil.

The *liquor ammoniæ subcarbonatis* of the Pharmacopœia is really a solution of this sesqui-salt, in the proportion of four ounces of the salt to a pint of distilled water. It has the ammoniacal odour, and gives the results already mentioned as indicative of its containing ammonia. By lime-water we obtain a white precipitate of the carbonate of lime, soluble in acetic acid. The solution effervesces with any of the strong acids.

Physiological effects.—The *local* action is that of an irritant and corrosive, but it is much less powerful than the liquid caustic ammonia, in consequence of the presence of the carbonic acid, which in some degree neutralizes the alkaline properties of the ammonia present. Swallowed in large doses it excites pain, inflammation, and all the consequences of a violent irritant poison; while the immoderate inhalation of its vapour is capable of giving rise to violent bronchial inflammation.

The *remote* action of this salt is similar to that of caustic ammonia. Thus, in small doses, it has the same exciting action on the heart, brain, &c. and the same diaphoretic effect. The principal experimenters with this salt are Seybert, Orfila, and Gaspard, on dogs, and Wibmer on man. Seybert injected in one experiment fifteen grains, in a second twenty-five grains, and in a third experiment forty-five grains of this salt, dissolved in a little water, into the crural vein of a dog: the animal appeared to suffer great pain; the frequency of the heart's action was increased, the respiration became difficult, and violent convulsions came on; but in all these cases perfect recovery took place. The blood drawn after the injection had the natural colour, odour, and consistence. Orfila found that two drachms and a half of the salt, given to a dog, caused gastric inflammation, with tetanic convulsions; the body ultimately becoming curved, with the head forcibly bent backwards.

Wibmer's experiments were made on himself. A grain and a half of this salt produced no remarkable effect; three grains increased the frequency of the pulse from 68 to 72 beats per minute, with throbbing headache. In other experiments, in which he took from six to twelve grains (in some repeating the dose at short intervals), the effects were usually, but not constantly, increased frequency of pulse, with disorder of brain, manifested by the pain, heaviness, throbbing, &c. In one case, he says disposition to cough, and increased secretion of bronchial mucus, were remarkable.

Uses.—This salt is used in the same cases, and under the same circumstances, as the liquor ammoniæ; it would, therefore, be both tedious and useless to recapitulate these.

In some cases we employ this salt in the production of effervescing draughts. The following are the relative proportions of acid and base to be employed:—

20 grains of subcarbonate of ammonia (Ph. L.) will saturate about	6 fluid drachms of lemon juice. 26 grains of crystallized citric acid. 26 grains of crystallized tartaric acid.

The citrate and tartrate of ammonia, obtained as above, are useful in allaying nausea and vomiting; they are also feebly diaphoretic, and in some cases diuretic.

4. *Solution of Acetate of Ammonia.*

History and Synonymes. — This solution appears to have been first described by Boerhaave, in 1732, and was introduced by him among the articles of the Materia Medica. Subsequently it was employed by Mindererus; and hence it obtained one of its names, *spiritus seu liquor Mindereri.*

Preparation.—The *liquor ammoniæ acetatis* of the Pharmacopœia is prepared by dissolving the so called subcarbonate in acetic acid; by which the carbonic acid is expelled, and an acetate of ammonia formed in solution. Of course the quantity of ammonia dissolved depends on the strength of the acetic acid. If the latter be prepared according to the directions in the Pharmacopœia, its sp. gr. is about 1·009, and a pint of it will require very nearly seven drachms of the subcarbonate.

Properties. — When the acetic acid and the ammoniacal salt are both pure, the solution should be perfectly colourless. Any tint, therefore, which the solution of the shops may have, is referrible to impurities in the substances employed. I would remark, it is always better to employ a little excess of acetic acid; for if the ammonia preponderate, the solution is highly irritant, and if used as a collyrium, might produce inconvenient results. In regard to *incompatibles*, I need hardly tell you that acids, alkalies, and most metallic salts, produce chemical changes when mixed with it. It is a very

common practice to combine sulphate of magnesia with the acetate of ammonia; and although double decomposition takes place, no precipitate is produced. Pure acetate of ammonia gives no precipitate with a solution of acetate of lead, but owing to the presence of a little carbonic acid, the liquor ammoniæ acetatis of the shops usually does. You ought, therefore, not to combine them, more especially as Dr. A. T. Thomson says the carbonate of lead which is formed is much more likely to occasion colic than the acetate of lead.

Physiological effects.—Its action is exceedingly slight. "I have known," says Dr. Cullen, "four ounces of it taken at once, and soon after four ounces more, without any sensible effect." It is reputed, however, to be diaphoretic, and sometimes diuretic; but to produce these results, it must be given in very much larger doses than is usually done. Wibmer tried on himself the effects of repeated doses of it, but did not observe any diaphoretic, diuretic, or purgative operation. It is a slight local irritant.

Uses.—It is employed both externally and internally. In cold lotions it is frequently used as a refrigerant; and in febrile affections it is one of the most common constituents of the saline draught, generally combined with a solution of tartar emetic, and sometimes with the spiritus ætheris nitrosi.

5. *Muriate of Ammonia.*

History.—I have already mentioned that the date of the discovery of this salt is not well ascertained. It is commonly known by the name of *sal ammoniac;* Berzelius terms it *chloride of ammonium.* In Thomson's History of Chemistry, as also in Parr's Medical Dictionary, will be found many other synonymes.

Preparation.—The methods now adopted for procuring this substance for commercial purposes, I have already mentioned. Some years since, a M. Leblanc, chemical manufacturer at St. Denis, near Paris, procured it by synthesis — that is, by bringing ammoniacal and muriatic acid gases together in a leaden chamber. The ammonia was generated by burning various animal matters in iron cylinders; the muriatic acid was obtained by the action of sulphuric acid on common salt. In Parkes's *Chemical Essays,* you will find an account of the process, with a ground-plan of the laboratory. The natives of Egypt did (and perhaps now do) obtain it by sublining the soot produced by the combustion of the dung of camels, oxen, and other animals. By reference to Parkes's work, just alluded to, you will find an account of other processes.

Properties.—In commerce it is usually met with in large cakes; they are translucent, and become slightly moist in the air. It may be obtained in regular octahedrons; and occasionally these are met with in the subliming pots. It produces cold in the act of dissolving in water.

Composition and nature.—There are two modes of viewing the composition of this salt—either as consisting of muriatic acid and ammonia, or as being a chloride of ammonium. Ammonium, according to the views of Berzelius, is a suppositious metal, composed of 4 proportions or atoms of hydrogen, and 1 of nitrogen. Here are the symbols for both views.

$$H^3 N + H\ Chl. \qquad H^4 N + Chl.$$

For the advantages and inconveniences attending Berzelius's theory, I must refer you to the fifth volume of Dumas' valuable *Traité de Chimie;* pharmacological lectures being, I conceive, unsuited to these details.

Characteristic tests.—It is a white volatile solid. By placing a small portion of it on the point of a knife, and introducing it into the flame of a candle, we may readily demonstrate its volatility. If a little be rubbed with caustic potash or quick lime, ammoniacal gas is evolved, which may be recognized by its odour and other properties, already pointed out. That it is a muriatic salt, is shown by the action of the nitrate of silver causing a white precipitate of the chloride of silver, soluble in ammonia, and insoluble in nitric acid. If a solution of the muriate be added to a solution of the chloride of platinum, a yellow precipitate takes place, which is the *chloro-platinate of the muriate of ammonia:* a similar precipitate is produced by chloride of platinum with the salts of potash, but not with those of soda.

Physiological effects.—The *local* action of muriate of ammonia is that of an irritant, and, therefore, when swallowed in large quantities, nausea, vomiting, purging, with inflammation of the alimentary canal, may be expected. I am not aware, however, of any cases of this kind having occurred in the human subject; but the experiments of Orfila and Arnold have shown these to be the effects on other animals. As to the *remote* action of this substance on man, Wibmer is the only one—as far, at least, as I know—who has experimented with it. He tried it on himself in doses of from 10 to 20 grains, repeating the quantity at the end of an hour: the effects were—sensation of warmth in the stomach, pulse slightly increased, head oppressed, and increased desire to pass the water. Courten, Sprögel, Viborg, and Gaspard, have tried the effects of injecting

solutions of it into the veins of animals (dogs and horses): convulsions were generally observed. According to the experiments of Orfila, Smith, and Arnold, it would appear, that to whatever part of the body this salt be applied, inflammation of the stomach is produced.

Uses.—Muriate of ammonia is principally employed, dissolved in water, as an irritant application to the skin. I have seen it serviceable in chronic affections of the joints. It has also been used for a variety of other local purposes, namely, as a constituent of a dentrifice, as an application to ulcers, skin diseases, &c.; as an ingredient in stimulating gargles and collyria, &c.

Internally, it has been recommended in gout and rheumatism, and in catarrhal complaints.

6. *Ammoniacal Liniments.*

I have already, on more than one occasion, alluded to the employment of ammonia, when combined with fatty bodies.

(*a*) The *linimentum ammoniæ fortius* of the Pharmacopœia is prepared by mixing one part of the liquor ammoniæ with two of olive oil.

(*b*) The *linimentum ammoniæ subcarbonatis* is made with a solution of subcarbonate of ammoniæ, and three parts of olive oil.

Both these liniments may be employed with advantage to relieve rheumatic and neuralgic pains, sore throat, and various other complaints where stimulants to the skin are likely to be useful.

7. *Ammoniacal Ointment.*

In France an ointment is employed called *liparolé d'ammoniaque*, or *pommade ammoniacale de Gondret*, composed of 8 parts of solution of ammonia, mixed with 8 parts of fatty matter (7 lard and 1 mutton suet). The mixture thus obtained, if rubbed on the skin, and covered by a compress, produces very speedily vesication; but rubbed on the skin without the compress, it occasions only rubefaction, owing to the escape of the ammonia. This preparation might, I think, be usefully employed where counter-irritants or vesicants are required.

OF THE EMPYREUMATIC OIL OBTAINED BY THE DISTILLATION OF ANIMAL MATTERS.

General remarks.—I have previously alluded to *empyreumatic oil* as a product of the decomposition of animal substances by heat. Thus, in the distillation of bones, an oil is obtained by the decomposition of the gelatine, which has been termed *Dippel's* oil, being, in fact, the same as the *oleum cornu cervi*, or *oil of hartshorn*, and which, until very lately, was an officinal article.

Effects.—It is a very powerful agent, and in large doses has produced death. Its local action is that of an irritant; while its remote effects are principally observed in the nervous and vascular system, on which it acts as a stimulant.

Uses.— It has been employed as a local remedy in bruises, gangrene, porrigo, &c. Internally, it has been used to prevent an attack of epilepsy or ague, as a stimulant in low fevers, and those cerebro-spinal disorders accompanied with convulsive movements, as hysteria; lastly, it has been given as an anthelmintic. The favourite remedy of Bremser against tape-worm, is *Chabert's oil*, which is prepared by mixing three parts oil of turpentine with one part Dippel's oil, and distilling three parts.

Dose.—A few drops, cautiously increased.

LETTER ON THE BLIND*.

By Monsieur A. Rodenbach,

Member of the Chamber of Deputies, Brussels.

[Concluded from p. 731.]

Miss Wilson, the daughter of the celebrated General Sir Robert Wilson, lost her eyesight in her infancy in a most distressing manner. During the campaign in Egypt, General Wilson was attacked by that dreadful ophthalmia which has been fatal to so many thousand Europeans. His wife, the tenderest of wives and mothers, devoted herself to the care of her husband, and she soon felt the effects of this pestilence. Their little child, this darling girl, never quitted them a moment, and consoled them by her caresses; but this terrible affliction extended to her also; and when her parents recovered their sight, they had to weep over the object of their tenderest affections consigned to everlasting darkness. When peace was concluded, and the Bourbons restored to France, General Wilson came to Paris; and it was in that capital that I obtained some information about his daughter, whose fate interested every one who saw her. They all praised her

---

* In the former part of the letter, *Rodenbeck* was substituted for *Rodenbach*. Also at page 731, *for* "sew a little circumference on the silk of the different countries," *read* "sew a little silk on the circumference," &c. It may be proper farther to add, that we have slightly condensed the letter, particularly by the omission of some verses.—Ed. Gaz.

mildness, her sweet manners, and that modesty which is the most precious dowry of her sex. She added to these qualities a superior mind, much information, and a most extraordinary memory. She was well acquainted with English and French literature, and could recite the most beautiful passages in both languages from memory. Early accustomed to the highest class of society, it is not surprising that she was distinguished by the excellent tone of her manners; but she would have been remarkable in every class of society for her love to her parents, her tender feeling for all unfortunate persons, and her generosity to the poor, which caused her to be revered by all around her, and afforded a continual source of consolation in her own affliction.

Miss Sophia Osmont, a blind young lady of 18, is the daughter of Madame Mirette, one of the most talented actresses in France, and the best comic performer of the Vaudeville. This lady is constantly employed in the education of her daughter, who may be compared to Miss Wilson in information and elegance of manner. This young lady plays admirably on the piano, and on the harp. She executes the finest passages of music with a precision and steadiness which are most rare. She is very partial to foreign literature. The best French and Italian authors are familiar to her. She understands geography, and writes and casts accounts remarkably well. But the most singular and surprising of all her talents is, that she teaches her mother all her parts : this requires explanation. The mother reads her part aloud ; her daughter, gifted with a prodigious memory, knows it directly by heart, and then she in her turn repeats continually all the phrases of the part, to alleviate this painful task to her mother. I have been present at this exercise, and I own it interested me greatly. Sophia is gifted with the rarest qualities ; and this is still more remarkable, as she may be said to have been blind from her birth, having been seized almost at the first moment of her existence with convulsions, which deprived her of sight. The inimitable Mars gave her many proofs of interest and friendship, and went often to see her. Thus when you saw the lovely Mars play "Valeria," it was Sophia that she copied, and all her peculiar blind manners ; for this celebrated actress always studied nature in order to represent it on the theatre with that truth which was her peculiar attribute. As a proof of her attachment to Sophia Osmont, she made her a present of a bracelet of great value, and of the most exquisite work, upon which I read in characters in relievo, "Valeria to Sophia." Madame Minette collects a charming society around her.

May I be permitted to consecrate some lines to my remembrances, and to deplore the death of a female, the honour of her sex, who has been lately torn from her friends. Mad. Defosseux-Virnot, of Lille, lost her sight in early youth, in consequence of a paralysis of the optic nerve. Far from being depressed by so great a misfortune, she occupied her mind in the acquisition of knowledge, and turned every thought to the study of philosophy and literature. She became one of the most enlightened and best-informed women who have ever ornamented society. Good, mild, always amiable, she lived adored by her family, and by all who surrounded her. Severe suffering had not altered her angelic temper, and she possessed in a most eminent degree that evenness of temper which, according to a great man, constitutes true education, passionately devoted to the study of philosophy, but of that philosophy which sprung from a strong and liberal mind, superior to prejudice. From the natural strength of her mind, and her extreme good sense, this lady, so justly regretted, was formed for society, but she quitted it without regret, for study, solitude, and friendship. She repeated often to the two female friends who were constantly with her this proverb :—"friends ought to agree to die the same day." She died in their arms, preserving the perfect use of her faculties to the last moment.

M. Heilmann is a scholar of Pfeffel, and of Valentine Hauy ; his memory is prodigious ; he possesses the most extensive knowledge of history ; not a single detail escapes him ; he has employed himself with philosophy, has studied all the German authors, and is profoundly conversant with their literature : he has written a most excellent work on education, which has gained him the friendship of M. Maron, the head of the

protestant church in France. Under the empire, M. Heilmann was at the head of a very considerable cotton manufactory. Many invalid blind men wove calicoes in his manufactory, and some disabled soldiers with wooden legs mended the threads and overlooked the frames at which the blind men worked.

You will, perhaps, have thought it strange that the blind should marry their fellow-sufferers. There are many examples of such marriages, and M. Hauy encouraged them very much; his experience led him to discern that such weddings made happy families. Children from these unions generally see well. This is not always the case when the deaf and dumb marry their companions in affliction: it has been remarked that their descendants generally inherit their misfortune, whilst since the reign of St. Louis, history mentions only one family in which blindness was hereditary, and then the children lost their sight gradually. At 20 they saw well enough to walk by themselves, but at 40 were totally blind.

M. Alexander Fournier lost his sight in his infancy from the small-pox. His father, who was a merchant at Paris, put him under the care of M. Hauy, and he was one of his best scholars; he became in a few years one of the most intelligent of the blind. Few amongst them have excelled so much in the beauty of their hand-writing; he is a good geographer; and when he places his fingers on a map in relievo, he distinguishes the capital cities, rivers, &c. more quickly than a person whose sight is perfect: he is equally gifted in arithmetic, and by the help of his plank and leaden cyphers, he performs with the utmost celerity the most difficult sums and calculations; he reads very well in relievo, and decyphers music quickly in the same manner. I remember once, that at the musée of the institution for the blind, at Paris, M. Fournier and myself contrived to read with our toes the leaden characters. Another time, to perfect the sense of touch, we procured some pumice-stone, by the help of which we took off the epidermis of the fore-finger; when this operation was finished, we took great care to wear a leather finger-stool. M. Fournier has taken lessons from M. Paingeon, the most astonishing blind mathematician of his age. When M. Hauy was summoned to Russia by his Imperial Majesty to found an establishment for the blind, M. Fournier accompanied this celebrated professor to St. Petersburgh, and in this city he married a very amiable woman, whom he had the misfortune of losing some years ago. The only consolation he finds in this irreparable loss is, the attention he pays the education of his children, which he directs himself.

Lesueur was born at Lyons, and came to Paris: he was begging at the door of a church when M. Hauy saw him there, took pity on him, carried him home, and completed his education. In three years, or rather less, he taught him to read, write, and cast accounts; he understood geography and music; he was also successively a private tutor to his companions, and the head of the printing office. His spirit of order in business and accounts caused him to be employed as steward of the institution. He died some years ago at Paris. His wife was a blind woman. Avarice rendered this beggar ungrateful to his benefactor. M. Hauy said to me, whilst speaking of Lesueur, "Ingratitude is the daughter of selfishness, and the vice of little minds; we will not regret him,—I have had the pleasure of doing good." But this reproach addressed to Lesueur, proves nothing against the blind; for the numerous scholars of M. Hauy always cherish his memory, and look upon him as a father. This excellent man died some years ago, at his brother's, M. L'Abbé Hauy, professor of mineralogy in the Jardin des Plantes at Paris.

Madlle. Petronille Moens was born in Holland, in 1765, at Cubart, in the province of Friezeland. She lost her sight at three years old. Her father, a Protestant minister at Aardenbourg, discovering that she had a great taste for poetry and elegant literature, encouraged, by every means in his power, her taste for poetry. We have by her "Esther;" "Hugo Grotius;" "Jean d'Oldenbarneveld;" and "Les Frères de Witt." Her most celebrated works are, "The Spring," a poem, in three cantos, published in 1788; and afterwards, the "History of Humanity," and "Reflections on the Eighteenth Century." We discover in her writings some bold and brilliant sallies, which characterize the great poetical genius

of the author. On many different occasions she has carried off the academic prizes. She obtained the first prize at the Hague, for her poem entitled "Le Vrai Chrétien." She was also crowned at Ghent, for a poem on the Battle of Waterloo. Madlle. Moens has also published "Le Patriote Victorieux," and many other little works on the affairs of the day, now forgotten; but our Sappho of the Netherlands has completely succeeded in a romance, in prose, called "Caroline d'Eldemberg, ou la Fidélité conjugale éprouvée." This work appeared in 1819. Notwithstanding her advanced age, this lady does not suffer her lyre to repose, and her melodious strains are still heard. She published lately, at Amsterdam, her "Bouquet pour la Jeunesse." This kind of writing does her the highest honour. This Nestor of blind poets is universally esteemed for her virtues and her talents. She now resides at Utrecht.

M. Rocques, a poet, born at Montauban, is the more remarkable amongst the blind, because he has educated himself. Before coming to the Musée of the Blind at Paris, he had invented letters in relievo, in order to learn to read. He employed the same method for music. This literary man has translated, in verse, with much taste, the odes of Metastasio. He has often inserted in the journals some articles on literature, which are expressed with all the warmth of a southern imagination. He displays infinite sagacity in discovering the defects and the characters of persons with whom he is acquainted. When he is at Paris, and wants a servant as a reader, he advertises for one in Les Petites Affiches, which brings to his house a crowd of knavish valets; he asks for their certificates of character: but he knows how easily masters give a character for honesty to worthless servants, and whilst he pretends to examine their papers, the lively Gascon questions them with as much skill and sharpness as could be practised by an old justice of peace. He is rarely deceived in the choice he makes, selecting them entirely from their answers.

I need not eulogize M. Paingeon; it is sufficient to say that this extraordinary blind man is gifted with a spirit of order peculiar to himself. He possesses transcendant knowledge in mathematics, and may be justly called the Saunderson of his age. After having gained every prize in 1806, in the general assembly of the four Lyceums of Paris, he was named by the Grand Master of the University professor of mathematics to the Lyceum of Angers, where he teaches with the greatest success. As a reward for his talents, he has been recently created Chevalier of the Legion of Honour.

M. Delille, a blind man, belonging to the Quinze-Vingts, has carried to a high degree the metaphysics of the French language: he has the most admirable precision in his definitions. I do not hesitate in saying that he is one of the first grammarians in France. This name recals to my memory a still more celebrated Delille. You anticipate, without doubt, that I mean the French Virgil. Like Milton, whom he has translated so well, he lost his sight at an advanced age. During his emigration in Switzerland, he married Mdlle. Vandechamps, whom he often called his Antigone. The gossiping chronicles of Paris raised some doubts of the mildness and complaisance of this new Antigone. I give an anecdote on this subject, which, however, I will not vouch for:—Mad. Delille, unmindful of the softness of her sex, forgot herself so much as to throw an enormous folio volume at her husband's head. The tender poet answered, with the greatest calmness, "Madam, you really ought to bestow your caresses on a smaller scale." You see by this that the tender Antigone had no pity for the author of so many fine poems; but it appears to be ordained that great men are to endure feminine tempests occasionally: Socrates himself could not conquer Xantippe.

Happening to be some time ago at Mont-Morency, I wished to visit a literary blind man, the nephew of my countryman Gretry. I went to the hermitage of J. J. Rousseau. The Belgian composer, of glorious memory, had been the proprietor, but at his death his nephews became the possessors. M. F. Gretry gave me a most obliging reception, talked to me of Rousseau, and hastened to make me touch the table on which he wrote his immortal Heloise. I touched also the weeping willows planted by this most eloquent of writers. Almost opposite

are placed the heart and the bust of the memorable Gretry, with this simple and expressive inscription: — "His genius is every where, but his heart is only here." I displayed my astonishment that these precious remains were not at Liege, the country of this great composer; particularly as, in his will, he expresses his desire for it to take place. M. Flemand Gretry then told me that at the death of his uncle he had written to the authorities of Liege, to agree with them in what manner to send the precious remains; "but (added he) you will hardly believe that these gentlemen desired me to send the heart of my uncle by the Diligence, and to excuse its public reception. I was indignant, and still more angry, because at that time the Cossacks were pillaging France, and traversing the country in every direction."

I have spoken, in the beginning of this letter, of the lively disposition which is commonly possessed by the blind. I knew one at Paris, who, in the whole course of his life, had never felt sorrow: it was impossible to be more happy than he appeared. He was constantly jovial, making always puns and playing on words. His name is Barbier; he possesses an independent fortune; he goes every night to two or three theatres to amuse himself, and at the same time to learn by heart, without trouble, the new airs and couplets. This blind man is a musician, and his memory is so strong as to enable him to sing several pieces when he returns from the first representation of an opera. His motto is, "Liberty and independence."

I shall pass over in silence a crowd of blind persons who are well known in the arts and sciences; such as Aboulola, Aufidius, Cneus, Dydyme of Alexandria, Malaval, Buret, Lineman, Caralhi, Anastassi, Chauvet, Chatelain, Martin, Gambasias of Volterre, de Ries, Sir Henry Mayer, &c. as I believe I ought only to speak of those who particularly merited your attention.

As I thus occupy myself with the blind, I beg to submit a few questions to physiologists. Why are blind and deformed persons so anxious to marry? Why are there so many instances of longevity amongst the blind, whilst it seldom occurs amongst the deaf and dumb? Why are there hardly any cases of mental alienation amongst the blind? and why, in the Canton de Vaud, in Switzerland, are there 150 deaf and dumb in a population of 150,000 souls? This strange statistical anomaly appears also in the Canton of Berne.

I hope that you will forgive a blind man for his presumption in attempting to enlighten a person gifted with sight. On any other subject I should have begged instruction from you, but as learning removes all darkness, I have endeavoured to explain to you how in this respect even the blind may see.

I am, with profound respect,

Your obedient servant,

A. Rodenbach,

Member of the Chamber of Deputies, Brussels.

January 1836.

GERMAN MEDICAL INSTITUTIONS AND PRACTICE.

HEIDELBERG—AUGSBURG.

To the Editor of the Medical Gazette.

Sir,

In a recent number of the Gazette, where my work on Continental Medical Institutions is noticed, a wish is expressed for more information respecting the German schools and hospitals. I have, therefore, pleasure in forwarding an account of some of those which I had not previously visited.

The University of Heidelberg is one of the most ancient, having been founded in 1386; and although it suffered much during the wars of the seventeenth century, it subsequently recovered itself, and now ranks high among the German universities, especially as a school of medicine, to which the zeal and ability of its professors mainly contribute. Among these I may specially mention Tiedemann, professor of anatomy and physiology; Chelius, professor of surgery; and Nægele, professor of obstetricity. The students have the reputation of being attentive and zealous in the pursuit of knowledge; their number amounts to about six hundred, of which more than one-third attends the medical classes. The shortness of my visit, which occurred at vacation time,

prevented my obtaining information respecting the plan of study, the examinations, and the facility with which degrees are granted.

The building is a plain quadrangular structure, in the centre of the town: its interior is disposed in lecture-rooms and a hall for examinations. The library is in an adjoining building, and the museums of zoology, mineralogy, &c., are in the houses of the respective professors. The anatomical theatre and dissecting-rooms form part of an edifice, formerly an extensive convent. What was the chapel, is now the *locale* of Tiedemann's anatomical and pathological museum, which is well arranged, and contains several valuable preparations, especially those of the sympathetic, par vagum, and cervical nerves.

Augsburg has a general and a military hospital; the former, a large building, used some years ago as a work-house and house of correction, is situated in an open and salubrious part of the town, and is supported by funds subscribed at the time of its foundation, by contributions from the magistracy, and by a trifling quarterly tax on domestics and others of the inferior classes, who, when ill, thus acquire a right to admission. The wards are not large, but are well ventilated and clean, and contain about 130 beds, each of which is furnished with an enormous eider-down covering, which doubtless obviates, in many cases, the necessity for the exhibition of diaphoretics, and with several pillows, by which the patients are maintained in a half sitting posture. Individuals with acute, chronic, syphilitic diseases, and psora, are received; as also those labouring under mental aberration. There is likewise an obstetric ward. The professional duties are performed by a physician, a surgeon, an assistant, and a house-physician. The diseases most prevalent at Augsburg are bronchial, rheumatic, gastric, and hepatic affections; chlorosis, bronchocele, and nervous disorders. Typhoid and intermittent fevers are rare.

Rheumatism is extremely prevalent throughout Germany, to which circumstance, I have little doubt, the universal use of eider-down bed coverings contributes. The acute form is here treated by general and local bleeding and purgatives; diaphoretics and colchicum are only employed in the more chronic forms, the affected parts being enveloped in tow. Baths are not much used, and the locale is not in good order. In pulmonic inflammation, bleeding and refrigerant beverages are chiefly trusted to; blisters are used when the urgent symptoms are relieved. In hepatic and gastric derangement, the taraxacum is much used, in combination with small doses of calomel. Active purgation is had recourse to in many instances. Among the patients were — a case of epilepsy, of many years' standing, which had been materially benefited by the exhibition of indigo; a case of hemiplegia, in which great advantage had been derived from the rhus toxicodendron; another of paralysis of the hands and feet, without apparent cerebral affection, in which recovery was taking place from the use of strychnine. In the syphilitic wards, mercury appears to be the remedy almost exclusively employed; frictions are preferred to its exhibition by the mouth.

The department for the insane consists of nineteen cells, warmed by stoves, the windows being secured by iron bars and wire; each cell has an occupant, and contains no other furniture than a bed and a stool. Tranquil patients are allowed to walk in the exercise-ground, but the more intractable ones are confined to their cells; those who are furious are fixed to their beds by strong leather straps. Abstinence, the confining chair, and occasionally chains, are the other means of restraint employed. One of the most frequent causes of insanity in this part is religious enthusiasm: there appears to be neither moral nor medical treatment; in fact, these cells must be considered merely as places of detention. There is no good institution for the insane throughout the Bavarian territories.

On a future occasion, I will transmit some account of the medical institutions of Munich.—I am, sir,

Your obedient servant,

Edwin Lee.

Munich, Jan. 17, 1836.

Medicine is addition and subtraction: subtraction of what is in excess, and addition of what is deficient, in the system.—Hippocrates.

USE OF VERATRINE

IN THE

TREATMENT OF CHRONIC GLANDULAR SWELLINGS.

To the Editor of the Medical Gazette.

SIR,

SHOULD you deem the following short communication worthy of insertion in your pages, it may perhaps be the means of calling the attention of the profession to a few facts in regard to the use of veratrine which appear to me worthy of notice.

Whilst employing it in the form of friction in cases of chronic rheumatism attended by considerable swelling of the affected joints, I observed that the removal of the pain was followed by a marked diminution in the size of the articulation, and that in some instances, by steady perseverance in the treatment, the swelling disappeared; and from this circumstance I was led to try its effects in chronic glandular enlargements, and in these I have found it of much service, even in cases where iodine had ceased to be of any use. This last, though a valuable medicine, is found, like all others, to lose its efficacy when employed for a length of time, and it therefore becomes an object with the practitioner to be possessed of other remedies, to which he can have recourse if necessary, and which he may make use of alternately with it.

Veratrine is one of these; and after considerable experience of its effects in bronchocele, indolent tumors of the mammæ, bubo, and scrofulous tumors in different situations, I can recommend it as a useful external application. It has, besides, a few minor advantages: it may be rubbed over a painful tumor, and generally with the effect of giving immediate relief; it has no tendency to irritate the skin, which preparations of iodine often have, and the superfluous quantity of ointment may be removed with a little *warm* water and soap immediately after the friction is finished; and on these accounts it is preferable in tumors about the neck, as the part may be exposed immediately, if necessary.

The following is the formula I have generally employed:—

℞ Veratrinæ, gr. x.; Axung. ℥ss. M. ut fiat unguent.

A piece of this ointment, the size of a nut, should be rubbed for ten minutes twice a-day over the seat of the tumor; and at the end of every week an additional quantity of veratrine, in the proportion of five grains to the ounce, should be added to the prescription, so as to keep up the effect.

The other remedies which belong to the same class as veratria, namely, delphine and aconitine, have nearly the same effects; and it will often be found advantageous to substitute one of these for the veratrine, when its influence has become less by repeated application.

I am, sir,
Your obedient servant,
A. TURNBULL.

TWO CASES

IN WHICH

THE TRICHINA SPIRALIS

WAS LATELY FOUND.

To the Editor of the Medical Gazette.

SIR,

As every circumstance connected with the recent discovery of myriads of parasites pervading human muscles cannot be otherwise than interesting to the profession, I beg to send you a notice of two cases in which they have been lately observed at the London Hospital. One is the case of a man, apparently in good health, who was brought into the hospital in a state of insensibility, with a fracture of the skull, and died two days afterwards.

On examination, the thoracic and abdominal viscera were found healthy; and the larynx having been taken away for the purpose of dissection, the sterno-thyroideus and other muscles connected with the larynx were subsequently observed to be thickly studded with minute white specks, which, upon microscopical examination, proved to be cysts containing the trichina spiralis.

The other is the case of a man who had been many months in the hospital with a large aneurism at the commencement of the descending aorta, which had made its way through the anterior parietes of the chest, the patient having died exhausted.

The parts having been removed for the sake of preservation, numerous cysts were found in the various muscles of the neck, and in the diaphragm; but on minute inspection none could be detected in the heart or axillary nerves. In both cases the insects were examined by Mr. Owen, and found to correspond with those already described.

It is worthy of remark, that in the first case the presence of these insects appears to have been unconnected with disease elsewhere; nor could I learn that the man had experienced any uneasiness, or loss of muscular vigour.

I am, sir,
Your obedient servant,
THOMAS BLIZARD CURLING.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

PUBLIC EXAMINATIONS.

THAT respectable document—the Petition—which is to receive the signature of Chairman Meade, *on the part of the medical students of the metropolis*, and to be presented to parliament by the *honourable* member for Finsbury, has not yet made its appearance; or, at least, it has been studiously kept out of our way. We are particularly anxious to see it, in order to ascertain one point —viz. what the students are made to say in it in respect to *public examinations*. We are curious upon the point, because, whatever the Meade-and-Wakley document may say to the contrary, we have reason to know that public examinations are *not* an object of desire with the great body of the students.

In several of the metropolitan schools, we believe, there may be found some few noisy and disorderly pupils—the idlest of their class, and of course the worst prepared for any examination—who join in the cry for a public trial, with the secret hope, no doubt, that it will afford them the best chance of passing muster; their nerve and impudence, they trust, will bear them safely through the ordeal. We could almost wish there *were* a public examination instituted for the benefit of these worthies, for we know well what would be the result—most rare and deserved *plucking* — disgrace indelibly branded on them, not to be obliterated for their lives' length, and serving as an excellent example *pour encourager les autres*.

But if we understand aright the genius and character of the great mass of well-disposed students who frequent the schools, there is nothing of which we are more certain, than that a public display—an exhibition before a gaping crowd of grinders and groundlings—when passing an examination for their diploma, would be wholly abhorrent from them. The large majority of medical students of the metropolis is far from being represented by the riotous few who figure occasionally before the police magistrates, obtain for themselves a scandalous notoriety in the newspapers, and unfortunately bring a certain portion of ill-repute on the general body of their fellows—nay, on the profession itself. These are the "choice spirits" with whose aid certain wily adventurers raise perpetual disturbances, and promise to establish a new order of things. But, we repeat, of such are *not* composed the ingenuous youth who fill the benches, and attend regularly to the business of the schools. We use no exaggeration when we say that it is our firm conviction that there are no students in any other part of Europe better disposed, generally speaking,

than those of London: they are gentlemanly, orderly, and unpresuming, entertaining a proper respect for their teachers, and not easily led away by the ill example of mischievous agitators. Their chief desire is to pass into the order of practitioners by a fair and well-conducted examination: they want no theatrical formality: they are satisfied to abide by the award of a tribunal from which they only demand justice, tempered of course with a proper degree of courtesy.

It is quite another thing where this fair-play and this courtesy are denied; where the student may have reason to complain that justice has not been duly administered to him. Here the scene changes. A public examination is desired—is demanded; but only as a *dernier ressort*—on an appeal. As matters stand at present in the constitution of the Society of Apothecaries, it is known that there can be no alternative of this sort; and therefore the call for it can only be accounted a bravado: but we confess ourselves rather disposed to think that such an alteration in the laws of the Society as would sanction a public examination, under the circumstances just alluded to, would be both politic and wholesome.

The possession of that presence of mind that intrepidity, necessary for a public trial, is a talent not very commonly met with among English students, nor is its absence to be imputed to any one as a crime or a fault. The love of display is not congenial to well-bred English gentlemen;—they shrink from the public stare whenever they can avoid it, though they can face it bravely when enjoined to do so by their duty to themselves.

It is, besides, very much a question with us, how far the preparation for, and the submitting to, such an ordeal, can be serviceable in the way of discipline for entering the profession. Our idea is, that such a course would materially tend to alter the character of young medical men in this country: it is to be feared we should have, instead of the steady respectable aspirant to practice, a race of young practitioners full of self-sufficiency, pertness, and conceit. We should at least have two distinct orders of junior men: those who, with a plentiful stock of assurance — seldom the concomitant of intelligence and ability—have passed their public ordeal with success, and are constituted thereby a very important set of personages, high in their own estimation, and no doubt making a favourable impression on the undiscriminating, undiscerning portion of the public; and secondly, those, forming by far the larger class, who, with modest merit alone for their portion, pass respectably, perhaps, their public trials, yet would enter on their professional duties with a feeling of self-abasement (owing to the embarrassment experienced from the public gaze), which probably would not wear off for many a year. Thus, by such an arrangement, a stumbling-block would be placed on the threshold of the profession, which the rattle-brained, probably, would be very well able to surmount, or at least lose nothing in attempting it; while their more sober and more competent companions would be much incommoded, or perhaps deterred altogether from further proceeding.

But this sort of public examination for diplomas is not only uncongenial with the habits of the English student, but not practised in any locality in this or any other country that we are acquainted with. The wild proposers of the scheme will probably point to their favourite *concours* (the excellent working of which we have ever and anon to bring to the no-

tice of our readers); but it is the height of ignorance and absurdity to adduce such a precedent. In France, it is true that certain students do sometimes compete by *concours*—but not for diplomas: for public situations, such as *internats* in the hospitals, and the like, public examination by *concours* must be submitted to. This, however, is wholly an optional thing; nobody is obliged to undergo such an ordeal, save those who are willing and have prepared themselves for it. The case is very different for the great mass of students, who are unambitious of public appointments, and seek only to be recognized as legitimate practitioners. They are examined as they are here, with due formality, but without the interference of a gaping and disorderly crowd.

Be it not supposed that we by any means object to a body of examiners, however large, such as may be deemed essential or requisite for the proper management of a well-conducted examination. Every aspirant about to enter into the profession of medicine ought at least to possess nerve enough to show an undaunted front before his legitimate examiners: he is a candidate for a privilege, the due exercise of which will often call upon him for the fullest display of all his energy and moral courage; and it were ill-becoming in him who seeks to be placed in a capacity which, he knows not how soon, may be attended with circumstances of a trying or dangerous nature, to shrink from the scrutiny of a board of seniors regularly appointed to test his merits. We would even have the observances and ceremonials of such a trial, in every case, complied with to the letter. But all this is very different from countenancing an idle display, at once embarrassing both to judges and candidates: the admission of the public, we are persuaded, on such occasions, would be attended with no good, whatever mischief might be traceable to it. Nine-tenths of the curious auditory would, no doubt, consist of not the most industrious students, but perhaps of the idlest, and those most distinguished as scandal-mongers; and no small portion of the space allotted to the public (as if the *public*, properly so called, were at all concerned in the matter) would be occupied by those grinders and their protegés, who would have so special an interest in the proceedings.

To the latter parties, we mean more particularly the grinders, these "public examinations" would doubtless afford a rich treat — indeed, a valuable source of emolument. Every question would be stored up for future use, and every answer given by a rejected candidate—especially if he had been previously *crammed*—would be defended like an article of faith on which salvation itself depended. Woe to the examiners who should venture to exercise a discretion in plucking the pupil of a grinder! The bullying, the worrying, to which the ill-fated functionaries of such an "open" tribunal would be exposed, may readily be conceived; the game would clearly be in the hands of the greatest disturbers.

But it is the condition to which the pupil would be reduced by this newfangled system, that is most worthy of note. The reign of the grinders would be firmly established; and no pupil could venture to shew himself at a public ordeal unless he had the passport of those potent authorities. Let who would be his examiners, the grinders would be sure virtually to preside; and who would condemn more loudly those not of their flock, or defend with greater bluster those they could call their own? We happen to know one instance of this sort of abuse, practised even where the

public, or more open, examination is granted only in case of appeal. In one of the Colleges of the United Kingdom, it is the rule to grant an *appeal* trial to the candidate who demands it after his first rejection. This appeal trial is the harvest of the grinders, and they reap it too with most diligent sickles.

To the students of the metropolis, whose character is acknowledged to be not a little compromised by the doings of certain parties at the late meeting, we earnestly recommend the consideration of these things; and we trust, that should such a petition as that fabricated by the managers of the Meade-and-Wakley meeting be presented to parliament, they will protest against it in an efficient manner. The strong resolution entered into by the students of Guy's (see p. 784), together with the decided and manly part already taken by other schools, shows that there is no disposition quietly to submit to the interference of selfish and turbulent agitators. We rejoice that it is so; and we sincerely congratulate our medical brethren that there are of those who aspire to come amongst them no inconsiderable number who are willing to enrol themselves as the friends of discipline and order, and whose conduct bids fair to add both grace and dignity to the profession.

MEDICAL STUDENTS' ASSOCIATION.

The "Crown and Anchor" meeting having failed to answer the purposes for which he intended it, Mr. Wakley is now straining every nerve to get up a kind of political union among the medical students, for the ostensible purpose of watching over *their* interests, but with the real design of promoting *his own*. We earnestly advise all young men who would avoid having to regret, when too late, time misspent and opportunities neglected, firmly to resist all solicitations to join this same "Association." No legitimate object can possibly be gained by it, while there are various ways in which it may bring them into trouble, both immediately and prospectively. Indeed, it is our firm opinion that the effect of such a combination would be to lead to the introduction into the new regulations which it is expected will soon be made regarding medical education, a much more rigid system of professional discipline than has hitherto existed.

Neither let the students be so simple as to imagine that Mr. Wakley can really do anything for them; he is too well known to have the slightest influence. He is very grandiloquent, it is true, on the hustings, or when addressing the pawnbrokers and old clothesmen of Finsbury at a tavern dinner, but in the House of Commons he is a cypher—a mere nonentity. Observe: he always votes with the Ministry, yet they consult him in nothing—trust him in nothing—countenance him in nothing—no, not even by appointing him on any parliamentary committee of the slightest importance. No reference is ever made to him even regarding the affairs of the medical profession; yet he endeavours to cajole the students by pretending that he can do great things for them. Again, they are aware that there is a plan in contemplation for establishing a University in London, and that this will probably lead to great changes in the existing regulations. Well, the Chancellor of the Exchequer, who is preparing the charter, has been most assiduously courted by Mr. Wakley, who has been flattering and fawning, and kissing the dust beneath his feet, to get a sight of the intended charter, *but in vain*. This we gather from

himself; for having been thrown off his guard by vexation, he says, in his last number, "We insisted on the production of a draft of the intended instrument," but "there is no person beyond the precincts of the Privy Council Chamber who can obtain a glimpse of such a document." This speaks volumes, and shows, that whoever is admitted to the "Council Chamber," he, at least, is excluded. Let not the students, then, be deceived. Whatever is done in regard to our profession will be done by Mr. Warburton or by the Ministers, *and Mr. Wakley is not in the councils of either*. He may get up a "lark" for the students; he may swagger at the "Crown and Anchor," and emulate ancient Pistol in his Lancet; but no one, short of a regular *Johnny Newcome*, is so simple as to imagine that by such means he can carry any measure for them in Parliament.

In conclusion, we repeat our caution to young gentlemen; and we earnestly advise the parents of those whose homes are distant to lose no time in interposing and warning their sons against that distraction from their studies, and from every purpose for which they were sent to London, which cannot but result from attending Wakley's tavern exhibitions, or joining his "Medical Students' Association."

A WORD TO THE LANCET.

For some time back the Editor of the Lancet has been occupied in the most rancorous abuse of all those whom he suspects of having been, in the remotest degree, connected with the Medical Gazette; and, to give him his due, he has contrived to exhibit such lowness of cunning, such daring in falsehood, and such ruffian-like ferocity of language, as we sincerely believe to be without parallel even among the most violent conversial writers of this country. Our readers are aware, however, that we have very rarely entered on the defence of individuals attacked by the Lancet, because it appears to us that those who think its calumnies worth noticing, are themselves the proper parties to answer them. But as one expedient recently adopted has been that of attacking the *principles of this journal*, we shall so far depart from our general custom as to take a brief notice of it. We are charged, then, with maintaining that "a knowledge of the science of medicine and surgery is confined to 'hospital' physicians and 'hospital' surgeons;" and also with "*perseveringly and systematically calumniating the general practitioners of medicine in this empire*."

To this charge we answer, that it is false—grossly, malignantly, designedly false; that it is a dishonest trick practised by a cozening knave to hoodwink his readers, and to sell his pamphlet. We have stated the accusation made against us, and to our readers we say—look to the pages of our journal, and judge for yourselves whether it be true. To the author of the accusation we say—*prove* your charge, and we shall acknowledge that for once you have been just. Lay aside for one short week the habit of blinding your readers with frothy declamation, and in its stead let us have a few facts. You say we systematically calumniate general practitioners; substantiate this—show when, and where, and how we have done so. But in this, do, pri'thee, if thou canst, be honest—we ask it but for this occasion. Do not deal in insinuations and generalities, but give us special instances; and pray, when you make quotations, set down the words as you find them in the Gazette; above all, do not forge passages as heretofore, nor even alter them in your own knavish way, to suit your purpose. You see we give you good advice, and treat you very civilly; much more so, you must be conscious,

than you deserve. We offer you a fair challenge, and if you decline it, or fail in making good your charges, depend upon it, people will be very much disposed to think, as we do,—that you are no better than a trading slanderer, and that your editorial character is a blot upon the medical literature of the country.

HOW TO HAVE THE "EXAMINATION" PUBLISHED.

We have ascertained that if the gentleman recently rejected at Apothecaries' Hall, really desires to appeal against the Examiners, the straightforward course is to address a complaint to the "Court of Assistants," at whose desire alone it is consistent with the laws of the Society to disclose the grounds of refusing a license to the complainant. We have reason to believe that the Court of Examiners are most anxious that this should be done; and, if the rejected candidate be equally sincere, there can be no difficulty in ascertaining where the justice of the case lies. At the same time we think it right to hint to the gentleman above alluded to, that after the public and prominent part he has taken in this affair, if he should neglect so simple a method of proving the truth of his allegations the inference will be, that all his seeming boldness is but blustering and bravado.

We may also take the opportunity of remarking, that when we wrote the observations contained in our leader of last week we were not aware that it had been publicly stated by whom the party in question was examined. This circumstance is of importance, because it gives an application to our strictures which we did not intend. When we said that an Examiner might be "rude, or petulant, or overbearing," we did not allude to the gentleman by whom we now learn that the examination which has excited so much discussion was conducted.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, Feb. 9, 1836.

Henry Earle, Esq., F.R.S., President, in the Chair.

The first paper read this evening was, *An Account of a Case of Fracture of the Atlas*,—by B. Phillips, Esq., F.R.S.

A man, aged 32, fell from a hay-rick to the ground head foremost, the occiput coming in contact with the soil. Although stunned by the fall he was in a few minutes enabled to walk a distance of half a mile to the parish surgeon, by whom he was bled and purged. In two days he had so far shaken off the effects of the accident as to be able to follow his usual avocations. The only lesion of function which remained was an inability to rotate the head: flexion and extension of the organ were performed up to the time of his death, though the extent of these motions was, perhaps, more limited than in their natural state. Being desirous to recover the power of rotating the head, Mr. Phillips was applied to on the subject. Upon examination a small tumor was evident at the back of the neck, over the second cervical vertebra. It was apprehended that the injury might have excited inflammation in the first or second vertebra, or possibly in both, and that a modification of the articulating surface between them was in progress, which might terminate in ankylosis. He was placed on a mattress, and a dozen leeches were applied to the tumefied region every third day for above three weeks. The power of rotation was not restored, and an issue was established at the points. This was in action for six weeks without any improvement in the function: it was healed up, and a second formed. In the period whilst the second was in action he became the subject of an attack of pleurisy. This was energetically treated and cured; but in a few weeks afterwards anasarca was manifested, during the existence of which, in the twelfth month from the occurrence of the accident, he died from hydrothorax. The only other symptoms which became apparent in the progress of the case were a thickness of the voice, much like that produced by enlarged tonsils, and a slight difficulty in swallowing, which were produced mechanically, in a way which will be immediately evident.

After death it was found that the violence of the fall had produced fracture of the atlas, immediately behind its occipito-atloideal articulation. The anterior portion was carried downwards and forwards

between the pharynx and the axis, until it arrived upon the same plane with the latter organs, to the body and transverse processes of which it became attached by true bony union.

In consequence of this forcible displacement one of two things must occur; either the odontoid process, or the transverse ligaments by which it is attached to the atlas, must give way. In this case the odontoid process was fractured, and to this the patient most probably owed his life.

Several questions were put to the author by Mr. Partridge, Mr. R. Quain, and other members, respecting the precise condition of the patient in performing the functions of rotating and supporting the head, &c., which Mr. Phillips answered to the extent of his personal observation. The patient appeared to have sufficient muscular power, at least in the early part of his disorder, to support his head without the assistance of his hands.

The President mentioned some interesting cases of injuries occurring to the cervical vertebræ of children, in some of which he had reason to believe that the odontoid process was fractured, or broken off. The little patients were generally scrofulous, and met with the accident in play. It was remarkable, in one instance in particular, how tenaciously the child persisted in holding his head fixed between his hands after the occurrence of the injury; nor did he venture to desist from the practice for some days. The cure was attended with complete ankylosis. While on his legs Mr. Earle wished to call the attention of the meeting to a specimen of injured spine which he exhibited. He had bought it among other bones at the late Mr. Heaviside's sale, and it was marked as an example of diseased vertebræ; but he (Mr. Earle) was convinced it was the result of a very complicated fracture. The vertebræ belonged to that part of the spinal column where the dorsal and lumbar portions unite; and the singularity was, that the vertebral canal was in one part reduced to the calibre of a common goose-quill. Here the patient must have lived for some time with his spinal marrow compressed in an extraordinary manner. The state of the callus, and union of the fracture, shewed clearly that a considerable time must have elapsed before the death of the patient.

Mr. R. Quain cited a very interesting case, in which the ring of one of the cervical vertebræ was suddenly broken off from the body of the bone, in an elderly man. The head had to be supported by various mechanical contrivances; but the symptoms were by no means alarming. The patient even took a long journey by coach, and, in short, survived for eleven months. Mr. Quain had had an opportunity of examining him after death, when the exact nature of the injury was ascertained. No doubt but for the age of the patient, and the little precaution taken in keeping the parts together, union might have been effected.

A second paper was read,—*On a Case of Recovery from Poisoning with Opium*,—by Charles Smith, Esq.

The peculiarity in this short history was, that the patient was sinking fast into death, under the influence of the narcotic poison, when artificial respiration was had recourse to. The effect was striking: the heart's action and the energy of the circulation were restored, and the person soon completely recovered. No bellows had been used in the process of inflating the lungs, but a simple tube was introduced into the nostril, keeping the other closed at the same time.

Dr. J. Johnson thought that the case was valuable, inasmuch as it showed how beneficially so very simple a mode of inflating the lungs might be employed.

The President mentioned an instance in which a patient, sinking under the effects of a strong tobacco injection, administered with a view to the reduction of a strangulated hernia, was revived by insufflation, and artificial respiration, managed with a pair of bellows.—Adjourned.

LECTURE ON CORNS AND BUNIONS,

Delivered in the Theatre of St. George's Hospital, January 19, 1836,

By Sir Benjamin C. Brodie, Bart.

It cannot be doubted that the physical condition of man is, on the whole, much improved by civilization; but it is not so in all respects, and the usages of society are productive of some evil, combined with much good. The evil affects the weaker more than it does the stronger sex; and among the former, those who belong to, what are called the higher classes, suffer more than those who belong to the lower. Young ladies, living much in heated rooms, taking little exercise in the fresh air, over-educated as to the acquirement of accomplishments, and using their muscles too little, lose the beautiful figure with which they were endowed by nature, and become afflicted with curvatures of the

spine, and weakness and distortion of the ankles. The same mode of life renders them liable to the innumerable varieties of hysterical disease, which in so many instances destroy the whole comfort, and I may say the dignity, of existence, enervating both the body and the mind, and making their condition altogether much less desirable than that of the poor peasant girl.

There is another order of diseases which we meet with more frequently among females of the higher classes than among other persons—namely, corns and bunions; and it is to this last humble, but not unimportant subject, that I propose to call your attention in the present lecture.

A corn is in the first instance a thickening of the cuticle. Whenever the cutis is habitually subjected to the influence of pressure, it secretes a thick and horny cuticle. We find examples of this in the hands of many mechanics, and in the soles of the feet in those who walk much. But every thickening of the cuticle is not a corn, and this name is applicable only to those cases in which the cuticle is thickened over a projecting portion of bone, on which the pressure is, as it were, concentrated. Corns may occur in any part of the body in which this combination of circumstances exists; but, for obvious reasons, they are met with in the feet much more commonly than any where else.

If shoes were constructed of the shape of the human foot, neither too large nor too small, and making an equal pressure every where, corns and bunions of the feet would never exist. But, unfortunately, shoes are seldom made after this fashion, and in ladies' shoes especially there are generally two signal defects: first, the extremity of the shoe is much too narrow for that part of the foot (namely, the toes) which it is to contain; and, secondly, for the purpose of displaying as much of the foot as possible, the whole of the tarsus and metatarsus is left uncovered, and the pressure of the shoe in front is thrown entirely upon the toes. The toes are thus first squeezed against each other, and then pushed out of their natural position; and all the projecting points, chiefly where the joints are situated, are pinched and tormented either by the neighbouring toes or by the leather of the shoe, and thus it is that corns of the feet are generated.

In order that you should understand the precise situations in which corns are most likely to take place, you must consider more particularly the effects, which the pressure of the shoe produces on the toes. The little toe is pushed from its parallel position, so that it is in fact underneath the fourth or adjoining toe, and corns are generated on its outer surface over the prominences of its joints. A corn is also frequently met with in the angle between the little toe and the next toe, where the first phalanx of the former is pressed against the head of the metatarsal bone supporting the latter. Sometimes the consequence of wearing a very narrow shoe is, that one of the toes (and it is generally the second or fore-toe) is pushed upwards, so that it lies over the two adjoining toes, that is, over the great toe and the third toe, the extremities of which come in contact underneath; then the leather of the shoe is drawn tight over the upper surface of the second or displaced toe, and corns are produced over one or more of its articulations. At other times one of the toes (and in this case also it is generally the second toe) is displaced in another way. The extremity of it is pushed downwards, so that it lies beneath the extremities of the two adjoining toes, which come in contact over it. But this change cannot take place while the three phalanges of the displaced toe remain in a line with each other. The first and second phalanx make an angle, projecting upwards. The second joint of the toe becomes prominent above, and a corn is formed over it. If the shoe, instead of being too narrow, be too short, for the foot which it contains, the last phalanges of all the smaller toes are kept constantly in a half-bent state, and a row of corns is generated, one being situated on the upper part of the last joint of each of these toes. I have endeavoured to enumerate what may be regarded as the most ordinary localities of corns; but of course they may be produced any where else, according to the shape of the shoe, the mode of walking, and other circumstances.

I have said that a corn is, in the first instance, a thickening of the cuticle secreted by the cutis, when it is kept in a state of constant irritation by the operation of external pressure squeezing it against a prominent surface of a bone. But a complete corn is more than this. A bursa, or bag of synovial membrane, similar to those bursæ which are of original formation, but of a very small size, is formed between the thickened cuticle and the cutis; and it is this combination of thickened cuticle, with a subjacent bursa, which constitutes a perfect corn. This is a fact which you may easily verify for yourselves, as the opportunities of dissecting corns are abundant in the dead house of the hospital.

The thickened cuticle of those corns, which are situated externally, becomes dry, and hard, and horny; while that of the corns which are situated between the toes remains soft, and to a certain degree moist; and this gives rise to the distinction between hard and soft corns. I shall speak

to you of hard corns first,—of soft corns afterwards.

A hard corn, when it begins to be formed, is productive of no other inconvenience than of a slight degree of pain and tenderness after much exercise. The pain and tenderness increase, so that the patient in the evening is glad to take off the leathern shoe, and put on a large slipper. Then the whole foot, after exercise, is hot and uneasy. These symptoms subside with rest, and the absence of pressure, during the night, but return with the wearing of the shoe and exercise during the day. By and bye the bursa under the horny cuticle becomes inflamed, and distended with fluid, and the pain is much aggravated. But the sufferings are greatest in those cases in which the bursa suppurates. An abscess forms in parts which are incapable of distention, and you know how much mischief even a very small collection of pus, under such circumstances, may occasion. I was sent for to an old gentleman who was suffering excruciating pain in the whole foot, which was red, and much swollen, the swelling extending up the leg considerably above the ankle. In one toe, and in the neighbouring part of the foot, the tenderness and other marks of inflammation were greatest, and here I discovered an old neglected corn. He could scarcely bear the corn to be touched; however, I carefully removed the hard cuticle with a scalpel, and made an opening into the bursa under it. Not more than a drop of matter escaped, but this was sufficient to give immediate relief. On the following day he was well. I was desired to see another patient, a young lady, under the same circumstances, except that the symptoms were more severe. The inflammation involved nearly the whole leg, and there was a frequent pulse, and much general excitement. I removed the thickened cuticle of a corn on one of the toes, and allowed a very small quantity of pus to escape which was collected beneath it. This gave immediate relief, and on the following day she was all but well. Several similar cases have fallen under my observation.

I have already mentioned that the most common seat of a soft corn is in the angle between the little toe and the fourth toe, over the head of the metatarsal bone which supports the latter. Occasionally, however, a soft corn occurs elsewhere—as, for example, on the inside of the little toe, opposite to the last joint of the fourth toe. Such corns are even more painful than hard cones, except when suppuration takes place in the bursa, and then the suffering is less in proportion, as the thickened cuticle of a soft corn admits of distention more easily than that of a hard corn.

Under ordinary circumstances, it is easy to give temporary relief to a patient who suffers inconvenience from a hard corn. The thickened cuticle should be removed, so as to lessen the pressure on the parts below; and this may be accomplished in various ways. *First:* If the corn be of long standing, and a piece of linen or thin leather, spread with some mild plaster (diachylon for example), be applied, and worn over it, it will sometimes exfoliate or separate without further trouble. *Secondly:* The corn may be rubbed with the nitrate of silver, or (which is indeed preferable) the concentrated nitric acid may be applied by means of a probe armed with lint. The texture of the cuticle being thus destroyed, exfoliation will take place, so that in the course of a few days the corn may be readily peeled off. *Thirdly:* The corn may be reduced in thickness by scraping its surface with a very fine steel or fish-skin rasp. And, *fourthly:* The corn may be removed by means of a fine cutting instrument. This last is the shortest and simplest method; and the patient may keep himself in a state of comfort by procuring the assistance of a dexterous chiropodist at stated periods, who will perform this operation for him better than he can perform it for himself.

With a view to a permanent cure, however, it is necessary to have recourse to other methods of treatment. In some way or other all undue pressure must be removed from the part on which the corn is situated. *First*, the shoe must be made as nearly as possible to the shape of the foot, and it must cover the metatarsus and a portion of the tarsus, so that the whole pressure may not be thrown on the toes; or a boot made to be laced or buttoned may be worn instead of a shoe. In some cases it is advisable that the shoe or boot should be made, not of ordinary leather, but of very soft and flexible buckskin, or of cloth. A material for shoes and boots is sold under the grandiloquent name of *pannus corium*, which answers the purpose intended in these cases very well. It is really a kind of cloth, but it has the appearance of leather, and is very soft and pliable. *Secondly*, if any of the toes are displaced in any of the ways which I have before described, we must endeavour to restore them to their natural position. In young persons this may be generally accomplished. A contrivance made use of by the bandage makers is very useful on these occasions. It consists of a thin plate of metal covered with thin leather, or a piece of strong leather, fitted to the lower surface of the foot,—not to the whole of the surface, but extending from the extremities of the toes nearly to the tarsus. Slits are formed in this plate of metal or leather,

and tapes are passed through these slits, forming loops above, by means of which the toes are bound down and retained in their proper places. In many cases the same object may be attained by simpler means. A stripe of linen, spread with adhesive plaster, about two-thirds of an inch in breadth, may be passed over the toes which are too elevated, and under the others, the extremities of the plaster being made to cross each other over the metatarsus. If this be neatly applied, it will keep the toes parallel to, and on the same level with, each other. Whichever of these methods be employed, it is necessary that it should be persevered in for a considerable time. In older persons, in whom the toes have been long displaced, they have sometimes become so adapted to their unnatural position, that it is almost needless to attempt to alter it. Under such circumstances we are sometimes compelled, in hospital practice, even to amputate one of the toes, in order that the patient may not be disabled from gaining his livelihood; and this may be occasionally necessary even in private practice. A young lady of rank suffered from a displacement and a distortion of the second toe, such as I have already described. The extremity of it lay under the extremities of the two adjoining toes; the second and third phalanges were nearly anchylosed at a right angle to each other, and a corn was formed on the second joint, where it made a considerable projection above. She applied to me to amputate this offending toe. I answered, " that I would do no such thing; that I might do it for a labouring person, but that her case was entirely different, as she had not to earn her livelihood by her bodily labour." She replied, " You seem to treat the matter very lightly, but this toe and corn make my life miserable: I can take no exercise, I am unfitted for society, and I have tried all other methods of relief without success." On inquiry, I was satisfied that she in no degree exaggerated her sufferings, and I therefore complied with her wishes, and amputated the toe at its first joint..

A very simple, but scientific, method of relieving, and indeed of curing, corns is practised by the chiropodists. A piece of buck-skin leather, spread with some adhesive plaster, is applied on the toe on which the corn is situated, there being a hole in the leather corresponding to the corn. Thus the pressure of the shoe is taken off the corn, and thrown on the surrounding parts. If this be kept constantly applied, and proper shoes be worn at the same time, the corn will gradually disappear.

In some cases a hard corn is formed on the lower surface of the foot, over the head of one of the metatarsal bones. A corn in this situation is especially troublesome, rendering the patient absolutely lame; but it may be relieved or cured by the method which I have just explained, only one slight modification of it being required. The hard cuticle being removed, a broad piece of buck-skin leather is to be applied, having a hole in it where the corn is situated. But a thin piece of calico spread with adhesive plaster, and having no hole in it, is to be applied first; that is, between the leather and the foot. Without this last contrivance the flesh of the foot, when the patient walks, bulges or projects into the hole of the leather, so as completely to fill it up, and the patient's condition is rendered rather worse than better. The calico with adhesive plaster prevents this inconvenience, at the same time that it does not prevent the leather answering the intended purpose of taking the pressure off the corn, and throwing it on the surrounding parts. I may observe, by the way, that the same method is applicable to some other affections of the lower surface of the foot, as well as to corns.

When abscess is formed in the bursa under a hard corn, the treatment to be employed is very simple, although the relief it affords is immediate and great. You are to pare off the hard and thick cuticle, and open into the bursa, so as to allow the small quantity of pus which it contains to escape. Thus the corn is effectually destroyed, both the cuticle and the bursa; and it is very easy, by means of the expedients which I have just recommended, to prevent it being regenerated.

The treatment of soft corns is to be conducted on the same principle with that of hard corns; some modification of it only being required, on account of their peculiar texture and situation. The thickened cuticle may be removed by means of the concentrated nitric acid, applied so as to penetrate into its substance, but not to the parts beneath. This destroys its texture, causing it to become dry and shrivelled; and in the course of a few days it begins to exfoliate, and is then readily peeled off. If an abscess forms in the bursa of a soft corn, it should be treated in the same manner as that in the bursa of a hard corn.

In some cases, even though there be no abscess underneath, a soft corn becomes exquisitely sensitive, so that the patient cannot bear it to be even touched; and he is made as lame as if he suffered from the gout or any other painful malady. Such a case fell lately under my observation, which I mention, not because it was peculiar, but because the sufferings of the patient were unusually severe. There was a broad soft corn on the side of one toe,

where it came in contact with the side of the adjoining toe, and not in the angle between them. The patient could scarcely walk, even with a loose slipper, and the corn itself was so exquisitely sensitive, that the slightest touch could not be borne. This state of things had existed for many weeks, the corn itself being of a much earlier date. I applied the strong nitric acid until I had reason to believe that it must have penetrated through the thickened cuticle. An increase of pain followed the application, and continued for some hours. On the following day there was a manifest improvement. I was now enabled, without any difficulty, to remove the corn with a fine scalpel. The recovery of the patient was immediate and complete, so that, having been previously quite lame, he was enabled in less than twenty hours to walk as well as ever.

The first thing to be done for the permanent cure of a soft corn is, that the patient should be provided with a shoe of a proper shape, and that the toes which are in any way displaced should be brought back into their proper position. Now I have already observed that the most common situation of a soft corn is between the fourth toe and the little toe, over the head of the fourth metatarsal bone, and that in this case the little toe, towards its extremity, is always pushed more or less underneath the second phalanx of its neighbour. You will sometimes succeed in bringing the little toe to its proper place by means of a stripe of adhesive plaster, applied round it in the manner of a loop, and then encircling the foot.

In other cases you will find the following method more convenient than that which I have just described:—A piece of *very thick* buck-skin leather, spread with adhesive plaster, is to be applied on the inside of the little toe, so as to occupy the whole of the inner surface, from the apex to the second joint. The leather should be cut so as to be thin at its margin; and it should be sufficiently broad to admit of being doubled over a good part of the upper and under surface of the toe, as well as its extremity. This contrivance will keep the little toe at some distance from the next toe, and prevent it from sliding again under it. If both of these expedients fail, the patient must be content to wear for a time the metallic or leathern plate, with loops of tape for inclosing the toes, which I have already described.

The bunion which is frequently formed on the inside of the ball (as it is called) of the great toe, differs in some respects from the disease of which I have hitherto spoken.

The great toe ought to be in a line with the metatarsal bone, by which it is supported. But a shoe which is too narrow at its extremity, causes it to incline towards the outside, displacing, in a greater or less degree, the toe next to it, as I have explained already. In some cases, the effect of pressure on the great toe is actually to alter the position of the joint between it and the metatarsal bone; a portion of the articulating surface on the extremity of the latter being absorbed, and a new articulating surface being made to supply its place more externally than the old one. The existence of these changes I have ascertained by dissection. Now, the consequence of all this is, that the head of the metatarsal bone makes an unnatural prominence, and is more acted on by the pressure of the shoe than it would be otherwise. The cuticle becomes thickened, not at one particular point, but over a considerable surface, and underneath the skin a large and very distinct bursa is generated between it and the bone. The difference between what I have now described and a common corn, may reasonably be attributed to the large size of the head of the first metatarsal bone, and to the consequent diffusion of the pressure over a broad surface.

When a bunion is once formed, the bursa belonging to it is liable to become inflamed after any unusual degree of exercise, or on it being subjected to the pressure of a more than commonly tight shoe. Serum is then effused into the cavity of the bursa; the swelling is much increased, and it becomes at the same time exquisitely painful and tender. If the patient remains at rest, the inflammation subsides, the serum effused into the bursa becomes absorbed, and the additional swelling disappears without any further ill consequences. If, however, he continues to walk about, wearing at the same time a tight shoe, the inflammation proceeds further; suppuration takes place, and an abscess is formed. Such an abscess is slow in reaching the surface, and the patient generally suffers severely before it bursts externally; and when it has burst, as the synovial membrane of the bursa granulates with difficulty, the healing of the abscess is very tedious, the parts remaining all the time in a very irritable and painful state.

For the relief of this bunion, when it is free from inflammation, or inflamed only in a slight degree, the following plan of treatment should be adopted:—The patient should be provided with a shoe of sufficient dimensions, of a proper shape, and made of cloth or a soft and pliant leather. A piece of thin calico, spread with diachylon plaster, should be applied over the bunion, covering also some of the surrounding

parts; and over this he should wear a piece of thick buckskin leather, spread with adhesive plaster, and having a hole in it, corresponding in size and figure to the bunion from which it is intended to remove the pressure. If the bursa be much inflamed, the patient should be confined to the couch, without a shoe: leeches may be applied in the neighbourhood, and warm fomentations may be employed also. If an abscess be formed, it should be freely opened with a lancet. For some time after the abscess has been opened, no other treatment is required than the application of a poultice, which may be changed afterwards for calamine cerate, or some other simple dressing. Perhaps the abscess may now gradually heal, and no other treatment may be required; otherwise it will be necessary to destroy the inner secreting surface of the bursa by means of some kind of caustic. The concentrated nitric answers this purpose very well. The end of a dressing-probe may be armed with lint, then dipped in the acid, and applied for a few seconds to the internal surface of the bursa. A thin slough will, of course, be formed, on the separation of which it may reasonably be expected that the remains of the bursa will contract and granulate: otherwise the application of the caustic must be repeated.

After what I have already said, it is needless for me to trouble you with any observations as to the means which should be adopted for the purpose of preventing the bunion being regenerated.

A case came lately under my observation, in which what appeared like a bunion on the inside of the ball of the great toe contained an albuminous substance, of the consistence of the vitreous humor of the eye, similar to that which is found in the ganglions, which occur in the neighbourhood of the wrist and in some other situations. Whether this was an ordinary bunion, in which the vessels of the bursa secreted this peculiar substance, or whether it was really a ganglion, I was unable to determine. The treatment which I adopted was that of opening the cyst freely, and applying the concentrated nitric acid to its inner surface. It was necessary to do this with some caution, lest I should injure the joint or bone underneath; and therefore several applications of the acid were required. My object was to destroy the secreting surface, and obtain a granulating surface in its place; and when I last saw the patient, previously to her returning to the country, I had reason to believe that I had succeeded: but I have not heard of her since.

A tumor is occasionally formed on the instep, which, though not exactly a corn, bears a near relation to it. It is met with in young men who wear tight boots, and the usual situation of it is over the articulation, between the internal cuneiform bone and the metatarsal bone of the great toe. The tumor is under the skin, hard and immoveable, so that it seems to a superficial observer to be an enlargement of the bone itself. The skin over it is in a natural state, except in cases of long standing, in which the cuticle becomes somewhat thickened. I have had no opportunity of dissecting the parts affected with this disease, and am uncertain, therefore, whether it be formed in the ligaments of the joint or periosteum, or in the ultimate fibres of the tendon of the tibialis anticus muscle, or in what other texture.

Such a tumor is productive to the patient of as much inconvenience as a corn, and it requires the same kind of treatment. He should, for a time, leave off boots altogether; or if he cannot do this, the boot-maker should be directed to provide a last with a projection in that part of it which corresponds to the situation of the tumor, so that the boot may not exercise any pressure on it. A piece of thick buck-skin leather, with a hole in it to receive the tumor, will also give the patient immediate relief, and ultimately effect a cure: but the cure, of course, will not be permanent, if he continues to wear tight boots afterwards.

I have seen a tumor apparently similar to that I have now described, in school-boys, situated over the head of the tibia, at the insertion of the tendon of the extensor muscles, commonly called the ligament of the patella, and apparently the result of kneeling, or clambering on the knees: and a tumor of the same kind is sometimes met with on the inner condyle of the femur in those who ride much on horse-back. In either case the avoiding pressure is sufficient to relieve the patient of all the inconvenience which the disease produces. I have known cases, however, in which there have been some remains of a tumor over the head of a boy's tibia ever afterwards.

EXTRACTS

FROM

DR. ASHWELL'S REPORTS OF OBSTETRIC CASES.

Amenorrhœa.—There have been seventeen cases of this affection. We might designate eleven of them as simple amenor-

rhœa; two as occurring in highly-vascular plethoric habits; and the remaining four as associated with great constitutional debility. The treatment pursued in the first-mentioned cases was variously modified. In one instance leeches were applied within the vulva, at the time when lumbar pain, with other symptoms of uterine irritation, indicated a natural effort for the establishment of the catamenia. After the second application the secretion appeared. In several cases an injection of the liq. ammoniæ and milk, in the proportions of ♏x. of the former to ℥j. of the latter, was employed. This proved in some instances highly efficacious, while in others it failed. The two plethoric females were bled locally and generally; and this, associated with the full operation of purgative medicines, completed their cure. Tonics and emmenagogues were the remedial agents for those in whom constitutional weakness was predominant. The metallic tonics, such as the iron and zinc, were preferred.

Dysmenorrhœa.—Five of these cases occurred in females of diminished constitutional power; and one was associated with a robust plethoric diathesis. In those cases wherein false membranes were thrown off, and which were attended with a scanty secretion of the catamenia, the pain preceded the discharge. In one instance, while the pain lasted, the discharge was more abundant than natural, and was mixed with coagula, evidencing its menorrhagic character. In one case the pain supervened on the cessation of the catamenial period; while in another, this affection was complicated with epileptic fits. These fits, which came on about ten days after her admission, were preceded by an *aura*, which appeared to arise from the sacrum. A moxa was applied over the spot; the effect of which was an immediate abatement of the fits, and subsequent recovery from them. A proneness to abort characterized another case. The treatment pursued with these patients varied with their several peculiarities. In all, however, two great points were kept in view; viz. 1. To alleviate the pain during the menstrual period; and, 2. To regulate the general health during the intervals. To fulfil the first indication, opium, combined with camphor, hyoscyamus, ipecacuanha, and conium, were ordered: while the second was answered by the use of the metallic tonics, especially iron and zinc.

Chlorosis.—Examples of simple, confirmed, and complicated chlorosis were met with in these cases. Purgatives, tonics, and emmenagogues, were severally employed; proportioning their amount, character, combination, and time of employment, to the peculiar features of the case. The iodide of iron, as a remedial agent in this affection, deserves especial mention; its exhibition has been attended with the most marked success, particularly when glandular enlargements, and other indications of a strumous habit, have been associated with this disturbance of the health. It should at first be given twice a day, in two grain doses, suspended in any vehicle which does not possess tannin or other astringent matter. The iodide of iron may, in some constitutions, occasion headache, vertigo, nausea, heat, and a sensation of weight in the hypogastrium; which symptoms may be removed by taking the carbonate of magnesia at night, by the suspension of the medicine, or even by diminishing the dose.

Irritable uterus.—Pain in the lower abdomen, shooting into the loins, and coursing the brim of the pelvis, aggravated by the erect, and mitigated by the sedentary or recumbent position, attended these cases. In some instances the pain was increased before, in others after, menstruation. An internal examination detected the exquisite sensibility of the uterus. The first indication in the treatment was, to relieve the pain; the second, to improve the constitutional power. The recumbent position rigidly enforced—the local abstraction of blood from the loins or vulva—camphor, hyoscyamus, and poppy, in combination—the injections of poppy—fomentation, with the frequent use of the hip-bath, answered the first indication. In one case permanent relief was obtained by the application of a moxa over the sacral region. The constitutional treatment comprised the exhibition of tonics, bitters, &c. The iodide of iron was thought the most useful. The bowels were kept regular by a mixture of salts and magnesia.

Leucorrhœa.—These cases were confined to women of feeble constitutional power, and occurred mostly in young unmarried females. They were carefully distinguished from cases of inflammation of the os and cervix, by testing the discharge, which invariably resisted admixture with water. Neither was the leucorrhœa the effect of structural lesion, nor a symptom of displacement of the uterus; but the result of constitutional debility, not unfrequently associated with catamenial derangement. The symptoms present were, pain in the back, pale surface, a tendency to œdema, impaired appetite, susceptibility of fatigue, breathlessness, with more or less hysteria, &c. The remedial plan consisted in the administration of tonics internally, with local astringent injections. The quinine, cinchona, gentian,

calumba, were the principal vegetable, the zinc and iron the principal mineral tonics. The efficacy, however, of the secale cornutum, in these cases, demands especial notice. An injection composed of a strong decoction of the secale, with the addition of some nitrate of silver, proved very serviceable; while its internal administration, in five-grain doses, made into a pill with confect. rosæ, was attended with marked success.

Menorrhagia.—Under this term are comprised only those ca es in which the menstrual secretion is mixed with a discharge of pure blood. The number of cases afforded examples both of the active and passive menorrhagia: the former were recognised by symptoms of plethora, such as a sense of fulness and throbbing, with a feeling of heat and weight about the pelvis, and a pungent sensation about the pudenda; the mammæ became tumid, painful, and hot, and the pulse accelerated; the discharge, too, varied in its mode of escape; sometimes it flowed abundantly, causing faintishness, and even syncope; at others it proceeded more slowly, forming coagula within the vagina: these acted as a barrier, preventing the further flow, and were eventually expelled by voluntary efforts. Bleeding, both local and general; refrigerants, such as nitre, with digitalis, and other remedies calculated to obviate excessive vascular action, were employed in these cases. The instances of passive menorrhagia were by far the most frequent, occurring in both married and single women. The secale cornutum proved very valuable in arresting the flow, by its specific action on the uterus. The sulphate of zinc was exhibited internally, as a tonic, in the absence of the catamenia.—*Guy's Hospital Reports.*

NEW ELECTRO-CHEMICAL APPARATUS.

M. Becquerel, of Paris, has introduced to the notice of the scientific world, a modification of the Electro-chemical Battery, which reduces it to a striking simplicity. And yet he finds that all bodies exposed to it are either decomposed or attacked, exactly as if they were submitted to the voltaic pile; that its power of action continues uninterruptedly; and that the intensity of its current is not affected, in any appreciable quantity, by the causes which tend to weaken the electro-chemical effects of the pile.

Simple as M. Becquerel's apparatus is, its arrangement has already been improved by M. Aimé, who describes the newer instrument as follows:—A U-formed tube, pierced with a small hole at its lowest part, is to have its legs half filled with very fine sand. One of the legs is then to be filled up with diluted sulphuric acid, and the other with a concentrated solution of sea-salt. The two fluids will descend through the sand, and combine at the lower part of the tube. As soon as this combination is effected, the fluid, resulting from the combination, escapes immediately through the hole, which is loosely plugged with a bit of asbestos to prevent the escape of the sand. A slip of platina is dipped into each leg, and wires from these slips connect them with a galvanometer. On making contact, the needle immediately indicates, by the change in its direction, the formation of the current produced by the action of the two fluids on each other. The intensity of this current varies with the degree of concentration of the solutions, and with the rate at which the combination is made: to facilitate the latter, the size of the hole may be increased.

When a constant and regulated supply of the solutions, and a proportionate discharge of them, after they are combined, are obtained, the process can be carried on for any desired period without intermission. There is, however, one precaution necessary,—the solutions must be so prepared and proportioned, that they shall not, on combining, form a salt and obstruct the discharge. From the experiments of M. Becquerel and M. Aimé, there seems already ground for believing, that electro-chemical currents of determined intensity may be produced and maintained during whatever time may be necessary to effect chemical decomposition, by this powerful agent.—*Magazine of Popular Science*, No. 1.

SAFETY IN THE MINES.

The high character bestowed on Upton and Roberts's lamp by the Parliamentary Committee last session, has induced most of the mine-owners throughout the kingdom to give the instrument a trial; and nothing can be stronger than the certificates by which they attest its complete efficacy. From a letter, dated Cophall Colliery, 10th December, 1835, the following passage may be quoted:—"A double-gauze Davy lamp and Upton and Roberts's new safety-lamp, were both taken in our presence to a blower of gas, the aperture $2\frac{1}{2}$ inches in diameter, and placed a short distance from it. The Davy instantly filled with flame, the action of which appeared so violent, that it was considered necessary to withdraw it as speedily as possible, to

prevent explosion; while the new lamp was of itself extinguished. On relighting the latter, and placing it farther from the mouth of the blower, it was found to burn, but show the presence of the inflammable gas by the light of the flame, which was about the thickness of the little finger, and smoky at top; at the same time the Davy-lamp, which was held in the headway, quite out of the stream of the blower, filled with flame, so that it again appeared necessary to remove it from its situation." Another letter to the same effect, dated from Dudley, is signed by about fifty proprietors, who had witnessed the experiments, and were anxious to record the satisfaction they experienced at the results.

SIXTH EDITION OF A DENOUNCED NOTORIOUS MEDICAL WORK.

To the Editor of the Medical Gazette.

SIR,

ON the advertising sheet of a new and respectable journal, is the announcement of "Mr. Lawrence's Lectures on Physiology, Zoology, and the Natural History of Man, reprinted *verbatim* from the original edition, suppressed by the Author;" to which advertisement is annexed a paragraph, sneering at the clergy, whose "hatred he encountered;" at the Governors of Bethlem Hospital, whose "resentment" he incurred; and at the decision of Lord Eldon, "who refused him a right of property in them:" in consequence of which these Lectures have become "public property." "They have already reached a sixth edition!" It furthermore states that "Mr. Lawrence was a materialist when these lectures were delivered!"

With the honour of the publisher who can seize on property so confiscated, or with the moral honesty of the man who can plunder his fallen brother and rob him of the only gains of their mutual unhallowed craft, I have nothing to do. May those stings of conscience find him out *in time*, which can paint to his reckless imagination, in its true colour, the *cruelty* he has inflicted on the youth to whom he has sold the whole of his six editions.

But, sir, with Mr. Lawrence, as a public teacher, I have thus to do: *I* ought to *know*—and all who, like myself, send yearly young men to London, are bound to ascertain, into whose hands they are to commit them—whether by the open avowal of atheism, or by the more specious garb of materialism, or of scepticism, we are to find those principles of religion in which our pupils or our children have been instructed, are to be destroyed or disturbed.

May I venture to hope, through *your* agency (believing you to be a watchful guardian of our professional character, and, I trust, not less so of those Christian and moral principles which alone give lustre to our profession), that your power will be exerted to repress the sale of this publication; and may I venture to hope that Mr. Lawrence will himself stand forth and deny that this work is edited under his sanction; that he will denounce those writings as the early phantoms of his ardent and highly-gifted mind, which sober reflection and calm inquiry has induced him to recal, and show that he has suppressed them at the bidding of his own conviction, rather than the fear of public censure, and thereby the loss of public favour and support.—I am, sir,

Your obedient servant,

W. J. WICKHAM.

Winchester, Feb. 2, 1836.

FEELING IN RESPECT TO PUBLIC EXAMINATIONS.

To the Editor of the Medical Gazette.

SIR,

FROM an extensive intercourse with pupils belonging to various medical schools in London, I have had frequent opportunities of learning the sentiments of many regarding the plan of a "public examination," so much agitated of late by your notoriety-seeking contemporary, and I assure you that I have found a great majority of young men decidedly hostile to it: they have generally expressed it as their opinion that "rejections" would be much more frequent than they are at present, if it were adopted. It is devoutly to be hoped, sir, that you, who have always shown yourself the true and disinterested friend of the student, will not abate your powerful advocacy of their cause and true interests in the present instance, when it will be so valuable to them; and I have no doubt that by the instrumentality of your able and respectable journal,—which has always proved itself an antidote to the pernicious influence of the Lancet,—the minds of the few young men who have been led into error by that publication, will be disabused. A public examination, as a *dernier ressort* in case of alleged grievance, would by the medical students generally be received favourably.—I remain, sir,

Yours respectfully,

A BOROUGH STUDENT.

February 5, 1836.

PROTEST OF THE STUDENTS OF GUY'S HOSPITAL,

AGAINST THE LATE PROCEEDINGS AT THE CROWN AND ANCHOR.

To the Editor of the Medical Gazette.

SIR,

We have great pleasure in transmitting to you a list of those gentlemen, constituting a large majority of the students of Guy's Hospital, who have entered their protest against the *ill-judged* and *violent proceedings* of the meeting at the Crown and Anchor Tavern, held January 18th, 1836; in which certain resolutions were carried and agreed to, as if emanating from the *general body* of the *medical students in London*, which were in their nature *ill advised*, and in the manner of the whole proceeding characterized throughout by *party violence*.

We are, sir,

Your very obedient servants,

H. C. MUGG,
J. BENT.

Guy's Hospital, Feb. 9, 1836.

"The undersigned have perceived, with much surprise and regret, that at a meeting, which was held at the Crown and Anchor Tavern, on the 18th of January, 1836, certain resolutions were proposed and carried, as if emanating from the general body of medical students in London, which were in their nature ill-advised, and in the manner of the whole proceeding characterized by party violence. They desire, as students of Guy's, to disclaim all participation in the transaction, and wish it to be distinctly understood that they do not agree in the resolutions above referred to."

Signed by *Ninety-four* students.

[The original document, with the autograph signatures, is before us, but we regret we have not room to give the names at length.—ED. GAZ.]

PROFESSOR GEIGER.

WE learn from the German journals, that Dr. P. L. GEIGER, of Heidelberg, died on the 19th of last month, in the 48th year of his age. His name is well known in connexion with pharmacy: his *Journal* has had an extended celebrity, and his excellent *Handbuch der Pharmacie* has gone through several editions.

NEW MEDICAL WORKS.

LECTURES
ON
MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XXI.

INORGANIC MATERIA MEDICA.

IN this lecture, gentlemen, I have to examine those articles of the materia medica which are derived from the inorganized kingdom; which, however, cannot be denominated minerals, since most of them are products of art.

In the first place, let us fix on the most appropriate methods of arranging them. You are aware I purpose adhering, as much as possible, to a natural-historical order; but we have now to notice a class of substances for the most part not natural bodies. Let us inquire, therefore, what methods the mineralogist adopts in the classification of the objects of his study, and thereby determine whether the inorganic materia medica can be arranged on a similar plan.

Karsten, Haüy, Berzelius, Leonhard, Alexander Brongniart, Beudant, and Thomson, have arranged minerals according to their *chemical* properties. Mohs, on the other hand, formed a classification in which all chemical properties are purposely excluded, and *crystallographical* characters principally relied on: this he denominated a natural-historical method. Now all systems founded on principles so exclusive as this, have always appeared to me highly objectionable. Why should a naturalist not employ any properties of a body by which he can characterize it? If the zoologist and botanist have not hitherto resorted to chemical characteristics, it arises in a great measure from chemistry being unable to give much assistance in distinguishing animals and vegetables. In mineralogy, on the other hand, chemical properties are of essential service, and, therefore, I conceive ought to be employed, though not to the exclusion of assistance derivable from physical characters. Werner, and, more recently, Necker, have made use of both classes of properties.

You see that a considerable number of mineralogical writers have employed chemical properties, either partially or wholly, in their arrangements and classifications: you will not, therefore, be surprised at my selecting these for the basis of the order in which I shall discuss the articles of the inorganic materia medica, more particularly as the order followed by Mohs is inapplicable to them. These articles I shall arrange in four classes, thus:—

Class the first will contain an account of the Elementary non-metallic substances.

Class the second, the non-metallic inorganic Acids.

Class the third, Water.

Class the fourth, Metals, and their compounds.

Before, however, I proceed to discuss the individual substances of these classes, I must offer a few remarks respecting crystalline forms, since, in speaking of the salts, I shall frequently have occasion to employ terms used in crystallography.

Fundamental forms of crystals.—A very superficial acquaintance with mineralogy and inorganic chemistry, will convince you, that there is a prodigious variety of shapes presented by crystallized substances. A late writer on mineralogy tells us, that the crystalline forms of one substance (carbonate of lime) exceed 1400! The accumulated labours of late crystallographers have shown, that the thousands of known crystalline forms may be reduced to six, which are called *fundamental forms*, or *types*; and that all the others are *modifications* or *derivations* of these. Hence,

therefore, six *groups* or distinct *systems* are now usually admitted: they are as follows:—

GROUP 1st. This is denominated the REGULAR, TESSULAR, TETRAHEDRIC, or CUBIC system; and includes all those crystals whose fundamental form is the *hexahedron* or *cube*. The *primary* forms belonging to this group are the cube, the tetrahedron, the regular octahedron, and the rhombic dodecahedron. To this system belong *common salt, alum, muriate of ammonia*, and *arsenious acid*.

GROUP 2d is called the SQUARE RIGHT PRISMATIC SYSTEM; the fundamental form being a *right prism, with a square base*. The *primary* forms belonging to this group are the octahedron, with a square base, and the right square prism. To this system belongs *calomel*.

GROUP 3d constitutes the RECTANGULAR OR RHOMBIC RIGHT PRISMATIC SYSTEM; the fundamental form being a *right prism, with a rectangular or rhombic base*. The *primary* forms belonging to this group are the rectangular octahedron, the rhombic octahedron, the right rectangular prism, and the right rhombic prism. To this system a considerable number of pharmacological agents belong; for example, *citric acid; sulphate, nitrate*, and *bitartrate of potash; sulphate of magnesia; tartarized soda: tartarized antimony; nitrate of silver; corrosive sublimate; sulphate of zinc*; and *sulphur* (both the native and that crystallized from its solution in bisulphuret of carbon).

GROUP 4th. This is termed the RECTANGULAR OR RHOMBIC OBLIQUE PRISMATIC SYSTEM; the fundamental form being *an oblique prism, with a rectangular* or *rhombic base*. The *primary* forms belonging to this group are the rectangular oblique prism, and the oblique rhombic prism. It contains *tartaric acid; phosphate, sulphate, and subcarbonate of soda; sulphate of iron; sulphur* (when crystallized by slow cooling); and *chlorate of potash*.

GROUP 5th is denominated the DOUBLY OBLIQUE PRISMATIC SYSTEM; the fundamental form being *an oblique prism, with a rhomboidal base*. In this group we find *sulphate of copper*.

GROUP 6th. This is called the RHOMBOHEDRIC SYSTEM; the fundamental form being a *rhombohedron*. The *primary* forms belonging to this group are the rhombohedron, the six sided or hexagonal prism, and the double six sided pyramid (sometimes called the bipyramidal dodecahedron). To this system belongs *carbonate of lime*.

Having premised these remarks on the pharmaceutical crystals, I proceed now to examine the individual substances of the inorganic materia medica.

Class I. UNDECOMPOSED NON-METALLIC PHARMACOLOGICAL AGENTS. To this class belong *oxygen, chlorine, iodine, carbon, sulphur*, and *phosphorus*.

I. OXYGEN GAS.

History, synonymes, and etymology.—This gas was discovered on the 1st of August, 1774, by Dr. Priestley, who denominated it *dephlogisticated air*. In the following year, Scheele also discovered it, without knowing what Priestley had done, and he called it *empyreal air*. Condorcet termed it *vital air*, and Lavoisier gave it the name it now usually bears (oxygen), deriving the word from ὀξυς, *acid*, and γενναω, *to produce*.

Native state.—It makes up $\frac{3}{4}$ of the known portion of the terraqueous globe. Thus it constitutes $\frac{8}{9}$ of water. Now three-fourths of the surface of the earth are covered by water. I think we may safely say $\frac{1}{3}$ of the known solid crust of our globe is oxygen. You will also recollect that it constitutes a considerable proportion of the atmosphere—namely, $\frac{1}{5}$ of the air properly so called, $\frac{8}{9}$ of the aqueous vapour, and $\frac{16}{22}$ of the carbonic acid. It is an essential constituent of the organic kingdom.

Production.—The methods of procuring oxygen are numerous. I shall only notice three.

(*a*) *By heating chlorate of potash in a green glass retort.*—By this process we obtain pure oxygen gas. Every atom of chlorate of potash yields six atoms of oxygen and one atom of chloride potassium.

Reagent.	Result.
$\dot{K}\ \overset{.....}{Chl}.$	6 O
	K Chl.

(*b*) *By heating peroxide of manganese in an iron bottle.*—This is by far the cheapest method, and, for pharmacological purposes, the product is sufficiently pure. If any carbonic acid be suspected, we may purify the gas by passing it through lime-water. Two atoms of the peroxide are resolved, by heat, into one atom of deutoxide and one atom of oxygen.

Reagent.	Result.
2 $\ddot{M}ang.$	1 O
	$\underline{\dddot{M}}$

(*c*) *By heating peroxide of manganese with about its own weight of strong sulphuric acid in a green glass retort.*—This process is only to be followed when you have not the apparatus for procuring it by the second method. The results are proto-sulphate of manganese and oxygen gas.

Reagents.	Results.
1 $\ddot{M}ang.$	1 O
1 $\dddot{S}$	1 $\dot{M} + \dddot{S}$

Properties.—It is elastic, colourless, odour-

less, tasteless, incombustible, but a supporter of combustion. Its specific gravity is 1·1026; its atomic weight is 8, its combining volume 0·5. It is sparingly soluble in water.

Characteristics.—If a taper or match be plunged into this gas after the flame has been blown out, but while the wick or charcoal remains ignited, the flame is reproduced. The only gas likely to be confounded with oxygen in this respect, is the protoxide of nitrogen, from which oxygen is distinguished by exploding with hydrogen. A mixture of oxygen and hydrogen yields, by explosion, water only, whereas the protoxide of nitrogen with hydrogen, yields water and nitrogen.

Physiological effects. — Let us examine these under the two following heads :—

(*a*) *Effects of the inhalation of oxygen gas.*—We know that oxygen, as a constituent of atmospheric air, is essential to the existence of all living beings, and hence its common appellation—*vital air.* At one period the nitrogen of the atmosphere was supposed to be a negative agent—that is, it was thought to be a mere diluent to the oxygen. This notion doubtless led to the opinion of Priestley, that as a candle burns out much faster in oxygen than in common air, so we might, as it may be said, live too fast, and the animal powers be too soon exhausted in this pure kind of air.

Without occupying your attention unnecessarily, with preconceived notions respecting the effect of this gas, I may state that later experimenters have proved, no very obvious effects result from a few inhalations; that an animal will live longer in a given volume of this gas than in the same volume of atmospheric air, but that the continued use of it causes death. It quickens the respiration and excites the vascular system, then causes feebleness and insensibility; to which symptoms succeed loss of voluntary motion, and, ultimately, death.

The following remarks made by Nysten deserve notice in connexion with the foregoing :—"Respired in the pure state, this gas does not excite any catarrhal affection; injected into the pleura it is very quickly absorbed without causing inflammation, as I have many times assured myself; lastly, dissolved in the venous system, as happens when we have cautiously injected it, no sensible effect is produced on any part of the animal economy."

(*b*) *Effects of oxygenated water.*—By strong pressure water may be made to dissolve a certain quantity of oxygen, and the liquid thus produced has been denominated *oxygenated water.* It must not be confounded with the peroxide of hydrogen. This oxygenated water is said to act as a slight excitant, promoting the appetite and increasing the secretions.

Uses.—In asphyxia, arising from either deficiency of atmospheric air, or from breathing noxious vapours, the inhalation of oxygen has been said to be useful. So also during an attack of spasmodic asthma, when the system seems to be suffering from a want of atmospheric air, oxygen might, perhaps, be inhaled with advantage; but it can only be useful as a palliative. Chaussier has recommended its use in children apparently still-born. It has also been employed in diseases supposed to arise from, or be connected with, a deficiency of oxygen, as malignant cholera, chlorosis, &c. It is, however, rarely employed.

2. Chlorine Gas.

History and synonymes.—This gas was discovered by Scheele in 1774, who termed it *dephlogisticated muriatic acid.* Berthollet, in 1785, named it *oxygenated muriatic acid*, from an erroneous notion of its composition. Sir H. Davy, who determined its elementary nature, called it *chlorine* (from χλωρος, green) on account of its colour.

Native state.—It is found in both kingdoms of nature. Thus it exists native in combination with a number of metals, as sodium, lead, silver, &c. Free hydrochloric acid is found in the neighbourhood of volcanoes, in all probability being evolved from some chloride or muriatic salt; and, according to Dr. Prout, it exists in the free state in the stomach of animals during the process of digestion.

Preparation.—The best method of procuring chlorine is to introduce a mixture of one part common salt and one part powdered oxide of manganese into a retort, and then add two parts strong sulphuric acid (diluted with two parts water). By the application of a gentle heat the gas is copiously evolved. In the absence of peroxide of manganese we might obtain chlorine by adding muriatic acid to the chloride of lime, which is now found in most chemists' shops.

The *theory* of the process is this :—One atom of sulphuric acid acting on an atom of peroxide of manganese generates the proto-sulphate of manganese, while one atom of oxygen is set free; this immediately combines with an atom of sodium of the common salt, to form soda, with which some sulphuric acid unites, producing sulphate of soda : the chlorine of the common salt is set free.

Reagents.	Results.
$N + Chl.$	$Chl.$
$\ddot{M}$	$\dot{N} + \dddot{S}$
$2\ \dddot{S}$	$\dot{M} + \dddot{S}$

Properties of the gas.—It is elastic, and has a yellowish green colour, and a pungent suffocating odour. Its specific gravity

is 2·47. It is not combustible, but is a powerful supporter of combustion. Some substances, as phosphorus and antimony, take fire when introduced into it. It destroys vegetable colours when water is present; its efficacy depending on its decomposing the water and uniting with the hydrogen to form hydrochloric acid, while the colouring matter combines with the disengaged oxygen.

Oxide of colouring matter (i. e. colourless matter).

Colouring matter	Oxygen	*Water.*
Chlorine	Hydrogen	

Hydrochloric Acid.

The atomic weight of chlorine is 36: its atomic volume 1.

Characteristics.—The colour, odour, and bleaching property of chlorine, readily distinguish it. Dissolved in water, small quantities of this gas are distinguished by the power the solution has of dissolving leaf gold. In common with free muriatic acid and the chlorides, it precipitates the nitrate of silver white; the chloride of silver thus formed being soluble in ammonia, but insoluble in nitric acid.

Physiological effects.—Chlorine gas is a *local* irritant. Mr. Wallace tells us that diluted with air, or aqueous vapour, of 116° Far., and applied to the skin, it produces peculiar sensations, similar to those caused by the bite or sting of insects: this effect is accompanied with copious perspiration, and a determination of blood to the skin, sometimes attended with an eruption of minute papulæ, or even vesicles. Applied to the skin in a pure form, its action is similar, but more energetic.

If an attempt be made to inspire undiluted chlorine gas, immediate death may be the consequence, from spasm of the glottis. If the gas be mixed with air, it enters into the bronchial ramifications, produces a sensation of tightness and suffocation, and violent cough. Twice I have suffered most severely from the accidental inhalation of it; and each time I have been impressed with the belief, founded on my own feelings, that it caused a diminution of the calibre of the air-tubes, arising from a spasmodic condition of the muscular fibres of the bronchial tubes. The attack usually goes off in increased secretion from the mucous membrane. When diluted with a large quantity of air, chlorine may be inhaled without exciting cough: it occasions a sensation of warmth in the respiratory passages, and promotes expectoration.

The irritating effects of chlorine are less powerful on those accustomed to inhale it; as I have repeatedly seen in patients who were using the gas, and which is also shown by a statement made by Dr. Christison. "I have been told (says he) by a chemical manufacturer at Belfast, that his workmen can work with impunity in an atmosphere of chlorine, where he himself could not remain above a few minutes."

The constitutional or *remote* effect caused by inhalations of chlorine, is increased frequency of the pulse and of respiration. But this effect may be in part owing to the increased muscular efforts of the patient. Mr. Wallace states, that the application of chlorine to the skin also occasions soreness of the mouth, fauces, and œsophagus; increased vascularity, and even minute ulcerations of these parts, and an alteration in the quantity and quality of the salivary and biliary secretions. He thinks also that it has a tranquillizing, and at the same time exciting power, with respect to the nervous system.

When applied to the skin, or bronchial membrane, does chlorine gas become absorbed? If Mr. Wallace's observation be correct, we must infer that it does, and that it is thrown out of the system by the kidneys; for he says the urine acquires bleaching properties. Nysten has tried the effects of injecting the gas into the blood; and found small quantities produced little effect, but larger ones occasioned difficult respiration, and in three minutes death: the blood was fluid, and, even in the left auricle and ventricle, had a venous character.

Uses.—(*a.*) *As a fumigating agent, disinfectant, and antiseptic*, chlorine, I believe, stands unrivalled. Hallé, in 1785, appears to have been the first person who employed it as a disinfectant; but we are greatly indebted to Guyton-Morveau for the zeal and energy he manifested in his attempts to introduce it into use. For destroying miasmata, noxious effluvia, and putrid odours, it is the most powerful agent known; and is, therefore, well adapted for disinfecting prisons, ships, hospitals, dissecting rooms, and all other places, the air of which requires purification. The best method of fumigating a large building is that adopted by Dr. Faraday, at the General Penitentiary at Milbank. One part of common salt was intimately mixed with one part of the black oxide of manganese; then placed in a shallow earthen pan, and two parts of oil of vitriol, previously diluted with two parts by measure of water poured over it, and the whole stirred with a stick. Chlorine continued to be liberated from this mixture for four days. To show you on what an immense scale these operations were conducted, I may add, that he consumed 700 lbs. of common salt, 700 lbs. of oxide of manganese, and 1400 lbs. of sulphuric acid. The disinfecting power of chlorine

is supposed to depend on its affinity for hydrogen, by which it effects the decomposition of water or aqueous vapour, the hydrogen of which it unites with, while the oxygen oxidizes the organic matter; or it may act merely by abstracting hydrogen from the putrid miasmata.

(*b.*) *As an antidote in poisoning by hydrocyanic acid, sulphuretted hydrogen, or hydrosulphate of ammonia*, chlorine gas is a very valuable agent. In a very recent lecture, I sufficiently examined the efficacy of this antidote in poisoning by the hydrocyanic acid. I believe, however, that the chloride of lime will be found a more convenient, safe, and opportune agent: its activity depends on the chlorine present. The beneficial influence of chlorine in the treatment of animals asphyxiated by sulphuretted hydrogen, doubtless arises, at least in part, from its chemical properties; for when the two gases are mixed, we obtain chloride of sulphur and hydrochloric acid. The best method of applying the remedy is to diffuse a little chlorine in the air, and then to produce artificial respiration.

(*c.*) *Inhaled in chronic pulmonary diseases* it is sometimes a useful remedy. I have carefully watched its effects in phthisis and other chronic diseases of the lungs; and the result of my observation is, that chlorine is rarely serviceable. Frequently, after the first and second inhalations, the patients fancy their breathing much relieved, while the expectoration is promoted, but the amendment is seldom permanent. I need hardly say it has no pretensions to the cure of phthisis, but it may be useful as a palliative (sometimes diminishing the sweating); and I can readily believe that occasionally in chronic bronchitis it may be of essential service, though, I confess, I have never found it so.

The mode of administering the gas I have already detailed in a former lecture *. You may put either the aqueous solution of chlorine or a small portion of the chloride of lime, into the inhaling bottle: if the latter be not sufficiently strong, a few drops of muriatic acid are to be added.

(*d.*) *In diseases of the liver*, not attended with active inflammation, Mr. Wallace has successfully employed baths of gaseous chlorine, either in the pure state or diluted with air or aqueous vapour. The benefit of chlorine in these cases has been confirmed by others. The temperature of the bath, and the time the patient ought to remain in it, will vary in different instances; but Mr. Wallace thinks, that, in the greater number, 115° Fah. will be found to answer best, and the proper time about half an hour. The benefit obtained is in part referable to the heat employed, in part to the irritant effect of the chlorine on the skin, and (according to Mr. Wallace) in part to the specific influence of chlorine on the liver. Ziese, an apothecary at Altona, has also employed chlorine baths in these cases with advantage.

* See Lecture V. p. 132 of the present vol.

Antidotes.—The inhalation of ammoniacal gas, of the vapour of warm water, of spirit of wine, or of æther, has been recommended, to relieve the effects of inhaling chlorine. I tried them all when suffering myself, but without the least apparent benefit. In a case related by Kastner, and which is reported in Wibmer's work, the inspiration of sulphuretted hydrogen gave uncommon relief. If you employ this agent, do it cautiously; recollect the proposed antidote is a powerful poison.

(*a.*) *Solution of Chlorine.*

Preparation. — Chlorine dissolves in water, forming the *liquor chlorinii*, or *liquid oxymuriatic acid*. At the ordinary temperature and pressure of the atmosphere, one volume of water can dissolve two volumes of the gas. The easiest way of procuring this solution is the following: —generate the gas (from the ingredients already described) in a common oil-flask; and by means of a curved glass tube (one end of which is adapted to the flask by a cork), pass the gas into water contained in a double-necked bottle.

Properties.—A saturated solution of chlorine has a greenish yellow colour, and a strong odour of the gas. It bleaches vegetable colours—as tincture of litmus, turmeric, &c. By exposure to light, the water is decomposed, the oxygen is evolved, while the hydrogen unites with the chlorine to form muriatic acid.

Characteristic tests.—Like muriatic acid, the muriates, and the chlorides, it causes a precipitate with nitrate of silver, which is soluble in ammonia, but is insoluble in hot nitric acid. It is distinguished from them by its bleaching properties, its dissolving leaf gold, and its removing the blue colour of iodide of starch and of sulphate of indigo.

Physiological effects.—In a concentrated form, the aqueous solution of chlorine acts as a corrosive poison. Somewhat diluted it ceases to be a caustic, but is a powerful local irritant. Administered in proper doses (a few drops), and properly diluted, it is given internally, as a tonic and stimulant. The continued use of it is said to have caused salivation.

Uses.—Solution of chlorine has been employed therapeutically both externally and internally.

(*a*) *Externally*,—it has been used in the concentrated form as a caustic, applied to wounds caused by rabid animals; diluted, it has been employed as a wash in skin diseases, namely, in the itch and porrigo, and also as an application to cancerous and other ulcers attended with a fœtid discharge. In the latter cases I have repeatedly employed it with advantage, though I give the preference to a solution of the chloride of soda.

(*b*) *Internally*,—it has been administered in those diseases denominated putrid; for example, in the worst forms of typhus and scarlet fever. It has also been employed in venereal maladies. The dose will vary with the strength of the solution: if the latter be concentrated, from 20 to 30 drops in about an ounce of some diluent will be the proper dose.

Antidotes.—In cases of poisoning by a solution of chlorine, we are advised to employ those remedies used in poisoning by the acids, namely, magnesia, chalk, &c. A mixture of albumen and water, however, has been recommended by Devergie. For this purpose mix up some white of eggs with water. In the absence of these, use milk, (the caseum of which will be nearly as useful). The compound of chlorine and albumen which is formed, has very little action on the animal economy, and it may be readily evacuated from the stomach. The gastro enteritic symptoms are to be combated in the usual way.

(*b*.) *Chloride of Lime*.

History.—In the year 1798, a patent was granted to Mr. Tennant, a manufacturing chemist of Glasgow, for the manufacture of the substance now usually denominated *chloride of lime*, but which has been known by several other denominations, such as *bleaching powder*; *oxymuriate of lime*; *chloruret of the oxide of calcium*; and *chlorite of lime*. Do not mistake this substance for the chloride of calcium, a compound altogether different in its properties; nor for the chlorate of lime.

Preparation.—This substance is prepared on a most extensive scale for the use of bleachers; and a full account of its manufacture has been published by Dr. Ure, in the 13th vol. of the *Quarterly Journal of Science*. The principle of the process is simple, being that of merely bringing the gas in contact with recently slacked lime. On the large scale, the gas is generated in large, nearly spherical, leaden vessels, heated by steam; the gas produced is then washed by passing through water, and is carried by a leaden pipe into the combination room, where the slacked lime is placed in shelves or trays, piled one over another to the height of five or six feet, cross bars below each, keeping them about an inch asunder, that the gas may have free room to circulate.

Properties.—Chloride of lime, as met with in commerce, is a white pulverulent substance, having a feeble odour of chlorine, and possessing bleaching properties. Chemists are not agreed as to its nature. Thomson regards it as an atomic combination of chlorine and lime: Ure says it resembles "rather a mixture (or at most a saline solution) than a true atomic compound." Berzelius and Dumas, on the other hand, consider it to be a mixture of *chlorite of lime* and *chloride of calcium*,—its essential properties depending on the chlorite. They suppose that when the chlorine comes in contact with the lime, part of the latter is decomposed into its elements oxygen and calcium; the first forming, with chlorine, *chlorous acid*, which, with some undecomposed lime, forms *chlorite of lime*, while some free chlorine combining with the calcium, furnishes *chloride of calcium*.

Reagents.	Results.
4 Chl.	3 ($\dot{\text{Ca}}$. $\dddot{\text{Chl}}$).
4 $\dot{\text{Ca}}$.	Ca. Chl.

I have mentioned this opinion of Berzelius and Dumas, because from the high characters of these philosophers every theory of theirs deserves attention; but I confess it appears to me that we have not a sufficient number of facts to induce us to adopt their opinion, while several strong objections may be urged against it.

Characteristic tests.—The chloride of lime is recognized by the following characters: On the addition of sulphuric or muriatic acid, it readily gives out chlorine; its solution bleaches; it precipitates a solution of nitrate of silver white (the precipitate being soluble in ammonia, but insoluble in nitric acid); and a white precipitate is produced on the addition of oxalic acid or oxalate of ammonia. The last test shews the nature of the base, the others recognize the chlorine.

Physiological effects.—The effects of the chloride of lime on the system, have hardly as yet been properly determined. Locally, it evidently acts as an irritant; indeed, the lime present, and which the chlorine very imperfectly neutralizes, would render it so, and doubtless in its concentrated form it is to be regarded as a caustic. What the remote or constitutional effects of the chloride of lime may be, have not yet been ascertained experimentally. Cima regards it as a stimulant to the lymphatic glands, but without any good evidence.

Uses.—I shall speak of the uses conjointly with those of chloride of soda.

(c.) *Chloride of Soda.*

History.—This substance is sometimes termed *chloruret of the oxide of sodium, oxymuriate or chlorite of soda:* it constitutes the *liqueur de Labarraque.* In some works it is by mistake called *chlorate of soda,* a preparation never used in medicine. You must not confound chloride of soda with common salt (chloride of sodium).

Preparation.—It is prepared by passing chlorine gas into a solution of the subcarbonate of soda. The following quantities will produce a solution about the strength of that recommended by Labarraque:—Dissolve one ounce of subcarbonate of soda in four fluid ounces of distilled water, and into this solution pass chlorine gas generated from 2 drachms of peroxide manganese, 2 drachms of common salt, and 4 drachms of sulphuric acid, mixed with 4 drachms of water.

Payen has proposed to prepare it thus: Dissolve 2 parts of subcarbonate of soda in 18 parts of water, and add 1 part of the chloride of lime: filter. If only $1\frac{38}{100}$ of the subcarbonate be employed, the chloride will be neutral. If the subcarbonate of potash be employed in place of the soda, we should obtain a solution of the chloride of potash, formerly called *Eau de Javelle.*

Properties.—Labarraque's solution contains carbonate, bi-carbonate, and chloride of soda; or, to adopt the theory of Berzelius and Dumas, it is a mixture of carbonate, bi-carbonate, and chloride of soda, with chloride of sodium. It bleaches like the chloride of lime.

Characteristic tests.—These are similar to those mentioned for the chloride of lime, except that neither oxalic acid nor oxalate of ammonia causes a precipitate, showing that no lime is present: the chloride of platinum occasions no yellow precipitate, proving it is not the chloride of potash which is present. The solution, evaporated to dryness, leaves a residuum which renders the outer cone of the flame of a candle, or the flame of a spirit-lamp, yellow.

Physiological effects.—A strong solution of the chloride of soda acts as a corrosive poison, diluted as a local irritant merely. We are at present very imperfectly acquainted with its remote action.

Uses of the chlorides of lime and soda.—I propose to examine the uses of the chlorides of lime and soda under one head, and thereby to save much repetition, since they act in a very analogous manner, and are employed in the same cases. As the chloride of lime is manufactured on a very extensive scale for the use of bleachers, it can, of course, be obtained at a cheaper rate than the chloride of soda, and on this account, therefore, will probably always be more extensively employed in medicine, besides which, it is much more frequently met with in the shops, and hence can be obtained with greater facility. If, however, I were confined to the use of one chloride only, I should choose the chloride of soda, having frequently found this serviceable when the chloride of lime was not. Labarraque also gives the preference to the soda preparation, on the ground that by the process of disinfection these chlorides lose oxygen, the chloride of lime becoming chloride of calcium, while the chloride of soda is converted into the chloride of sodium or common salt. Now these two resulting chlorides possess different properties: chloride of calcium is a very deliquescent salt, while chloride of sodium is designated a "very dry salt." By attracting water, the chloride of calcium furnishes one of the conditions fit for re-producing the putrefactive process, whereas chloride of sodium "acts as a preservative, by coagulating the principle which commences putrefaction." These reasons (not very valid ones, I confess) led Labarraque to the conclusion, that while chloride of lime will serve for simple disinfection, chloride of soda is preferable when we wish at the same time to prevent the renewal of putrefaction. The chemical influence of these chlorides, or disinfectants, depends on the chlorine, which is separated from the base, by the union of the latter with the carbonic acid of the air.

1. *As disinfectants, antiseptics, &c.*—I have already stated my opinion that chlorine is unrivalled for its disinfecting and antiseptic properties; but you are not, therefore, to imagine, that to gain these effects we must necessarily employ it in its gaseous form. If you are called on to disinfect large uninhabited buildings, you could not do better than employ chlorine fumigation, as already described. But this process would not be admissible in inhabited places, on account of the irritating properties of the gas. Now it is in these cases that the chlorides are found so superior in practice to the chlorine fumigations. They evolve chlorine gas, it is true, but in such small quantities, as not to exercise any noxious effects; while they possess the same kind of disinfecting and antiseptic properties. Thus dissecting-rooms might be readily disinfected by throwing about a solution of these chlorides, while the anatomist was pursuing his studies.

These chlorides also possess another advantage: they may be applied with the greatest facility to substances in a state of putrefaction, so as not only to disinfect, but to stop the putrefactive process. It is with this view that we apply them to gangrenous parts, or to ulcers attended

with a fœtid discharge, thus ameliorating the condition of the patient, and at the same time counteracting what would otherwise be a great annoyance to his friends and attendants.

I should give but a very imperfect idea of the value of the chloride solutions in these cases, did I lead you to imagine their efficacy was confined to an action on the dead parts, or on the discharges from wounds or ulcers; they are also of the highest benefit to the living parts. Frequently by their employment the further progress of gangrene is stopped, the separation of the dead from the living parts promoted, and the secretions altered both in quality and quantity. To enumerate particular instances is, I conceive, unnecessary; it will be sufficient to say, that in all cases of gangrene, in ulcers attended with sloughing, or with a fœtid sanious discharge, whether phagedenic, cancerous, syphilitic, or scrofulous; in compound fractures also, which are frequently attended with most offensive discharges, you will find these chlorides of essential service, not only by their disinfecting and antiseptic qualities on non-vital substances, but also by their beneficial action on the living parts. On many occasions the chlorides are invaluable agents in the sick chamber, either by destroying unpleasant odours, or contagious or infectious matters. I have frequently recommended, with the greatest advantage to the attendants, a handkerchief dipped in a weak solution of the chloride to be suspended in the chamber of the patients suffering with fever. To counteract the unpleasant smell of the dressings or bandages, or of the secretions from patients, these chlorides will be found most useful.

2. *Chloride gargles.*—On many occasions gargles containing the chloride of soda or of lime prove of service: for example, in ptyalism and ulceration of the mouth, whether originating from the employment of mercury, or arising spontaneously; in ulceration of the throat, particularly that kind observed in malignant scarlatina, I have obtained beneficial results from the employment of chloride gargles.

3. *In poisoning by sulphuretted hydrogen gas, by the hydrosulphuret of ammonia, by the sulphurets of potassium and sodium, and by hydrocyanic acid* (some have added carbonic acid), the chlorides are of signal utility: in fact they may be regarded as genuine antidotes, since they decompose those poisons, and render them comparatively inert. When the patient is in a condition to swallow, I would recommend that a solution of the chloride should always be administered, in addition to the inhalation of the vapour. The latter is to be effected by dipping a handkerchief in a solution of the chloride, and applying it to the nose. It was by breathing air impregnated with the vapour arising from the chloride of lime, that Mr. Roberts (the inventor of the miner's improved safety-lamp), was enabled to enter, and traverse with safety, the sewer of the Bastile, which had not been cleansed for thirty-seven years, and which was impregnated with sulphuretted hydrogen. You will find an interesting account of his experiments in the late Mr. Alcock's "Essay" on the Chlorurets. If you were required to enter any place suspected to contain sulphuretted hydrogen, the safest mode of proceeding would be to place a handkerchief moistened by a solution of chloride of lime over the mouth and nostrils, so that all the air inspired would by this means be purified.

4. *In burns and scalds.*—Lisfranc has employed with great benefit lotions of the chloride of lime, sometimes immediately after the accident, sometimes after the application of emollient cataplasms. His method of using it is this: lint moistened with a solution of chloride of lime is applied to the part, and over this a waxed cloth. In one case, where almost the whole of the lower limbs, the arms, and face, had been burnt, the use of the chloride recovered the patient from the stupor into which he had fallen, at the end of four days; and a perfect recovery was effected two months after the accident.

5. *Injections* of the chlorides have been employed in diseases of the uterus, in gonorrhœa, in fistulous ulcers, &c. with advantage. In several very obstinate gleets I have tried a solution of chloride of lime, but without benefit. The chloride of soda is, I think, more useful.

6. In chronic *skin diseases*, where stimulating washes are usually applied, the chlorides have been beneficially employed. Thus in porrigo, impetigo, scabies, prurigo, and other cutaneous affections, lotions containing the chloride of soda have been found very beneficial. In a very obstinate case of prurigo pudendi muliebris, related by Dr. Darling, the chloride of soda afforded almost instantaneous relief.

In the year 1810, Cluzel observed that some Spanish prisoners were cured of the itch by dipping their hands into a solution of chlorine, for the purpose of preserving them against contagious fever. Derheims has used with the most perfect success, in the same disease, a lotion composed of three ounces of the chloride of lime to a pint of water. This is a much more pleasant and agreeable method of curing the itch than employing sulphur frictions.

7. *Ophthalmia* has been benefited by the chloride of lime solution. In the Medical and Physical Journal for November, 1827,

Dr. Varlez, surgeon to the Military Hospital at Brussels, states that in 400 cases this remedy never disappointed him; and Mr. Guthrie also reports favourably of it in three cases. MM. Colson, Delatte, and Raynaud, also speak in high terms of it. The strength of the solution employed by Dr. Varlez varied from one scruple of the chloride to three or four drachms, dissolved in an ounce of water. This was dropped into the eye, or injected by a syringe, or applied by means of a camel's hair pencil. Other means, however, must be conjoined, namely, bleeding, purging, cold, and, in chronic cases, blisters. I have seen a weak solution of great benefit in several cases of the purulent ophthalmia of infants.

8. *Internally* the chlorides (particularly the chloride of soda) have been employed in infectious fevers, venereal diseases, dyspepsia, &c.

Antidotes.—In the event of poisoning by chloride of lime or soda, you must carefully avoid administering acids, as they would cause the evolution of chlorine gas, which would not only irritate and inflame the stomach and œsophagus, but being inhaled, might perchance cause asphyxia or bronchial inflammation. The best plan, therefore, would be to administer albuminous or caseous liquids (as eggs beat up with water, or milk), or flour and water, or oil, or mucilaginous drinks, and to excite vomiting.

OBSERVATIONS

ON

URINARY DEPOSITS.

To the Editor of the Medical Gazette.

Sir,

Should the following observations on urinary deposits, which formed the subject matter of a thesis lately read before the Physical Society of Guy's Hospital, be deemed of sufficient interest, you will oblige by giving them a place in the columns of your valuable journal.

Your obedient servant,

R. H. Brett, M.R.C.S.

1, Upper Sussex-place, Old Kent Road,
Feb. 4th, 1836.

Comparison of Vital Chemistry with Inorganic.

The great advantages which have accrued to science from the investigation of chemical pathology must be manifest even to those whose attention has not been particularly directed to this branch of inquiry, the difficulties of which have certainly not diminished in proportion as its advocates have passed from the consideration of general principles to the careful examination of minute details.

The two great kingdoms of nature, that which comprehends inert and inanimate matter, and that which claims as its own the complex forms of living structures, are of a nature so widely different, that we can hardly be surprised that that mode of research which has been so pre-eminently successful in bringing before our view the elementary constituents of the one, should, in many instances at least, be found totally inefficient, when applied to the investigation of the other. Those laws which preside over the external conformation or molecular arrangement of inorganic matter, have, as far as our experience has hitherto enabled us to judge, remained immutable, so that those elements which have at one time under certain circumstances given rise by their association with other elementary principles to a definite form of matter, shall at another time under the same train of circumstances give birth to an analogous form, thus giving us the power of predicating certain results. But a similar mode of reasoning will not apply to that species of matter which, disdaining to be trammelled by laws purely physical, arrogates to itself a presiding agent for the regulation of its varied changes, of a nature so subtile as to elude our keenest scrutiny, and baffle all our ablest arts in the attempt to gain a mere glimpse of its true essence. What, indeed, can be more different than the chemistry of life and that of inert matter: the one carried on in all its inscrutable and mysterious process, without the aid of crucible or furnace, in the laboratory of a living system—wonderful in its complexity, though beautiful in its design and construction, with life for the directing alchymist; the other perfected by mere human ingenuity, exercised over the mute and senseless materials of the inorganic world! If, then, our imperfect knowledge altogether forbids us from following vital chemistry in the manifold details of her intricate processes, it is at least given us to examine the products which accrue from such processes; and although our labours in this field of inquiry must be crowned with much less satisfactory results than when engaged in sifting the elements of inorganic matter, still, considering the almost infant state of

this department of chemical knowledge, much that lays just claim to ability, and much that may be applied practically, has flowed from its steady cultivation. Our knowledge of the constituent parts of the various secretions and excretions is of a very different stamp from that which our predecessors enjoyed, and imperfect as it still must be allowed to be, has nevertheless led to a much more scientific and much more efficient mode of treating disease. Correct information relative to the proportions in which certain proximate and even ultimate principles enter into the constitution of that pabulum of our existence—the blood, when in a healthy condition, is absolutely necessary, in order to allow of our detecting any deviation from that state, which, none but the most determined solidists will deny, may be the fruitful cause of disease. What that aberration from the normal standard precisely may be in the varied forms which disease puts on, must, I fear, be left for a more enlightened chemical era than the present to determine; but doubtless, considering the rapid advances which science now makes, the time may be confidently looked forward to when such a knowledge shall enable its possessors to apply their remedial agents more directly to the vital fluid itself, be its diseased condition the result of a deficiency or redundancy of its healthy constituents, or be it caused by such a perverted or morbid state of the latter as to give rise to new products. And when we remember that the ultimate elements of all organic principles strictly called animal, however different in their physical and chemical nature such principles may be, actually exist in the blood, it requires no inordinate or unreasonable stretch of the imagination to allow that vital agency may so alter the atomic arrangement of such elemental bodies as to give rise to proximate principles of a nature altogether different from those which we meet with in healthy blood; by a mode of synthesis, indeed, totally removed from our powers of comprehension.

The condition of the urinary secretion has of late years been very attentively studied, and its departure from the healthy standard very carefully marked; and there is, perhaps, no secretion so prone to undergo changes from the influence of morbific causes. There is scarcely a disease in the whole catalogue of ailments to which human nature is subject, where this fluid will not be found more or less altered from its healthy condition. In the phlegmasiæ its aberration from that state is constantly, or almost constantly, manifested: in those diseases, too, which, if inflammatory, are of a decidedly specific character, such as rheumatism and gout, both acute and chronic, this secretion has long been noticed as undergoing some peculiar alteration. In the varied forms of dropsy this fact is not less obvious. In those morbid states of the system in which the lumbar portion of the spinal nerves appears principally affected, a corresponding derangement of the urinary secretion is commonly met with. In those proteus-like forms of disease, hysteria and dyspepsia, changes of a no less marked character in the urine are constantly being brought before our notice. In that hitherto opprobrium of the medical art, both in respect to its pathology and treatment, I mean diabetes, an extraordinary and very unusual change is observed to take place.

A knowledge of these several facts has justly led medical men to attribute no trifling importance to the study of the chemical pathology of the urine, and the happiest results have followed its careful investigation, both in throwing an additional light upon the pathology of the urinary organs in particular, and in rendering diagnosis more clear and perfect, and consequently fixing the treatment of disease upon a more scientific and more efficient basis.

To enter upon a subject which, although it has been much agitated by some of the ablest investigators, is still very far (owing to the nature of the subject) from even an approach to perfection, needs, I think, no apology, more especially as the remarks which are about to follow will not be directed so particularly to the urine itself, as to the deposits which that secretion under various circumstances gives rise to; nor will exclusive attention be paid to those deposits which are commonly classed under the term urinary.

Nature of the present Inquiry.

It is my intention in this paper to treat in the first place of those deposits, or sediments, the constituents of which may be found in healthy urine, though not precisely in the same state of combination as we find them in that secre-

tion, and which become manifest either from disordered action of the kidney or urinary bladder. Secondly, of these which result from certain ingesta being taken up by the absorbents, and transferred without undergoing decomposition into the urinary passages, the constituents of which are not to be found in healthy urine; and lastly, those deposits, also consisting of principles not to be found in healthy urine, and which accrue either from a deranged action of the kidney, of a nature different from that observed as giving rise to the first class, by which the blood is allowed to pass into the urinary canals without undergoing that change which the healthy action of secretion always produces, or from actual disorganization of the kidney, or a morbid secretion from the urinary canals or bladder. And whilst noticing these various deposits, I shall endeavour to point out what appears to be the best means of distinguishing them from each other, independently of their mere physical differences, without which knowledge a correct diagnosis can hardly be formed, or satisfactory plan of treatment pursued.

Deposits, Organic or Inorganic.

Those deposits which consist of the same constituents as are found in healthy urine, may be divided into those which are of a strictly organic nature, into those which are made up of an organic acid and earthy or alkaline base, and into those which consist of an inorganic acid and earthy or alkaline base. The organic deposits consist of mucus, lithic acid, and the colouring principle of the urine; which last, when precipitated, is always combined with some of the saline constituents of the urine, and never in a free state. Those which consist of an organic acid and earthy or alkaline base, are made up of lithate of ammonia, lithate of soda, lithate of lime, and some other salts, commonly in minute proportions, and not essential to the deposit. Those consisting of an inorganic acid, and earthy and alkaline base, are made up of phosphate of lime and phosphate of ammonia and magnesia.

Mucous Deposits.

The organic deposits must be now noticed; and first, mucus. This substance, which is a secretion from the mucous membrane of the bladder, is always deposited even from healthy urine, upon cooling, although in small quantity. It is probably from the presence of this substance that healthy fresh urine gives evidence of a certain degree of viscidity when agitated. It is most probable that the mucus is not in a state of solution in the urine, but only suspended through that fluid in a state of exceedingly fine division. When urine is first voided, the mucus cannot be perceived, in consequence of its power of refraction being about the same as that of the fluid through which it is diffused; when, however, the latter cools, the mucous particles cohere, become increased in density, and consequently in refrangibility. It must not be supposed that the mucus of the urinary bladder is precisely similar to that secretion as found on other mucous surfaces; they all, indeed, have one physical property in common—viz. that of viscidity, but, nevertheless, experiment has shown that the mucus obtained from the gall-bladder, that from the stomach and intestinal tube, and, lastly, that obtained from the urinary bladder (which is the species to be presently more fully noticed), all differ in some of their chemical habitudes. Thus the mucus obtained from the lining of the gall-bladder, is, according to Berzelius, totally insoluble in acids; whereas that obtained from the urinary bladder is soluble, to a certain extent, both in diluted acids as well as in alkaline solutions: nor is it to be deemed, I think, a matter for surprise that this should be the case, when we reflect upon the different conditions different structures supplied with mucous membrane are placed under. Thus the bronchial tubes, the stomach and intestinal canal, and, lastly, the urinary bladder, are very differently circumstanced; the first being constantly exposed to the action of the external atmosphere, the second to the influence of an endless variety of ingesta, and the third to a highly irritating and saline fluid. The following are the appearances which the small quantity of mucus which always comes down from healthy urine upon cooling assumes. After the urine has stood for some time in a tall glass vessel, the lower strata of the fluid will be found to have lost their transparency, and an exceedingly light nebulous-looking substance will be observed floating in it: if the whole be thrown upon a filter, with a view of examining the

nature of this cloudy deposit when separated from the supernatant fluid, so exceedingly light and inconsiderable in quantity is the mucus, that no appreciable residue will remain on the filter, unless a very considerable quantity of urine be employed. But although the mucous deposit from healthy urine is thus inconsiderable in quantity, it is very different in disease; then it is that the deposition for the most part takes place before the urine is evacuated from the bladder; consequently that fluid will be found turbid, and sometimes even ropy, at the moment of its emission. If urine of this character be allowed to stand for a few hours in a tall glass vessel, a very abundant opaque deposit will take place: this deposit is ropy and tenacious, and devoid of the yellowish green colour which is so characteristic of the purulent deposit to be noticed hereafter. When collected upon a filter and washed, it appears semi-gelatinous from the absorption of water, is somewhat less opaque, and sometimes, from its exceeding tenacity, may be drawn out into threads. When allowed to dry on the filter it shrinks considerably, and assumes the character of a yellowish varnish: if it be then moistened with water it regains its former pulpy appearance and viscid character, and will be found to be soluble in caustic alkali, and, to a certain extent, also in acetic acid. It is sometimes found associated with a very considerable quantity of phosphate of lime; at other times, however, the proportion of the earthy phosphatic salt is inconsiderable, and in some cases the urate of ammonia is found in combination with the mucous deposit. The best mode of distinguishing this vesicle mucus from pus will be noticed when the latter substance is treated of.

There is a peculiar substance which appears to me to be a species of mucus, found not unfrequently under the following circumstances, but which I do not find noticed any where. I have observed in several instances, more particularly where the urine has deposited that form of lithates which is either so pale as to approach closely in physical character to the phosphate of lime, or accompanied with only a very small proportion of the colouring matter of the urine, giving it a yellowish or very pale fawn colour, that although the urine thus rendered turbid by the deposit in question, clears entirely by the application of heat, even below the boiling point of water, still, if, after it has been rendered thus transparent, brisk ebullition be kept up for a short time, it becomes again turbid; not, indeed, to the same extent as at first, but nevertheless manifestly so, and this takes place without any diminution of that acidary reaction which the urine has been observed to possess in these cases, both before and after boiling. If a drop or two of concentrated nitric or muriatic acid be added to this turbid urine, it becomes in no degree clearer; such a deposit cannot, therefore, be phosphate of lime: that it is not albumen is shown, both by the effect of a temperature applied below the boiling point of water, which does not cause this deposit to take place, although it always coagulates albumen; in addition to which it is found, that if nitric acid be added to such urine as soon as it is voided, and whilst perfectly clear, no turbidity is produced.

Lastly, it cannot be considered identical with that form of mucus which Dr. Prout speaks of as being thrown down by heat from certain specimens of urine, and which, he considers, is probably derived from the prostate gland, for this last, according to Prout, is coagulated by acetic acid, which is not the case with the peculiar substance in question; for acetic acid added to such urine, recently voided, causes no alteration. Its properties were further examined by collecting it on a filter, and in doing this care must be taken to throw the urine on the filter whilst hot, otherwise the lithates will become deposited and mixed with the organic substance. When thus separated by filtration it assumes the appearance of a semitransparent, somewhat tenacious substance, behaving towards re-agents much in the same way as mucus obtained from healthy urine upon cooling. The fact of this substance being thrown down from urine by boiling might lead one to suspect the presence of albumen in the fluid, and I doubt not this mistake has occasionally been fallen into. If urine, yielding this organic deposit by boiling, be rendered transparent by warming, so as to take up the lithates diffused through it, and then treated with tincture of galls or corrosive sublimate in solution, a slight troubling is induced; this, however, is not caused by albumen, for mucus and the extractive matter of

the urine, which is soluble in alcohol of a certain specific gravity, cause a troubling when tincture of galls is added to their solutions, and it is only when tincture of galls causes a considerable precipitate in urine that we have very strong reasons to suspect the presence of albumen. The phosphates and lithates contained in the urine may also, under certain circumstances, precipitate corrosive sublimate, for the phosphate of the peroxide of mercury is insoluble in water, though soluble in an excess of phosphoric acid: neither can this substance be confounded with caseous matter, for this last is thrown down—viz., caseous matter, by acetic acid; whereas it has been already shown that the urine in question is not affected by that acid. It is not improbable that the peculiar substance Prout speaks of as derived from the prostate gland, is caseous matter.

Uric or Lithic Acid Deposits.

The next deposit of a strictly organic nature which comes under consideration is the lithic or uric acid. This principle is never deposited in a state of perfect purity, it being invariably combined with a larger or smaller proportion of the colouring matter of the urine, and the merest trace of earthy phosphate: it constitutes the crystalline sediment or gravel of Dr. Prout, and this chemist is of opinion that the acid does not exist in a free state in the urine, but in combination with ammonia. He also considers that urate of ammonia is not incompatible in the same solution with the acid phosphate of ammonia. This statement would lead us to the belief that phosphoric acid is capable of dissolving free lithic acid, for we can hardly conceive it possible that lithate of ammonia could exist as such in association with free phosphoric acid, considering the very superior acidifying properties of the latter acid compared with uric acid. This, however, is not precisely the case, for if we take a solution of lithate of ammonia in water, and treat such a solution, divided into two equal portions, with acetic acid and phosphoric acid, the uric acid is thrown down in both cases: it is true, that in the urine the quantity of free phosphoric acid is inconsiderable, and in a state of much dilution, which circumstance might perhaps prevent the precipitation of uric acid. Dr. Prout also argues against the probability of free uric acid existing in the urine, from the fact that the latter acid requires a much larger proportion of water for its solution than it meets with in the urinary secretion, the proportion in that fluid being estimated at 1 part in 1000: but this does not decide the question; for that illustrious chemist Berzelius, has shown that certain inorganic substances are rendered much more soluble in water by the mere addition of certain binary soluble compounds to that menstruum. Thus, he found that iodine, which, in a free state, requires as much as 700 parts of water for solution, is taken up in much larger proportion when the muriate of ammonia or soda is also present, although we are not acquainted with any actual definite compound consisting of these last salts and iodine. Reflecting upon these discrepancies of opinion, it becomes a matter of importance to determine, by direct experiment, whether free lithic acid is, or is not, capable of being dissolved in larger proportion in water, when that menstruum holds in solution the same, or some of the same, salts as are found in healthy urine. For this purpose the acid phosphate of ammonia, with phosphate of soda and muriate of ammonia, all of which are to be found in urine, were dissolved in water, and then a portion of uric acid, much more considerable in quantity than the water in which the above salts were dissolved could have taken up by itself, was added. After submitting this mixture even to a boiling temperature, no appreciable quantity of the uric acid was dissolved. It might, at first sight, appear that this experiment was conclusive of the question, but, upon further consideration, it appeared to me that the following objection might be raised against it:—The lithic acid, in the experiment above detailed, was not recently precipitated or in an hydrous form, for it had been collected on a filter, after throwing it down from the urine by means of sulphuric acid, well washed, and dried at the ordinary atmospheric temperature: it could not, therefore, be fairly regarded as analogous to the same principle when just secreted by the kidneys: for although, in the present state of our knowledge, it is quite impossible to determine in what exact state the uric acid exists when first separated from the blood by the mysterious agency of its natural secreting organ, of this, I think, we may be certain, that it cannot be in

an anhydrous state, or, perhaps, even in a solid form. Admitting the truth of this position, it appeared necessary to alter the conditions of the experiment, and try the effect of the salts above-named upon the acid principle before it could have undergone those manifest, but not readily explicable, changes which matter, both of an organic as well as inorganic nature, undergoes by being brought to a dry state. For this purpose the following experiment was had recourse to:—A portion of urate of ammonia was dissolved in water, and an excess of muriatic acid, so as to precipitate free uric acid, added; the whole was then thrown upon a filter, and the acid washed with cold water until the fluid which came through no longer coloured litmus paper. The uric acid diffused through the last wash-water was divided into three equal portions: to the first of these a given measure of distilled water; to the second, an equal bulk of a solution of the acid phosphate of ammonia, phosphate of soda, and muriate of ammonia; and to the third, the same proportion of fresh healthy urine, were added: these several solutions were then heated for the same length of time: in neither case was a solution of the uric acid obtained. The insoluble residue was also found of nearly equal quantity in all three cases. Hence it may be inferred that uric acid is not rendered more soluble in water when that fluid contains in solution the acid phosphate of ammonia, phosphate of soda, and muriate of ammonia, neither does urine, with its various saline and organic principles, appear to possess the property of holding in solution any additional quantity of uric acid above that which is found as its ordinary complement, and which may possibly exist in a free state. How far certain of the extractive animal matters contained in the urine, with or without any association with its saline constituents, may favour the solubility of free uric acid in water, remains yet to be determined. Dr. Prout has characterized the free lithic acid deposit as crystalline, in which circumstance he considers it differs from the amorphous deposits of urate of ammonia, which do not assume a marked crystalline appearance. Berzelius states that the free uric acid is deposited in an argillaceous form, and acquires, when collected and dried, the appearance of thin plates; the more decided the crystalline form assumed by the precipitate, the less pure is the lithic acid, and the larger the proportion of bases united with it. He states also that a deposition of urate of ammonia from urine, upon cooling, is rare; and believes that the presence of mucus in the urine has a considerable share in causing the deposit of the latter salt. Thus, if two portions of urine be taken, and one carefully filtered whilst warm, so as to free it as much as possible from mucus, the deposit which afterwards takes place from such urine is uncombined lithic acid, in the form of plates, without any marked crystalline structure; whilst the deposit which ensues from the filtered portion of urine assumes a striking crystalline appearance, and contains a considerable quantity of ammonia. This statement of Berzelius respecting the different appearance of these deposits, does not appear to be borne out by facts of an every-day occurrence; by far the greater proportion of urinary deposits are of the non-crystalline kind, and are evidently combinations of uric acid and a base. The consideration of these will not be now entered upon, as they will have to be noticed in full when I come to them in the arrangement started out with, but shall confine my remarks to that deposit which strictly consists of uric acid unassociated with a base, and endeavour to point out in what manner it may be distinguished from all other deposits found in the urine, both as regards its physical properties and its behaviour towards different re-agents.

Tests of Uric Acid.

This peculiar substance, which occurs much less frequently in a free state as a precipitate than when combined with bases, appears to possess a greater affinity for the reddish-brown colouring matter of the urine than any other principle contained in that secretion; it is consequently deposited, for the most part, of a deep red or brown colour; sometimes, indeed, the colour is that of the darkest mahogany: this depth of tint, however, is not very commonly met with, and is, I believe, always co-existent with urine highly impregnated with colouring matter. This sediment is found to adhere with some tenacity to the sides of the containing vessel; and in some cases, when collected upon a filter, washed and dried, assumes an appearance so closely resembling red ferruginous sand, as per-

haps not to be distinguishable from it by mere inspection. The grains of which it is composed have little or no cohesion, possess a brilliant aspect, similar to powdered quartz or sand; are rough to the feel, and speedily sink in water: if boiled in repeated portions of water, they lose some of their colour, but not their brilliancy or specific gravity; they are not soluble to any extent in water, requiring as much as 10,000 times their weight of that fluid at 60° F., for solution. If a small portion of the lithic acid deposit be ignited, it blackens, and is dissipated, without leaving any appreciable residue; if, however, a larger portion be employed, a very striking odour is evolved during the application of heat, similar to that of prussic acid, and a small white ash remains, consisting generally of phosphate of lime. A solution of caustic potass or soda readily dissolves this deposit; and if it have been previously well washed, no ammoniacal odour is evolved. Any of the common acids, even the carbonic, throw it down again from its solution. The most characteristic test of all, however, is the action of nitric acid, diluted with two or three times its bulk of water: upon applying heat, the uric acid is speedily dissolved; and if the fluid be cautiously evaporated to dryness, a pink stain is produced, much heightened in colour by the addition of a little caustic ammonia.

Colouring Matter.

These means will be found amply sufficient to distinguish the lithic acid deposit from any other which may be met with in the urine; and its mode of detection has been somewhat fully entered upon, since in forming a diagnosis it is of great importance that the true nature of the deposit should be understood; for the fact that such a precipitate takes place from the urine, would seem to point out a much more serious derangement of the kidneys, as well as general health, than is indicated, in most cases at least, by the deposition of the non-crystalline lithic deposits. In those painful attacks called gravel, the lithic acid is for the most part the prevailing sediment; whereas the amorphous deposits may occur from simple derangement of the stomach, and in a variety of other morbid conditions, without there being any of those symptoms present which are ordinarily associated under the term gravel. A knowledge, too, that this species of sediment exists, might also induce us to administer alkalies more freely than might be deemed necessary, or even prudent, in those cases where, from the circumstance of the acid principle being combined with a base, it would, from its more ready solubility in the urine, be less likely to form those concretions which, being too large to pass with the urine, become shut up and augmented in the urinary bladder. In the administration of carbonated alkalies for this class of sediments, the effect produced on the urine should be watched, for a too free exhibition of the remedy might have a tendency to diminish the solubility of the lithic acid; for it is found by experiment that a portion of lithic acid which would be dissolved in a diluted solution of carbonate of soda or potass, is positively rendered in great measure insoluble by employing a more concentrated solution of the salt. Thus Wetzlac found that when he employed a solution of carbonate of potass in the proportion of one part of the salt to twelve parts of water, that it did not dissolve a certain portion of lithic acid which was added to it; and although it yielded a portion of its alkali to the acid, and became itself partly bi-carbonate, still the uric acid was not dissolved; when, however, the fluid contained only one half per cent. of alkali, the uric acid was dissolved readily enough. These circumstances would also seem to point out the propriety of employing diluents pretty freely in this colouring matter.

I shall now conclude what I have to say of that subdivision of the first class of deposits, viz. those of a strictly organic nature, by a brief notice of the colouring principle of the urine. Dr. Prout is of opinion that there exists in healthy urine two descriptions of colouring matter, one of which is capable of uniting with and imparting its colour to lithate of ammonia, which the other is not. Be this as it may, it is quite certain that lithic acid and its compounds have a greater affinity for the colouring matter of the urine than any other of the principles contained in that secretion; and, as has been before stated, the uncombined lithic acid deposit is invariably of a darker colour than in those cases in which the acid is associated with a base; but whether the colouring principle in these cases be of a different nature, or only modifications of the same thing, does not appear to be as yet satisfactorily determined;—of course, I here

leave out of the question that peculiar pink colouring matter which is so frequently found in union with the non-crystalline lithic deposits. Water is capable of removing some of the colouring matter from both these classes of deposits, and alcohol to a still greater extent; and by evaporation of either menstruum, the colouring principle is obtained in the form of a reddish-brown extract. I shall not enter in this place upon the consideration of the pink colouring matter so often found combined with certain urinary deposits, since almost all I have to say on that point is already detailed in a series of experiments, instituted in conjunction with my friend Mr. Bird, for the purpose of ascertaining whether it differed from purpurate of ammonia in its behaviour towards re-agents. The result of our experiments led us to conclude that it was a distinct colouring principle, in no respect, saving in colour, identical with that salt. An account of these experiments will be found in the Medical Gazette for July 26, 1834, and in the number for August 23, of the same year.

[To be continued.]

ON THE COMPLICATED FORMS OF VENEREAL DISEASES.

By D. Henry Walne, Esq.

In considering the manner in which "*the forms of venereal diseases are complicated with each other*," it remains to be shewn that primary venereal affections "may occur in persons already the subjects of secondary symptoms, which have originated in other primary affections no longer existing."

The carelessness and irregularity of patients in reference to symptoms which have declined, almost to disappearance, or have totally disappeared for a very short time, and sometimes their penuriousness, or their suspicion of mercenary motive in their professional adviser, induce them to proceed without advice in an imperfect and irregular course of treatment, or prematurely to discontinue all remedies, and so to treasure up the seeds of future ailment in the system.

In consequence of such neglect the constitution continues more or less under the influence of the venereal poison, and symptoms, modified by the previous treatment so as to have very qualified appearances and very uncertain periods of recurrence, are the not uncommon result. That species of practice which was generally resorted to by the adherents of the pseudo-syphilitic doctrines, not unfrequently led to such a result as is here described, and thus furnished the most numerous examples by which the doctrines themselves were ingeniously supported.

So much of mercury and other remedies having been used as would keep the disease in check, without entirely restraining and removing it, after a period of the discontinuance of these the disease puts forth some fresh and irregular, perhaps very slight, appearances; sometimes so questionable as to excite only unpleasant doubts in the mind of the practitioner consulted, at others, sufficiently unequivocal in character.

Under these circumstances the constitutional affection becomes extremely protracted, the primary symptoms in which it has originated being in the meantime very effectually cured. In this state of matters no obstacle is presented by the condition of the person diseased to the re-admission of local poisonous influence of the same kind, namely, syphilitic. Chancres are, I believe, quite as readily produced by the application of fresh infectious matter as if the person were altogether free from disease. They also are as capable of exciting buboes, and there is reason to believe that the fresh poison, if suffered to produce its effects uninterruptedly, finds the constitution still susceptible of its influence. Since no strict analogy seems to exist between syphilis and the acute eruptive diseases which originate in infection and have their limited period of existence, (for syphilis affects the same constitution repeatedly, susceptibility not appearing to be in any degree diminished by ever so many recurrences of that disease), we cannot infer, from observing its phenomena, what may be the laws which regulate its course. The local effects of poison afresh introduced during the short continuance of the constitutional influence of the infection of small-pox and of cow-pox, are much accelerated in progress, so that their advance and disappearance bear a relation to the progress and decline of the affections

induced by a previous infection still acting. It would not be right, however, to infer from this circumstance that a similar acceleration of the local symptoms, produced by a new infection in the person of one already constitutionally infected with syphilis, would take place, although I have sometimes thought that something of the kind occurs. In short, each disease having its own habits, these must be observed with care to obtain accurate information of their character.

On the subject of new local symptoms there is no difficulty in shewing that they may be produced by fresh poison, whilst the effects of a previous venereal infection continue in the constitution, and that they proceed without interruption from that circumstance, if they be not aggravated by it. This being the object of the present paper, I proceed to record an example, which is one of many, and is selected for the purpose of exhibiting, at the same view, an outline of the effects of a kind of treatment regarding which much difference of opinion appears still to obtain amongst British practitioners; my experience of the benefits of which has led me to entertain of it a very favourable opinion.

On one point in particular I am disposed to insist, when alluding to the practice of using argenti nitras as an application to chancres, which is, that so far from occasioning buboes, as some practitioners have supposed, it affords, in my judgment, the most ready and most generally successful means of preventing their occurrence. It contributes even, in some cases very evidently, quite indisputably, after the occurrence of buboes, and when suppuration seems otherwise inevitable, to their resolution, by diminishing the sensitiveness and the pain of the ulcers which have occasioned them.

Let any one observe the circumstances under which buboes connected with chancres ordinarily appear, and let him note the periods at which they begin to shew themselves, dating from that of the first appearance of the chancres from which they arise. He will find that they observe no rule as to time. That they may commence at any moment after the first symptom of chancres, but that they do not necessarily appear at all, though the constitution should become affected. That chancres may exist for weeks without producing them, if themselves in a quiet, somewhat indolent state, and if the patient be little excitable, be of temperate habits, take little exercise, and is not exposed to chill of the skin. Let him consider these circumstances, and others to which his attention will be desired when I recur to the subject of buboes, and he will see how little they depend upon the influence of the poison, taken by itself, as a cause of their origin and various states and characters. Then let him consider the means which are most effectual in causing their dispersion, as well as those which fail to arrest their progress, and he will see reason perhaps to join me in deeming the practice adopted in the following case to be desirable in many.

A gentleman who had long been the subject of secondary syphilis, which, owing in part to his own irregularity, and in part to uncontrollable circumstances, was still imperfectly cured, although all vestige of the chancres in which it had originated had long disappeared, exposed himself to a fresh cause of disease, and two chancres were produced, having the most distinct characters. He was by various obstacles prevented from seeing his medical adviser until a bubo formed, which very rapidly proceeded to a state bordering very narrowly on suppuration. In this condition he consulted me, the bubo being of a bright red colour, exquisitely tender, and softer at the middle of the swelling than elsewhere, pressure there leaving a little indentation. It was painful, hot, and throbbed incessantly. The chancres were also very painful, their margins red and hard, their cavities rather foul. My patient's constitution was naturally good, and seeing that if the irritation of the chancres were not subdued, but a few hours could elapse before the bubo would be in a state of suppuration, an inconvenience which he greatly dreaded, I applied, with the greatest attention, the argenti nitras to every part of the hollow of each of the chancres, freely, and not suffering any point of these ulcers to escape being touched. Rough usage to irritable sores as this might appear, it proved quite otherwise. Two hours sufficed for him to experience that his suffering was much relieved, not only in the soreness and pain of the chancres being less, but in the throbbing and pain of the bubo having diminished.

A spirit and goulard lotion was constantly and drenchingly applied to it, for there were difficulties in the way of leeches. A dose of calomel and opium (gr. v. and gr. i.) was given, and followed by a brisk purgative. After an interval of thirty hours the argent. nitr. was renewed, as were the internal means, and then the repetition of calomel and opium, two grains of the former, and half a grain of the latter, three times a day, commenced. For three days it was uncertain whether the bubo would suppurate or not, though the pain and tenderness were considerably reduced. Then, however, subsidence of the remaining redness, and of the swelling, began to be perceptible. Under the persevering and assiduous use of the lotion, and the regular continuance of the calomel and opium, this steadily proceeded, and the chancres began to appear cleaner. After an interval of about four days the re-application of the argent. nitr. was required, by renewed pain in one of the chancres, and some threatening uneasiness in the groin. Its effects were again strikingly beneficial, relieving both these as soon as the pain caused by its application had subsided. Proceeding with the mercurial, and regulating its quantity so as to sustain a very gentle influence upon the mouth, the symptoms of recent infection steadily and speedily disappeared, whilst the old constitutional ailments, which had been fixed by time, and only partially relieved by interrupted treatment, still required for their cure the use of efficient and somewhat varied remedies.

There is little room for comments on this case, the circumstances are so easily intelligible, and speak so plainly for themselves. The irritability of the primary sores seems to have measured the progress of the bubo, which accordingly was rapid, threatening immediate suppuration. When the tender and painful surface of these sores had been destroyed, the bubo partook of the ease which followed the application of the argenti nitras. It became amenable to the influence of a very simple remedy. The pain in it abated directly, and had entirely subsided before the calomel could act as a mercurial remedy. Uneasiness was renewed, however, when the sores became again painful, but when their sensitive surface had been again destroyed the bubo became once more easy. Its progress then ceased, and its subsidence soon followed, promoted probably by the mercurial; but no mercurial, according to my experience, would have effected it, without the aid of the application to the chancres.

The case is also conclusive as to the susceptibility of patients to re-infection locally, when still under the influence of a previous syphilitic infection.

Feb. 1836.

OBSERVATIONS

ON

THE VENEREAL PRACTICE OF BERLIN.

By Alexander Ure, M.D., M.R.C.S.
Late House-Surgeon to the Royal Infirmary at Glasgow.

[Concluded from p. 721.]

While describing the method of Dzondi, I omitted to mention, that should salivation or diarrhœa supervene, the pills are to be discontinued until these have ceased; that, in addition to the pills, the patient takes daily about a pound of decoction of sarsaparilla; that great attention is to be paid to regulate, by suitable means, the cutaneous transpiration; that the cure lasts four weeks; and lastly, that the only local applications allowed are, either dry lint or lint, spread with simple salves, merely with the view of preventing access of air and of maintaining a gentle warmth.

Before quitting this subject, I ought to state, that I was struck with the general healthful appearance of the patients, when I reflected on the excessive doses of sublimate which some of them were taking. On closely interrogating the medical attendants, I was assured that almost the only disagreeable symptom it is known to create, is a sense of uneasiness about the pit of the stomach, which is allayed by an opiate; that ptyalism is by no means a frequent consequence; and that diarrhœa is comparatively rare.

Basil Valentine, of Erfurth, who wrote towards the end of the fifteenth century, was the first who employed the corrosive sublimate internally. He gave as much as four grains for a dose, and in this practice he was followed by

the French surgeons of the time. But the energy with which these powerful doses acted, led prudent persons to consider the preparation as a poison, and to proscribe its use.

Most modern practitioners are agreed that the perchloride is a valuable remedy when we wish to make a sudden impression upon any particular symptom which is gaining ground rapidly; and then it may be administered to the extent of one-eighth of a grain, twice or thrice in the day*; but it is seldom deemed safe to exceed this quantity, for fear of giving rise to serious irritation of the stomach and bowels, to inflammation of the pleura and lungs, or to violent ptyalism, with its concomitants.

Dzondi's method, of which the chief peculiarity seems to be a connecting of the old and exploded plan with that now in practice, by supplying the intermediate links, it is certain gives rise to little or no inconvenience.

Whether it is from thus exhibiting the remedy in graduated doses that the system becomes habituated to its action, and so enabled to exert a sort of tolerance of its baneful influence when larger quantities come to be forced upon it, as is known to be pre-eminently the case with regard to tartar emetic, is at best highly problematical. Yet Lagneau, one of the principal French authorities on the subject, mentions his having been informed by a learned Athenian, that the fakirs, or Mussulman priests, in the spirit of mortification, abstain from opium eating, but substitute for the favourite oriental indulgence the sublimate, which they take at first in small doses, and gradually augment the quantity till they come to experience an agreeable excitement or exhilaration†.

A more likely way of accounting for the negative effects of the larger doses of sublimate appears to be this:—As it is a soluble salt, taken into the stomach immediately following the principal repast of the day, a variable portion of it will in no long time, by the action of the animal principles, in the secretions and accidental contents of the stomach, be converted into a comparatively innocuous compound: thus all risk of corrosion of that organ is avoided. Should any excess remain unmodified, as is soon evinced by the griping and other uneasy feelings of which the patient complains, it will in its turn be deprived of all deleterious properties by the administration of the opiate always provided against such accidents; for it is ascertained that the operation of corrosive sublimate on the animal body is almost entirely prevented by opium*.

In cases of violent salivation from mercury, Professor Kluge has found iodine to be the most powerful means of checking it. The dose is a grain of iodine in solution four times a day, increased to two grains†.

The presence of the menses, the period of utero-gestation ‡, and the supervention of hemoptoë, contra-indicate, as a matter of course, the employment of internal remedies, and suspend for a time the cure.

The treatment of gonorrhœa, balanitis, phymosis, and paraphymosis, is simple, and offers nothing deserving of notice; the former affection, as above stated, becoming seldom the subject of treatment in the hospital.

Bubo.—The inflammation of the congeries of inguinal glands, so designated, is frequently met with in females in whom no other morbid trace can be detected than a leucorrhœal discharge. Such females are for the most part of an irritable habit of body, and the discharge is of a very acrid nature. In men the buboes consequent on syphilitic sores are found to be as frequent after the internal use of mercury, as where that medicine has not been given.

As to the local management, the practice here is to open buboes very early, and that by rather a small incision. The advantage obtained is, that the smaller wound, which is much sooner filled up, heals with a cicatrice. After the incision is made, chamomile fomentations are laid on the part, and continued until the granulations have reached the level of the skin. Should,

‡ Dr. Kluge has found that syphilitic pregnant women, who had been treated with calomel, bore enfeebled and miserable children, which die soon after birth; whilst the treatment with corrosive sublimate is not attended with these bad consequences.

as sometimes happens, their continued application produce a state of local relaxation, indicated by the edges of the sore becoming pale and glazed, the granulations flabby, and the pus thin in quality and defective in quantity, then pledgets, dipped in vin. camphor., are substituted in their stead, which usually answer very well in restoring the requisite tone to the part. Lastly, the healing of the sore is accelerated, after a time, by drawing lightly along the centre a pencil of lunar caustic; over the little film thus formed a narrow slip of lint is laid, and allowed to remain until the following visit, when the application is renewed. A sort of thickish sebaceous deposit is apt to concrete around the margins of the newly-formed cuticle, which, by preventing the free access of the air, tends to keep the latter tender, and renders it liable to re-ulcerate on exposure to the slightest irritation; this, therefore, is always carefully removed, either with the blunt end of a probe, or, what answers exceedingly well, a pair of common dissecting forceps.

Where the granulations are luxuriant, the following simple mode of repressing them is sometimes pursued:—A round flattened smooth stone, weighing two or three pounds, is selected, which, being laid on the sore, is allowed to remain thus superimposed for some hours, or as long as it can be conveniently borne. This procedure is continued for some days consecutively. In many instances it is found to serve the desired end, and advance the healing of the sore; in others, again, by bruising the granulations, and irritating the surface, it does rather harm than good, and requires to be discontinued *.

* I perceive that a nearly similar practice has been inculcated by an Italian author. He recommends a large and solid compress to be placed on the bubo, and fixed by means of an appropriate bandage. This compress is to be continually soaked with some astringent liquid, and the patient confined to bed. By this treatment buboes, it is alleged, are cured in forty-eight hours, if suppuration be not present; neither is the presence of pus considered as a contraindication to its use.—Gazetta Ecclettica di Verona, Marzo, 1834.

ON THE PATHOLOGY

OF

RAMOLLISSEMENT OF THE BRAIN.

By John Gay, M.R.C.S.,

Late Clinical Clerk at St. Bartholomew's Hospital.

Of all our bodily organs, probably not one has offered more perplexities to the pathologist, in his search for the connexion which exists betwixt symptoms and disorganization, than the brain; so that after all the investigation which has been bestowed upon it hitherto, it must frequently be observed, that the greatest discrepancy appears to prevail between the indications of disorder which were observed during life, and the character of the appearances presented on post-mortem examination. Rapidly fatal results often supervene upon merely functional disturbance, without organic changes; and as often, extensive disorganization is met with, without the precedence of that long train of serious indications which we might have expected. In the pathological study of any organ, its conformation, relative situation, physical properties, intimate arrangement, and vital functions, ought to have especial attention; and I conceive that nothing has tended more eminently to mystify the nature and processes of diseased action, than its isolated consideration.

If the following observations on Ramollissement, gathered from an observation of cases of cerebral disorder in St. Bartholomew's Hospital, should not receive full sanction, yet should lead to a renewed and more successful research on so interesting a subject, the writer will feel amply repaid and honoured, his motive being rather the hope of eliciting truth than of establishing hypothesis.

On examining portions of brain in different states of ramollissement, we cannot but conclude the process to consist in a gradual degeneration of the affected portion from its primitive condition of firmness to a completely diffluent mass. In the first deviation from the healthy state, the particles appear to lose the force of cohesion which before maintained them in close apposition, and become in themselves soft, and

ultimately fluid. During this morbid change all appearances of arrangement gradually disappear, and the various structures essential to the maintenance of its vitality, nutrition, and function, become involved in the same destructive process, and are at length completely broken down and lost. A further stage (according to writers on the subject) consists in the entire separation of the softened mass from the surrounding living structure,—the formation of an excavation lined sometimes by a thin membrane,—the absorption of the fluid and reparation: of these last processes, however, I cannot speak from personal observation. This change, as will afterwards be shown, is consequent on either of two very opposite conditions of the cerebral vascular system, viz. an increase or diminution of its activity. The first, or inflammatory, may be recognized by the colour, of which there is a variety of shades, and from its limited extent. The colours may be reduced to two, "red" and "yellow," and arise from the admixture of pus, serum, or blood, in different quantities and relations, with the softened tissue of the brain itself. Sometimes, however, the redness is confined to the surrounding parts, where, on making an incision, a large quantity of bloody dots may be noticed, as if in bundles; the vascular tubes themselves appearing to have been obliterated by a process which nature has adopted to secure them against hæmorrhage. The limits are never very great, as inflammatory action set up in the cerebral substance has no tendency to spread itself far. The character of ramollissement arising from diminution in the activity of the vessels, is known by its involving a larger portion of brain, generally an hemisphere, and by its retaining its pale colour; or, as is sometimes the case, the distribution of blood being unequal, a mottled appearance is presented in the affected portion, without any evidence of an increased quantity of blood. This is an imperfect outline of the physical appearances of the several varieties of softened brain. The distinctions which have been observed have a more specific reference to another section of this paper. Taken collectively, they seem to give sanction to the following suggestions, viz. that wherever ramollissement of the brain occurs, whatever be the precise shade or situation, there the integrity of the mass is so destroyed, that its capacity for the exercise of its various functions has ceased; and being no longer co-operative with the surrounding healthy structure in the evolution of nervous energy, it becomes exactly equivalent to a portion of extraneous matter, altering the general configuration, and retarding the general actions of the cerebral system; in short, it has ceased to live. Is it probable, nay, is it possible, that such a broken-down disorganized mass can possess the necessary means of preserving its vitality? Can blood circulate,—animal heat be generated, and the nervous functions be evolved,—from a turbid fluid possessing in many instances not even the trace of blood-vessels, which are essentially necessary to the production of such results in any organ?

Here, then, are complete evidences of loss of vitality in a part of an organ analogous to mortification in other parts. The evidences of death admit of no variety, although they may be modified by external agencies. Every other morbid change in the body must be connected with active organization, although its action and results are of an abnormal nature. Another evidence may be adduced from the fact, that if a brain be allowed to remain within the skull for the space of two or three days after death, the same softened appearances will always be found. Dr. Baillie notices this in his Morbid Anatomy, where he describes the brain as assuming, after death, the character of a "pultaceous mass." But there are differences betwixt it and mortification in other parts. How may they be reconciled? They consist of a want of fœtor and the usual dark colour; the latter circumstance depends on the peculiarity of the cerebral tissue, the former on its entire removal from the agency of the atmosphere. And here I would make use of the distinction which this want of fœtor establishes between mere death of parts, and such death connected with decomposition; the first being the condition of a softened brain, the latter of a mortified extremity.

Ramollissement has been considered, from its physical signs, to be death, resulting from inflammatory action or diminished supply of blood. I shall now attempt to explain the frequency of its occurrence, and show what are the causes which most powerfully induce such a change of structure.

Excessive diminished vascular activity in any organ or texture, are well known to be capable of producing mortification; but this is comparatively seldom the case, except in the brain, where they are frequently followed by the death of the part. These two states just mentioned are the immediate causes, however induced. What, then, are the causes which predispose to such a termination, and what are their modes of operation? The following may be regarded as of most importance, viz. age; sex (the male being most liable); plethoric state of the body, especially when occurring in those whose habits are sedentary and gross; mental disquietude; suppression of accustomed evacuations; diseases of other organs, especially the heart, stomach, lungs, and kidney; and the vascular arrangement of the organ itself. Of these the last-mentioned appears to me to demand most attention, since it affords the most satisfactory explanation of the phenomenon in question. One of the most prominent peculiarities of the brain, is the security which is given it by its coverings, especially the skull. No other organ is so powerfully protected against external agencies; and this protection appears to me to hold a powerful relation to the arrangement of its vascular system. It has been said, that of all the organs in the body, the brain receives the largest supply of blood; and this may be true, taking collectively the brain and its membranous envelopes. But different parts of the organ itself have very differet degrees of vascularity. Beclard states, whilst speaking of the capillaries, that "they are more abundant in the envelopes of the brain and its cineritious substance, than in the medullary;" that "the cineritious matter of the encephalon and the nervous ganglia possesses a great number of capillaries of all sizes. The white matter, on the contrary, whether of the brain or nerves, possesses only very small capillary vessels, and in a less proportion." And in another part, speaking of relative degrees of vascularity, he classes the pia mater next to the lungs, which are the most vascular organs in the body; the cineritious matter next to the glands, and above the muscles; but the medullary between the adipose tissue and bones. Thus we see that the medullary part of the brain, where ramollissement most frequently occurs, is supplied with but a very inconsiderable quantity of the circulating fluid.

In an organized and living body, there is a constant struggle against all the powers that tend to interrupt its function or annihilate its existence. Vitality appears to depend for its maintenance, in any organ or tissue, on the reciprocal action of circulation and innervation; and for its intensity, on the degree in the scale of organization to which such organ or tissue belong: consequently, where organization is most perfect, and independent vitality most intense, there the inroads and effects of diseased action are most successfully opposed. In order to obtain a knowledge of the degree of vital energy in any part, physiologists have referred to the quantity of blood which circulates in that part, with the healthy performance of its functions, as a criterion; hence the reason why, after the removal of a limb, the person who was before debilitated and unhealthy, becomes robust and vigorous; and why parts are liable to mortify where circulation is impaired. Now the medullary part of the brain has been said to possess but a very small proportion of circulating blood, consequently its independent vitality is feeble, and the cranium appears, with its other uses, to supply the place of its inherent death-resisting principle, by defending it from numerous agencies to which other parts, from their condition of organism, may be less hazardously exposed. To this circumstance, therefore, I refer, as the reason why, in the brain, and especially in its medullary substance, a loss of vitality so frequently occurs, and why comparatively trivial degrees of vascular excitement are capable of producing it. Its vitality is languid, consequently deranged action has more power; and if the degree of disturbance is superior to the degree of resistance, and all efforts to control this disturbance unavailing, death of the part must inevitably ensue. Of the other predisposing causes, habits and age appear to have the most important co-operative influence. Every one must be acquainted with the limited power possessed by the victims to intemperance, and the enfeebled by age, to resist maladies in themselves trivial; and if other parts of the system suffer from such circumstances, how much more must a part which, in the vigour

of youth and constitutional strength, is ill able to withstand the withering breath of disease.

The immediate causes are those which are immediately capable of setting up inflammation, whether acute or chronic; or of causing a diminished flow of blood to the brain, or of causing a disturbance in the balance of its circulation: as blows on the head, tumors, extravasation, scrofulous deposits, ossification of arterial or venous tubes, pressure on their parietes, and large general depletion. I have thus hastily advanced one step further, and have shown that the natural state of the organization of the brain predisposes it to suffer greatly from any noxious disturbances; hence it is ill able to bear the excitement of inflammation; and when that process is known to have commenced, there is every reason to fear that its termination will be in the death of the part. In proportion to the degree of the inflammation will be the probability of such a result; and this probability will be much strengthened by its taking place in an individual whose constitution has been debilitated by age or intemperance. Also whilst increased activity of the cerebral circulation may thus be influenced in its termination by softening, so diminished vascular activity will lead to the same results more speedily and effectually, under the fostering influences of the two last-mentioned predisposing causes.

It is my design now to point out the symptoms of ramollissement. In the cases I have observed (regarding them from the commencement of indisposition to its close), the symptoms have been divided into two distinct classes, differing from each other fundamentally. A fear of intruding too much on the pages of the Gazette has induced me to waive the detail of cases; and I do so the more readily, as a large number of instances are recorded in the works of Abercrombie, Bright, and Rostan, which concur with my own experience.

The first class of symptoms includes a variety which are produced by inflammation itself, chronic or acute, if the disease be idiopathic; or by the specific affection of the brain, which produces the inflammation. These are obviously not of a uniform character, if we recur to the list of exciting causes; and the duration of this stage is longer or shorter, according to the degree of disturbance and other concomitant circumstances. These symptoms cannot be relied on for the production of the second series, which are ever and alone the indications of the existence of ramollissement; the probability that they will induce it being dependent (as has been before stated) on the activity of the disturbance, the age of the individual, and the condition of constitutional power. Let it be understood that the aid of many other circumstances may be called to assist in prognosticating this affection; but these appear to be the most important.

The second series are more decisive, and generally exhibit the same indications in each individual case. Their duration is protracted, and they consist of some of the following, or all combined—viz. excessive debility, delirium, coma, convulsions, stertor, and paralysis; and may be comprehended under the evidences of prostration of strength and cerebral compression. Such symptoms do not generally exist beyond a few days, being interrupted by the hand of death; although I have seen them continue twelve and even fourteen days; their aggravation daily and hourly increasing. This must be the case if ramollissement be a death of the part involved; for as soon as the mass becomes lifeless, in every instance that mass must have the same effect on the surrounding sound structure; and being to a very small degree under the influence of the healthy parts, the length of time for the succeeding changes to accrue must, in every case, be nearly equal, and the symptoms must become more and more aggravated. Dr. Bright, in his excellent Reports on the Brain, gives sanction to this view of the nature of the symptoms. Dr. B. says they are generally those of pressure, with convulsion, but goes on to state, "that neither these nor the previous occurrence of pain in the parts afterwards affected with paralysis, can be considered as essential to the softening of the brain, which is a state of the organ apparently depending on various causes;" and after citing a variety of these causes, Dr. B. says, "that partial softening owes its origin to a variety of causes, and to a considerable extent of morbid action; and we may therefore conclude, that however much the symptoms of the confirmed disorganization may approach in all cases, and generally become proofs of pressure

and interrupted nervous susceptibility and action, yet that the symptoms which mark its approach and progress will vary greatly."

If we are to attach any degree of importance to the symptomatic evidences of disease (and I conceive the study of morbid anatomy to be to its full extent useful only when combined with a minute observance of symptoms); and if the most satisfactory conclusions drawn from those two sources are those in which the least disagreement prevails, I submit that the facts already stated give some degree of plausibility to the theory now advanced; and that, in addition to what I have already suggested with regard to the nature of ramollissement, the character of the symptoms, their disagreement at one period, and their uniformity at a subsequent stage, tend to confirm these suggestions. In some cases I have observed the first order of symptoms strongly marked, indicating a chronic affection of the brain, or some part of it; but the terminating series were not indicative of the confirmed disorganization in question, and no such change has been found. But I must advance towards a conclusion.

It has been asserted by some writers, amongst whom is Dr. Sims, that this disease is reparable, and that a reparation is frequently effected. In a paper lately published in the Royal Medico-Chirurgical Transactions, Dr. S. attempts to prove such a position, and believes the facts which he brings forward "sufficient to set the question at rest, on the solid basis of pathological anatomy." After carefully reading this production (with all due deference to the talents of Dr. Sims, and disavowing any other spirit but that of defensive objection), I beg leave to submit, that although the basis of pathological anatomy is undeniably of the utmost importance, still, without the support of other auxiliaries, and especially symptomatology, that basis cannot be sufficiently firm and extensive for such a structure as Dr. Sims has attempted to raise upon it. Dr. S. confesses, that "perhaps he has to assume in this argument that ramollissement is by some means or other stopped in its progress;" and he proceeds—"if this be granted, the preceding detail of morbid appearances will readily fill up the several steps of the process of cure." Thus, on the mere appearances presented in various brains, which have been the seat of some disturbance, Dr. S. contends for the reparation of a morbid change, which he has not shewn one particle of reason for supposing to have ever existed. Surely such a condition of such an organ cannot take place without some positive signs; but in some of the cases in the paper of this talented author, where it is said to have existed, no evidences of cerebral disturbance are mentioned to have ever been observed. If the diagnostic marks of ramollissement had been cleared up, the theory alluded to would, I imagine, be placed on a much more satisfactory and substantial foundation.

As to its reparation, it appears to me that, in all morbid changes, nature provides most beautifully for their cure. This is strikingly noticed in the more obvious diseases, such as in some kinds of diseased joints, where nature appears to provide for ankylosis of the joint by a removal of the cartilage, without which the process of ossification could not be established, and the union of the two ends of bone confirmed. So in ramollissement of the brain, the fluidity of the mass which gradually obtains seems to indicate a provision for its more easy and speedy absorption; but whether such absorption has been ever permitted, by a continuance of life to a sufficient length, has never, I believe, been satisfactorily determined, and, if the theory now advanced be correct, is rendered highly improbable.

One word to the supporters of the theory that ramollissement is a disease *sui generis*, amongst whom we find many illustrious pathologists. Disease *sui generis* implies morbid action. Now morbid action has no character in common with loss of vitality. Parts undergoing such alteration possess organization and life; but the formative action is disturbed, and diseased structure is the result. But in ramollissement of the brain, all traces of circulating vessels, and other evidences of active organization, are generally entirely gone; and if the vessels themselves should not have disappeared, they present a ragged appearance, as if undergoing the changes of mortality.

Again, diseased structures may be generally injected, but no injection can be made to enter into the vessels of a softened mass of cerebral matter; it is, in fact, dead. Many of the old writers,

as Bonetus, Morgagni, in later days Drs. Baillie and Rostan, favour the theory of its being analogous to mortification, although the difference in the symptoms, and the respective duration which mark the primary affection and the terminating disorganization, have never, I believe, been pointed out.

I must now conclude these imperfect remarks on a difficult subject; they might have been much extended, but are sufficiently detailed to shew the character of the theory, and its claims to plausibility. My motive has been the hope of leading to renewed inquiries after truth on this interesting subject, deeply convinced that sophistry, however ingenious and attractive it might be made to appear, is still in every case dangerous and reprehensible. Its semblance in the garb of theory is frequently insinuating, whilst in reality it is but equivalent to the varnish of a falsehood, or the seductive blaze of the ignis fatuus. If these considerations are found to be erroneous, the writer will be the first in their condemnation; if, on the other hand, they gain consent—"si quid habent veri præsagia, vivant."

ON DOSES OF MEDICINE;

WITH SOME REMARKS ON THE

HOMŒOPATHIC SYSTEM.

By Dr. Leonard Stewart.

Read at the Westminster Medical Society.

To prescribe a dose of medicine is considered by the unsophisticated as the most obvious and simple part of our professional duties; and we continually see those who shrink from all investigation into the nature of disease, step forward as the most confident in proclaiming the virtues of remedies, and putting in practice what *they* consider as nine-tenths of the healing art, and what *we* call polypharmacy!

It requires not much experience nor much reflection, however, to convince the faithful practitioner of the natural predominance of scientific pathology over therapeutics. In important cases, a thousand circumstances are to be borne in mind, a thousand contingencies glanced at, in the rapid manner which habit makes familiar, before matters are at all prepared for a fair experiment: for I consider every first administration of a dose of medicine an experiment, rendered, however, more or less clear, rational, and satisfactory, by studying before-hand the indications for its employment, and by striking out, as much as we can, what may obscure or obstruct its effect.

Nothing tends so much to rectify our notions about the power of doses of medicine as the study of pathological physiology, or, in other words, of the natural history of diseases. This at once presents us with three *practical* divisions into, 1st, diseases which cure themselves; 2dly, diseases which are cured or influenced by treatment; 3dly, incurable diseases. I do not pretend to show the proportion in which they all stand. I am quite aware that these three classes are not distinctly separated—that very many begin with similar phenomena—that we continually see cases which pass from one stage into another. Thus a catarrh, or a cut finger, may become a serious, or even fatal, disease. So also an ague or an inflammation, though at first showing the usual and *normal* symptoms, will at times gain or lose its intensity; there being occasionally an *under-current* at work, which embarrasses our judgment, and sweeps the patient on to health, or dissolution: and lastly, the records of medicine are not wanting in examples of the most extraordinary recoveries from maladies which, by common consent, have been considered hopeless. Still, although the only sure appreciation of the fatality of diseases is retrospective, the accumulated experience of the profession has elucidated the relative strength of nature and of art, of diseases and doses of medicine, much more accurately than the uninitiated are ready to allow; and it may safely be asserted, that for one instance talked of, which has puzzled the skilful practitioner, a hundred, a thousand, are forgotten, in which he has been sufficiently close in his judgment.

While, then, any person of good sense and good faith applies *only* the subordinate or *ancillary* parts of our art to a vast share of cases, he reserves the employment of active or *heroic* remedies (as they are called) for those conditions which are important but not incurable—which would be fatal, or become chronic, if left alone—in which,

after all has been arranged that prophylactic, dietetic, palliative, and chirurgical medicine can do, there yet remains to be done *something more*

This "something more" is, with many people, a very simple matter. The plan of universal medicines is the most obvious, and at once recommends itself as abridging or superseding all those tedious intricate occupations and exercises of the faculties called the medical sciences; the whole cumbrous details of which are exchanged for an easy and agreeable routine!

What a pity, then, that a method so admirably fitted for getting rid of the Doctor should not have equal potency with reference to the disease: but perhaps it is too much to expect a double effect from any attempt so single and so *simple!*

I would be understood as speaking without "respect of persons," and as condemning at once the blue-pill plan, the Morison-pill plan, the bread-pill plan, or any other undiscriminating plan, which pretends to reduce to uniformity what is in its nature infinitely varied and complicated. I consider a due variety of remedial measures (under the personal direction of the medical man) as the distinguishing mark of rational practice.

But we find, that even after allowing a choice of means, there have been very opposite ends proposed in their employment.

The contra-stimulant and Homœopathic systems stand remarkably contrasted; not only as to their increasing and diminishing the dose of medicine, but also from there being, in the first plan, very little regard paid to the phenomena and symptoms produced by the remedies; in the latter, the affectation of a great deal more than usual. The disciple of Rasori brings his powerful remedy, and lets it grapple with the antagonist disease, and conquer it in a close and mysterious embrace; there being no physiological effects, and little inquiry into details. It would, however, require a good deal of time, and would yield no new information, to dwell upon the very extraordinary statements of the contra-stimulant school. I need not remind you of the comparative neglect into which the doctrine has fallen; indeed I do not know of much that has been retained, besides the administration of emetic tartar in pneumonia; and here it is not used in the large doses once talked of.

Homœopathy (as we are made acquainted with it) comprehends not only the imitation of disease, but the diminution of the dose of medicine. With regard to this ingenious supplanting of disease, as recommended by Hahneman, I cannot help thinking that (coupling with this design the extremely small and microscopic means by which it is attempted) there generally exists a delusion; the copy existing only in the mind's eye, while the reality is going on uninfluenced by the phantom of physic which is to frighten it away. We have heard of a figure of real flesh and blood passing for a very good portrait; and so it may be with these factitious pseudo-maladies. Looking, indeed, at the liberal allowance of time which is made (often from a week to a month between the doses), and calculating the comparative and relative agency of the elements of a Homœopathic case, I conclude that it is not the small dose of *medicine*, but rather the large dose of *time*, which works the miracle. In this way we can account for the long-continued operation assigned to these very minute doses, which otherwise would be one of the most staggering parts of the scheme. This alliance between the dwarf and the giant may make the last day of the week, or month, as energetic as the first.

I need not tell *you* that, as far as the mere principle of homœopathy, or the plan of treating *similia similibus*, goes, there are many examples of this which are not new. Many have cured diarrhœa with purgatives, scalds and burns with stimulants and rubefacients, gonorrhœa with irritants—nay, one has heard of sailors cutting short an old gleet by contracting a fresh clap, which is in *practice* strictly homœopathic, to say nothing of their *principles*. But this is surely a very different thing from singling out a part or individual symptom of a disease, and attacking it exclusively by an infinitely subdivided dose of medicine. You will find, in one of the Italian books on Homœopathy (under the head Vertigo), a distinction made of six different modes of falling down, with six or eight separate remedies for each kind of fall, besides other drugs for all the other symptoms! I think, then, I am justified, not only in questioning the propriety of encouraging, in all cases,

rather than checking, the natural symptoms of disease, but also in doubting the mere facts; in denying that the phenomena which are said to be produced by the homœopathic doses are in reality attributable to them; indeed, in some cases, in absolutely denying their existence.

Placing this criticism, then, merely on the ground of the existence or non-existence of the facts, I care little about the name of quackery, which is often mixed up with this and other doctrines. We have, I think, a simple way of deciding this point: by asking—is any part of this or that system concealed, or is it laid before the profession in a fair and manly way, open to inquiry and experiment? The essence of quackery I consider to be mystery and concealment: whatever else of error, enthusiasm, and imprudence, mixes up with these questions, is a matter of much less consequence, because all this soon rectifies itself.

We thus fall back upon the more sober quiet method of employing ordinary doses of medicine, upon the plain ground of analogous circumstances, and experience in former cases of their remedial power. Without generalizing too much, or taking aim at each symptom,—without too close attention to those elective affinities, if I may so speak, which determine certain local, specific, physiological, and pharmacological phenomena upon the exhibition of most drugs,—we regard their general curative agency. And while attentively watching and controlling their operation, do not forget that the whole affair is one of fact and observation, and not capable of systematic minuteness and exactitude.

That many clever fine-drawn transcendental systems may be indirectly useful, by superseding blind perseverance in gross mechanical mischievous practice, I mean not for a moment to deny, but I am now reviewing the true principles, and not the mere expediency of the plan, I have mentioned.

I shall not now be expected to go into a detail of common-place cases which have been treated in the usual way, nor to deduce the well-known doses of mercury, opium, bark, &c., which are laid down in the familiar manuals.

The medical world seems, in the present day, to follow, with regard to all systems, the practice of Frederick of Prussia with the philosophers whom he invited to his court. His boast was, that he knew how to squeeze the orange, and throw away the pulp I do not know a better system-squeezer than a medical society; but we cannot always obtain much juice!

But notwithstanding I have here declared the personal superintendence of the medical man to be of more importance than any thing else, and have considered the virtue of the healing art to consist, not in the doses of medicine alone, but in the dexterity with which they are used, I am very willing to be told that I am in the wrong. I shall be much edified by the discovery of any *short cut* to remedial skill, which will save me the trouble and responsibility of attending to diagnosis and prognosis.

I am quite ready to employ the largest doses or the smallest, to go to Brobdignag or Lilliput, or to give no physic at all, if I can be convinced that there is good reason for so doing.

I am quite sure that the suffrages of the rising generation would be secured by diminishing or suspending the dose; and as for those "children of a larger growth" who are always craving for doses of medicine, while time only is required, I am willing to take lessons in

> "—— the art of amusing the patient,
> While nature cures the disease."

ON THE TREATMENT OF HYDROCELE BY SETON.

To the Editor of the Medical Gazette.

Sir,

In your Gazette of the 30th of last month, there is related in the analysis of the "St. Thomas's Hospital Reports," some observations by Mr. Green, surgeon to that hospital, on the treatment of hydrocele by seton; and as it seems to imply a claim to originality in the mode of management, I beg leave to request you will be kind enough to make room in your next number for the following extract from my book on Hydrocele, p. 20, &c., published in 1825, by T. and G. Underwood, Fleet-street.—I am, sir,

Your obedient servant,

James Holbrook, M.D.

Crickhowell, Breconshire,
14th Feb. 1836.

"As I could not learn from the history of the cases treated by seton, that in any instance suppuration had occurred within the sac, but that the cure was performed on the common principle of exciting adhesive inflammation, it appeared to me as quite unnecessary that the seton should remain in for twelve or fourteen days, as it not only rendered the operation much more tedious, but also increased the risk of suppurations and abscesses taking place in the cellular substance of the scrotum. The only object, therefore, to be derived from the seton, was the producing of a certain degree of inflammation; and as that object appeared in most cases to be obtained in about three days, or *sometimes sooner*, I was of opinion the seton ought then to be withdrawn. But to this there was the objection, that it frequently contracted some adhesion to the tunica albuginea, which rendered the early withdrawing of it painful. In order to obviate this objection, it occurred to me that the introduction of a smaller seton would have that effect, and at the same time be capable of exciting a sufficient degree of inflammation; and in this opinion I was strengthened from learning that Mr. Pott had, in the latter part of his life, used but a very small seton.

"Bearing these circumstances in mind, I determined the first opportunity that might occur to operate on those principles, which, although founded on the operation by seton, would in many respects be essentially different, and the troublesome and complicated mode of int oducing it by means of a second and longer canula, passed through the canula of the trocar, together with the long needle having a moveable point, as recommended by Mr. Pott, be rendered unnecessary. A case, fortunately, soon presented itself, and I operated in the following manner:—

"Having discharged the contents of the swelling by means of a common trocar, I grasped the scrotum, together with the loose tunica vaginalis, with my fingers, close to the testicle. This being done, and an assistant holding one side of the skin, in the same manner as in making a common seton, I at once passed a straight suture needle, armed with a common ligature, through the skin, the scrotum, and tunica vaginalis, &c.

"On the following day the scrotum began to swell and inflame, and the testicle was enlarged and painful.

"On the 4th the thread was withdrawn.

"The cure was accomplished in about three weeks."

Page 30:—"Should any difficulty be apprehended in being able to pinch up the tunica vaginalis with the scrotum, in order that the needle may pass properly through the sac, a probe may be introduced through the canula into the sac, which can be used as a guide in pinching up any part of the tunica vaginalis that may be considered necessary."

Page 29:—"In children I have always found a single thread of silk sufficient."

CASE OF HYDROPHOBIA;

WITH THE POST-MORTEM APPEARANCES.

To the Editor of the Medical Gazette.

SIR,

SHOULD you deem the following case worthy of notice, I shall feel obliged by your inserting it in your valuable periodical.—I am, sir,

Your obedient servant,

FREDERICK PRITCHARD.

57, Dorset-Street, Salisbury Square,
Feb. 12, 1836.

In the latter part of October last, Joseph Robbins, a robust healthy young man, æt. 20, residing at Shottery, near Stratford-upon-Avon, Warwickshire, was bitten on the thumb by a strange dog. It appears that the man was in a neighbour's house, when the dog entered; and upon his attempting to secure it he was bitten in three places. The dog escaped, and from subsequent inquiry there is no doubt but that it was in a rabid state.

Robbins took no notice of the wounds, but followed his usual occupation, which was that of a boatman. In the course of a week the parts cicatrized, and he remained perfectly well until about 7 o'clock on the morning of Tuesday, the 12th of January, being a period of ten weeks from the time he was bitten. In the afternoon he walked from Stratford to Shottery, a distance of one mile, and on his road he called upon his sis-

ter. He complained to her of great indisposition, and requested that he might have some food. She wished him first to wash his face and hands; but he replied, "*that the wet cloth would choke him.*"

Soon after this my brother, a medical practitioner at Stratford, was requested to visit him, which was about five o'clock in the evening. He found him oppressed with anxiety, and complaining of stiffness and constriction about the throat and chest. The pulse and general temperature of the skin did not at that time vary much from their natural state. The respiration was hurried, and interrupted by sighs. My brother observing these symptoms, offered him some tea to drink; but the moment the fluid came in contact with his lips, it brought on a violent convulsive paroxysm, which seemed almost to threaten suffocation, and he dashed the cup from him.

The patient, on being questioned whether he had been bitten by a dog, answered in the affirmative, but did not betray any alarm. There was no uneasiness or stiffness about the thumb, and the cicatrices were of a pale colour. My brother being satisfied as to the nature of the disease, sent to inform me of it; and I, together with two medical friends (who were at Stratford at that time), met him there shortly afterwards. We agreed to bleed the patient, and to administer large doses of opium combined with calomel, and to employ the mercurial inunction; but the parents, as well as the man, obstinately refused to allow us to resort to any means for his relief, and we were in consequence obliged to leave him.

Early on Wednesday morning we again visited him, in conjunction with my father, and found all the symptoms aggravated in the greatest degree. He had dressed himself, and was down stairs walking to and fro. There was an appearance of horror and despair in his countenance beyond description; his eyes were wild and glassy; his mouth was filled with a viscid saliva, which he was perpetually endeavouring to spit away from him in every direction, in the most impatient manner. His pulse was quick, and his aversion to fluids as well as solids was greatly increased; even the name of either would cause great disturbance; also the sound of any fluid being poured into a vessel. The simple agitation of the air by the opening of the door, or even the breath of a person, would bring on a paroxysm of general convulsions. We placed him in the erect position, and bled him largely, hoping to make some impression upon the system; and also rubbed a considerable quantity of the unguentum hydrarg. fort. along his spine, and upon his arms.

At eleven A.M. Dr. Thomson, of Stratford, saw him, and suggested that a tobacco enema should be administered; but the moment he heard the gurgling noise in its passage up the rectum, he darted from us. Dr. Conolly, of Warwick, also visited him in the afternoon; but the patient's sufferings at that time were so great, that he would not permit us to approach him; and in consequence of his escaping into the village, it was found necessary to confine him with a strait waistcoat; after which the extract of belladonna was applied to the external part of the throat, but without any beneficial effect. The paroxysms continued unabated until one o'clock on Thursday morning, when he appeared worn out; and half an hour afterwards he expired calmly, at the distance of forty-two hours and a half from the time of his feeling unwell. The patient never lost his senses throughout the attack, but talked of the certainty of dying, and wished to see all his friends; but he did not allude in any manner either to the dog or to the part which had been bitten.

AUTOPSY.—*Cavity of the Cranium.* Upon removing the calvarium, and examining the sinuses of the brain, we found that they were gorged with dark-coloured blood. There was effusion of serous fluid between the arachnoid membrane and pia mater, and also an effusion of about an ounce of fluid in the lateral ventricles. The choroid plexus in each lateral ventricle was of a dark colour. The substance of the brain was natural in most parts, excepting the medulla oblongata, which was more injected than usual. Upon exposing the theca vertebralis, it was found highly vascular and injected; and also the pia mater, but not to so great an extent. The medulla spinalis was in a very softened state throughout its whole course.

Throat, chest, and abdomen.—The mucous membrane lining the larynx, trachea, and bronchiæ, presented a dark congested appearance, resembling black jelly. The substance of the lungs was very much congested. There was no vascularity about the pericardium, neither was there more fluid than usual. The external part of the heart looked paler, and felt softer, than natural; but the lining membrane was congested in the same manner as the lining membrane of the trachea and bronchiæ. The pharynx and superior part of the œsophagus were of a pale colour; but towards the inferior part, near the cardiac orifice of the stomach, patches of extravasated blood were seen, and also the same appearances towards the pyloric orifice. The serous membrane investing the stomach and intestines was in several parts a good deal injected. The liver, spleen, pancreas, and kidneys, were all of them of a leaden hue throughout; and the bladder was collapsed and perfectly empty.

PREMATURE VACCINATION.

To the Editor of the Medical Gazette.

Sir,

In a former number of your journal I have asserted that no child ought to be vaccinated during the period of lactation, by which I mean during the first nine months; in confirmation of this statement the following report may perhaps serve as an example:—

Mr. Als had three daughters vaccinated, the eldest and youngest before the sixth week, the second not until she was a year and a half old. About three years ago the eldest had the small-pox very severely, was nursed by the second sister, who escaped it. About three weeks back I re-vaccinated the second and youngest. The cow-pox in the youngest ran its natural course; the patient laboured under considerable febrile action from the eighth to the twelfth day. In the second sister it appeared to rise regularly till the third day, and then died away. The eldest is now about thirty, and the youngest about twenty years old.

I lately saw four children who had been inoculated for the small-pox: only one of them had been vaccinated. She had between thirty and forty pustules; the other three were very full. On inquiry, I learned that the child had been vaccinated before it was two months old.—I remain,

Yours most respectfully,
John Grantham.

Old Crayford, Kent,
Feb. 9, 1836.

REMARKS ON COMMON, MODIFIED, & SPECIFIC SENSATION,

PARTICULARLY WITH REFERENCE TO THE SENSE OF TASTE.

To the Editor of the Medical Gazette.

Sir,

From the whole tenor of Mr. Bishop's communication, inserted in the last number of the Medical Gazette, I can only think that we do not rightly understand each other. It appears to me that we are verging upon a controversial discussion without having previously determined the exact sense in which *terms* are to be employed. To avoid (so far as I am concerned) all possibility of mistake, I will define what I have meant, and mean, by "common sensation," a "modification of common sensation," and a "specific sensation;" and the definition which I am about to give will be found, I believe, to accord with what physiologists ordinarily understand by these terms.

Common sensation is that general sensibility pervading the whole of the external surface of the body, and, to some extent, almost the whole of its structure; and is illustrated by the simple notion of *resistance*. The *modifications* of common sensation include the various impressions furnishing the mind with its ideas of the hard, the soft, the rough, the smooth, the painful, the titillatory, and so on. The perception of these different impressions is common to every structure possessing common sensation; and when, from any cause whatever, the impression of simple resistance is not communicated to any part by the contact of a tangible object, no ideas of the rough or the smooth, the hot or the cold, or any other mode of common feeling, will be received through

the affected medium; and hence these perceptions are regarded, not as distinct senses, but as modifications of that sensation *common* to most of the tissues of the animal economy. *Specific* sensation implies the perception, through some special medium, of impressions originating notions of the qualities of objects not perceptible through any other; as the eye, for example, is alone the medium of the *veritable* perception of colours, the ear of sounds, and so on.

Now if I understand the argument of Mr. Bishop correctly, he would refer the operation of all the senses to a modification of common sensation; and would, in this respect, regard "taste" as holding precisely the same relation to ordinary feeling as "sight," "hearing," and "smell;" and therefore a modification of common sensation. I must here respectfully submit to Mr. Bishop that this is conceding the whole question; for what is the position that I have wished to establish? Why, that "taste" is as independent of common feeling as the rest of the senses; and that (as in the case of sight, hearing, and smell) we must look for a *special* nervous provision. No axiom in physiology can be better established than that one nerve, if simple in its origin, subserves the performance of one function only; and hence, to prove the independence of any function, is either to overturn the above axiom or to create a necessity for "seeking a separate nervous supply."

I do not undertake to declare, or even to suggest, in the absence of any facts, what is the nerve of taste; only this I contend, that the nervous filaments supplying the tongue and palate with common sensibility—that is to say, with the power of perceiving the hard, the soft, the hot, the cold, the rough, the smooth, and so on—do not endow those structures with the capacity of appreciating the bitter, the sweet, the sour, the saline, and the like qualities. Here, in the publication of the cases relating to this subject, "I *have* abstained from expressing any *mere* views, and confined myself to the fact, and the suggestion of what appeared to be the legitimate induction." In other words, I have, without *comment*, established the premises, and then suggested the proper conclusion to be drawn from them.

I must differ from Mr. Bishop with regard to the inference fairly deducible from his own published case. Because "taste" and "touch" in the tongue were both abolished, coincidently with destruction of the lingual branch of the fifth pair, it certainly is not, "*therefore*, quite unnecessary to look for a separate nervous supply." For if the lingual branch of the fifth pair of nerves *do* endow the tongue with its peculiar faculty of "taste," it may, like the symmetrical nerves of the spine, be a compound nerve; and as these latter comprise filaments both for motion and sensation, so may the lingual branch of the fifth pair include separate filaments for common and for specific sensation; in which case there would most unequivocally be "a *separate* nervous supply." And, indeed, this too is most distinctly admitted by Mr. Bishop, where he states,—"the nerves of the fifth pair doubtless contain *filaments specially modified for the purpose of taste also;* and as compound nerves derive their origins from separate portions of the central mass, it is not at all surprising that one portion of the nerve may be paralyzed without implicating the other,—a circumstance often illustrated by paralyzed parts possessing either motion without sensation, or sensation without motion."

Mr. Bishop has most certainly admitted every thing which it was the object of my papers to prove.

I have the honour to be, sir,
Your obedient servant,
DANIEL NOBLE.

Manchester, Feb. 9, 1836.

MEDICAL GAZETTE.

Saturday, February 20, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

ON SOME RECENT INQUIRIES CONCERNING INSANITY.

FEW things connected with the administration of justice in this country must seem more anomalous, to those who quietly reflect upon them, than the proceedings that take place at lunacy in-

quests, instituted under the authority of the great seal, and those which casually occur before coroners, and on trials for criminal charges. The length of time devoted to the investigation of cases of the former description, where the disposal of property is chiefly concerned, contrasts strongly with the haste in which the other questions are settled—though involving, in general, decisions respecting life or death.

The case of Lady Kirkwall, which has just closed, is a good example of what takes place in civil cases. Here was a commission of lunacy held in order to ascertain the soundness, or unsoundness, of mind of a lady, whose actual state for some years since, upon the slightest inquiry, could scarcely admit of question. Eight entire days were spent in the investigation of all the facts which had, or were supposed to have, any relation to the subject—accumulation of evidence, even to the most extravagant redundancy, was adduced—and several thousand guineas were expended in fees to commissioners, counsel, witnesses, and all who had any pecuniary claim, interest, or concern in the transaction.

Put the case that Lady Kirkwall was on her trial for some alleged criminal offence: how differently, in the manner of its investigation, would the whole affair have been disposed of! The result, no doubt, so far as the finding of the jury, would have been precisely the same; for no twelve men, however plain their intellects, could fail to come to the identical conclusion arrived at, after eight days' deliberation, by the three-and-twenty special jurors engaged in the late inquiry. The facts to be appreciated were strikingly simple and obvious; and one only wonders that half an hour should not have been sufficient to form a judgment of their import. The insanity of Lady Kirkwall clearly involved a derangement both of the intellectual and moral powers. Her mind was highly cultivated in early life, and the beautiful letters written to her children, many years ago, excited the admiration of all who heard them read in court. In 1803, she gave birth to the present Earl of Orkney, and afterwards to his brother the Hon. Col. Fitzmaurice: but for several years she has persisted in denying that they are her children, although in their infancy and boyhood she always behaved to them as the fondest of mothers. In this respect, surely, there is the most evident proof of a complete subversion of the moral—the natural, feelings. Again, she holds that her husband the late Lord Kirkwall, who was separated from her in the year 1810, and died in 1820, is *not* dead; but that she sees him frequently, and that he and others are in a conspiracy against her liberty and life. Also that the late Countess of Orkney, who died in 1831, is not dead—although she was even present at her funeral. Other instances of manifest lesion of the powers of her mind are found in the somewhat ludicrous facts—that she has had no less than *twenty-five cats* at a time lodged in her bed-chamber, and treated as valued guests—that she has fancied she smelt poisonous gases puffed through the walls of her apartment—that she has been more than once shot at in the street, and stabbed in the back, &c. In short, as Drs. Monro and Macmichael, who were examined, said—never was there a more complete case of insanity made out. The unfounded suspicions of poisoning and conspiracy, the unreasonable aversions, and equally gratuitous attachments, which she had exhibited, were perfectly characteristic and decisive as to the nature of the mental disorder with which her ladyship was affected.

Now all this, one should have thought, might have been gathered in the shape

of legal evidence in a very short time: but no; eight days, and the expenditure of large sums of money, were deemed essential, before the very simple verdict could be returned—that Lady Kirkwall was of unsound mind, incapable of managing her own affairs, and had been so since the year 1831.

Of the mode in which inquiries of a like kind are despatched, when criminal charges have to be considered—even in instances where the proofs of insanity have been beyond all comparison more delicate and precarious—we cannot adduce a better example than that which occurred some few months ago, in the case of Stanynought. This unfortunate man, it will be recollected, took away the life of his child, whom he fondly loved; but though there was no proof of his labouring under any delusion—no evidence, in fact, of his intellects being disordered antecedent to, or at the time of, the commission of the fatal act—he was speedily acquitted of the charge of murder, on the ground of insanity, and consigned to an asylum for the insane. His subsequent suicide must remove any doubt that the unhappy man was affected with a species of moral insanity; but certainly, at the time the case was so summarily disposed of, misgivings might be, as they were, entertained as to the real nature of the circumstances. It is, perhaps, not too much to say, that had the mental state of Stanynought been made a subject of inquiry before lunacy commissioners, as it might have been had property been at stake, and the overt act of his alleged disorder not involved the question of criminal responsibility, it is not unlikely that it would have occupied much time, and created a large expenditure in the investigation. So much for the difference recognized in this country between criminal and civil cases.

Let it not be supposed that we are advocates for an undue haste or precipitancy in inquiries of this nature: we merely express a doubt of the fairness of spinning out investigations relative to the disposition of property, while the grave question of criminal responsibility is so summarily despatched. In the case of Stanynought, to which we have just alluded, we believe that the decision, however rapid, was right: but we are full well aware that there was a chance also of its being wrong. In but too many instances, we fear that the practice of leaving to a common jury the determination of the question of soundness or unsoundness of mind, has been attended with lamentable consequences. The case of the man who murdered Mr. and Mrs. Bonner, in Kent, some years ago, must be fresh in the recollection of most readers. The state of derangement under which he laboured was much less obscure than that of Stanynought: he had no delusion whatever—no motive of revenge or avarice for what he did: the master and mistress who fell victims to his sudden and ungovernable desire to kill them, had always treated him with kindness; and to the last the man was unable to give the least account of what had happened, further than that he supposed he must have been prompted to it by the devil. Yet he was executed. The verdict of the jury in Stanynought's case would almost induce us to believe that had this decided instance of homicidal monomania occurred very recently, the catastrophe would have been averted. But it is difficult to speak with any degree of certainty, when the verdict of a jury is proposed as a problem. There is great difficulty, even to the best-instructed minds, in forming a right judgment of many of the common cases of insanity which are met with. The difficulty amounts to danger of an awful kind, when not the seclusion of the subject, but his life or death, is matter of deliberation—his

fate placed in the hands of twelve indifferent persons, who have most probably never given any attention to the manifestations of diseased mind.

The only hope of obviating fatal errors that may arise from this source—of preventing, in fact, judicial murders—is placed in the possible spread of information. We would fain believe that something of this kind has been already effected, and that good has come out of much evil that has been done. At all events the discussion of insanity cases, as often as they come before the public, must, we think, be attended with decided advantage; and it is with that view that we generally conceive it to be our duty to call to them the attention of our readers.

Before we lay aside our pen, it may be as well to mention that a very remarkable case is even now, or has been very recently, a subject of deep interest to the French public, and particularly to the psychologists. We allude to the *affaire* Riviere, in which the accused, a young man of 20, who by all accounts never enjoyed a fair proportion of reason, slew his mother, sister, and brother, and was in consequence condemned to death. But it is thought that a strong representation of the real nature of the circumstances, drawn up by Esquirol, Orfila, Marc, and other distinguished authorities in questions respecting mental derangement, will have the effect of procuring a commutation of the sentence. We may possibly recur to the particulars of this case at another opportunity.

NEW METROPOLITAN UNIVERSITY.

We stated in our last number that it was to Mr. Warburton, in conjunction with the Ministers, that all interested in the subject must look for the new arrangements about to be adopted with respect to the medical profession. Since then an evening paper has published what follows, on the authority of the gentleman above mentioned, and which both corroborates what we said last week, and also affords us some important details on one point in the intended charter. By the by, we were rather amused to observe that Mr. Wakley's grand *coup*—that of gaining some information by questioning Mr. Spring Rice in the House of Commons—totally failed; that right honourable gentleman, though due notice had been given, not thinking it worth his while to be in his place to answer him.

"Edinburgh Town Council, Tuesday.—A letter from Mr. Warburton, M.P., in answer to a letter from the Lord Provost, was read, in which he assures the Council that no one could be more anxious to prevent the establishment of any new monopoly of teaching, and to see instituted some uniform system of medical instruction and examination, to serve as a basis for granting to persons properly instructed and examined the enjoyment of equal professional immunities in every part of the United Kingdom. Whether such a plan could be carried into effect by means of any Crown charter, might reasonably be doubted. He thought government would scarcely be justified in delaying to constitute the proposed new University of London, for the purpose of maturing beforehand, and incorporating with the scheme of that university, a comprehensive measure of medical reform. The Government, he thought, should constitute the new University, investing it with all the privileges appertaining to such institutions, reserving to itself the power of modifying its laws and ordinances, so as to render them generally consonant to any general plan of medical reform that may hereafter be approved of. Except upon certain points, he was not informed of the details of the proposed plan. *The most important that he was aware of, as affecting the interests of medical schools in general, was, that no medical school whatever was mentioned in the charter by name.* A matter of importance for which the London University was contending was, that no teacher of any medical school, and no medical or surgical officer of any hospital, shall be a member of the Board of Examiners."

PROCEEDINGS AT THE CROWN AND ANCHOR.

WE this week publish (see p. 832) another protest, from one of the largest of our metropolitan schools, against the late irregular proceedings of the Meade-and-Wakley meeting. The number of signatures is *one hundred and ninety-seven.* We congratulate those gentlemen who have thus manfully come forward to clear themselves from the imputation of being in any manner connected with the agitators.

MEDICAL EDUCATION IN DUBLIN.

THE SCHOOL OF PHYSIC.

THOSE of our readers who take an interest in watching the signs of the times, and in observing the setting of houses in order,—which is just now the occupation of most of our medical establishments, preparatory to certain anticipated changes,—will probably be not a little amused to learn how such things are managed in the sister kingdom, and more particularly in what is called the *complete* School of Physic in Ireland. The latest intelligence we have received from that quarter apprizes us that *surgery* is no longer deemed requisite to be taught in the University of Dublin: there is, indeed, a professor of surgery attached to the institution, but his office has been rendered this season a sinecure —himself and pupils being put under a ban prohibiting them from following surgical pursuits any longer. We must enter into particulars regarding this curious affair.

Until the year 1832, it was customary for the Professor of Anatomy and Surgery (Dr. Macartney) to teach both branches of medical knowledge in one and the same six months' course, devoting, we believe, a certain portion of that course specially to surgery. But in the year just mentioned, some new Edinburgh regulations were issued, rendering it necessary that surgery and anatomy should be taught in distinct and independent courses, five lectures a-week being given to each. With this the Dublin professor complied, at considerable inconvenience to himself, it being an object, for the benefit of the *complete* School of Physic, that it should be so ordered as that its students should be qualified to take degrees in Edinburgh. Dr. Macartney procured from the University authorities leave to lecture four days a-week, at three o'clock, in addition to his daily lecture at one. This system was pursued steadily for three years, when suddenly the three o'clock surgical lecture was forbidden, and that under such extraordinary circumstances as, in spite of the suicidal mischief done to the school, to render the transaction highly ludicrous. *The doors of the theatre were shut in the faces of both the Professor and his pupils.* It may be asked—is this credible? We can only reply, that the *fact* is vouched for by the following correspondence. The first two letters, it will be observed, were written in 1832, preparatory to opening the winter session: the rest of the documents are recent.

From Dr. Macartney, to the Provost of Trinity College.

My dear sir,—Some regulations were made last year in Edinburgh, by which no course of anatomy or of surgery will in future be recognized as such, unless the lectures be delivered *five* days in the week, during the winter six months.

I do not think this time too great to devote to subjects of so much importance: but if it were otherwise, our school would lose credit by not furnishing as full courses as are expected elsewhere; and the interests of all the professors, as well as mine, would be seriously injured, if the numerous class of medical students that graduate in Edinburgh should be compelled to obtain their qualifications in anatomy and surgery in any school except our own. Much inconvenience has been always experienced both by myself and the students, by having only *one* hour in the day allotted to two courses of lectures (anatomy and surgery), each of which is a subject of greater extent than those taught by the other professors.

I have been obliged, hitherto, to detain the pupils in town after the medical session, and lecture sometimes three times a-day; and even so, have not satisfactorily terminated my lectures. I should add, that I am at present necessitated to give on surgery a *shorter* course than any other on the same subject in the United Kingdom, or, I believe, in Europe. Under all these circumstances, I only wait the sanction of the board, to prolong my courses to the necessary extent; and I shall be much obliged by your bringing the matter before the board, if you can, before you leave town, as the time has arrived for making the winter arrangements.—Yours truly,

JAMES MACARTNEY.

Sept. 28, 1832.

From the Provost, to Dr. Macartney.

My dear Doctor,—The board has agreed

to sanction your proposal of lecturing at three o'clock, *four* times a week, in surgery, in addition to your lectures every day in anatomy.—Yours very faithfully,

BAR. LLOYD.

Provost's House, Sept. 29, 1832.

Now mark the change that took place on the opening of a fourth session.

To Dr. Macartney.

Sir,—I am directed by the board to communicate to you their order of this day, which is as follows:—Ordered, that Dr. Macartney shall not lecture at the hour from three to four o'clock—that hour having been already assigned to another of the professors of the School of Physic.

I am, with much regard,
Your very humble servant,
ROBERT PHIPPS, Registrar.

Trinity College, Oct. 13, 1835.

" Resolved by the board, that this order be communicated to the King's and Queen's College of Physicians, through their Registrar.

The aforesaid order having been violated, it is now further ordered, *that the doors of the Anatomy House shall be closed from three to four o'clock every day.*

By direction of the board,
ROBERT PHIPPS, Registrar.

Nov. 28, 1835.

From Dr. Macartney, to Dr. Phipps.

Sir,—The enclosed Memorial was prepared and signed by a majority of the class attending me; and would have been signed by all (except three or four, who are not seeking information, but the technical qualification of a certificate), when a report was heard, that those pupils should be fined who should sign any memorial.

I therefore send the copy of the one adopted, for the inspection of the board; and beg to know if the Memorial will be received with the signatures of the pupils, without visiting them with any blame.

I am, sir,
Your obedient servant,
JAMES MACARTNEY.

Dec. 4, 1835.

The Memorial of the Students of Anatomy and Surgery in the University of Dublin, to the Provost and Board of Trinity College.

Your memorialists beg leave to state, that they are medical students, attending the lectures on anatomy and surgery in Trinity College; and that many of them have come from England, expressly for the purpose of studying anatomy and surgery in the University. The greater number of your memorialists are matriculated students; but not being students in arts, are precluded from taking a medical degree here, and are preparing themselves for graduation in the University of Edinburgh, or for the diploma of the College of Surgeons in London, in order to which, *complete* courses of anatomy and surgery are required. Of your memorialists, some have become students in arts, for the purpose of obtaining here a complete medical education, and a medical degree; and all have enrolled themselves as pupils of the University, in order to acquire that extended and useful course of medical education, which the present state of medical science, and the high reputation of the professor of anatomy and surgery, led them to expect. Your memorialists further beg leave to say, that they and their friends have made various arrangements, which cannot now be altered without great inconvenience, and some pecuniary loss to themselves, in the expectation of attending the lectures on surgery at three o'clock; and they do not wish, for this reason, to attend any other lectures at that hour. They therefore most respectfully beg that the board will revoke their recent order, and permit them to attend the lectures on surgery, from which they have every reason to expect the most useful information, and certificates of which are, to many of them, indispensable towards their attainment of a medical degree.

From Dr. Macartney, to Dr. Phipps.

Sir,—The board not having signified their pleasure respecting the memorials of the pupils, and the door of the anatomy house having been locked Saturday, and to-day, it may be concluded, that it is intended to persist in the exclusion of the pupils from the surgical lectures at three o'clock. Those who purpose graduating here, are very anxious to know whether the board will grant the licet for examination, without my certificate for surgery; or if they will accept a certificate for the *imperfect instruction* on *both* subjects, which can be given at *one o'clock.* The hour of twelve, (the only one unoccupied by other professors,) would be totally impracticable, as some time is necessary to make arrangements for each of the subjects I teach; and would also be objectionable, as interfering with tutors' lectures, and those on divinity. Some gentlemen are attending me this year, who wish to qualify for both the clerical and medical professions, on account of the present uncertainty of provision in the church. I must beg that the board will condescend to give me an answer on these points, as involving so seriously the interests of the students.—I am, sir,

Your obedient servant,
JAMES MACARTNEY.

Dec. 8, 1835.

From Dr. Phipps, to Dr. Macartney.

Sir,—In replying to your letter of the

8th of Dec. inst., I am directed by the board of Trinity College to communicate, that they will accept your certificate for the attendance of students on your course of lectures, given at *one o'clock, in anatomy and surgery*.—I am, sir,

Your very obedient servant,
ROBERT PHIPPS, Registrar.

Trinity College, Dec. 15, 1835.

In consequence of these proceedings, we understand that Dr. Macartney, in order to accommodate his pupils as far as possible, has determined to give, *during the present season*, five lectures in the week, on anatomy, at one o'clock, and one lecture on surgery in the week; but as the latter arrangement must be deemed insufficient in every institution except Dublin College, he has returned their money to those students who are preparing for the surgical diploma, or for Edinburgh degrees.

Such are the strange things which may sometimes be done by Boards entrusted with the management of medical education. May it not be a type of any metropolitan Board to be hereafter appointed in this part of the empire! But it can hardly be; for the circumstances of the Irish medical school are peculiar. The whole concern is incongruous, being partly belonging to the University and partly to the College of Physicians in Dublin; but at all events the Professorship in question is at the disposal of a non-medical body, who have never been very distinguished for their cordial or liberal bearing to an establishment to which they are far more indebted than they seem to have any disposition to confess.

On the present occasion, the College Board, we think, can scarcely be congratulated save for the original and comic part they have played in the transaction. There has never, we believe, in the whole history of schools and colleges, been a previous instance of the *masters barring out the scholars*, however usual the reverse proceeding has been; yet here we have it performed by the grave seniors of Trinity College, Dublin. And to make the whole affair more ludicrous, the comedy was enacted, too, just before the Christmas holidays; the doors being fast barred even during some part of the vacation!

The consequences, however, of this foolery, may prove more serious than the worthy Board imagine. They have curtailed the usefulness of their Professor; and the lectures on anatomy and surgery in the University of Dublin are now, so far as graduation in any other locality than Dublin is concerned, profitless. This we have thought should be made known to the public; and especially to those students who might, without such warning, repair to Dublin, intending to obtain an education which should enable them to graduate elsewhere. They now know the sort of education they have to expect in what can be, only in Ireland, called the *complete* School of Physic.

ON THE

TREATMENT OF WHITE SWELLINGS.

By M. LISFRANC.

Reciprocal Connexion between White Swellings and Internal Visceral Disease—Effects of Motion—Proper Position—Method of Measuring the Joint—Question of Amputation—Diet—Treatment of the Disease in the Inflammatory Stage—Mercury—Barytes—Bleeding—Baths—Treatment of the Chronic Stage—Leeching—Compression.

General Remarks.

WHENEVER we are consulted by a patient affected with a white swelling, we ought to examine with great care into the state of the thoracic and abdominal viscera, for it is, unfortunately, but too common to find some internal organic disease coexistent with the external tumor. It is unnecessary for me to point out the manner of conducting this investigation, for this would be to describe the various maladies alluded to.

It may perhaps be said, that a white swelling ought to be treated in the same manner, whatever disease may exist elsewhere; but I do not at all coincide in this opinion, because, under such circumstances, when we combat the progress of a white swelling, and attempt to cure it, if we are so unfortunate as to succeed in doing so, the internal disease makes such progress in consequence, as inevitably to prove speedily fatal. On the contrary, in such cases I hesitate not to apply rubefacients, blisters, and other means, to irritate the external swelling, and to prevent it from receding, by which the progress of the visceral disease is retarded. I would add, besides, that even where we have care-

fully examined the internal organs, without finding any thing amiss, disease may yet exist in a latent state, and become apparent just in proportion as the white swelling advances towards a cure; as may be verified by the autopsy when death takes place.

Such cases may be compared to those of amputations performed in those whom we have not suspected of having any internal disease, but in whom, during the fever which follows the operation, the first symptoms of the previously latent affection shew themselves, and rapidly proceed to a fatal termination. There certainly exists between the large joints and the abdominal viscera a degree of sympathy which has not hitherto been sufficiently estimated. The pain and weakness experienced in the joints at the commencement of fevers farther illustrate these sympathies.

Many of you may have observed, a short time ago, a young man (No. 17, St. Louis) affected with a white swelling and phthisis pulmonalis; this patient exhibited, in the progress of these two diseases, some very remarkable circumstances. We saw that in proportion as the phthisis advanced, the white swelling, which at first was very large and painful, gradually diminished and became indolent, so that before death the joint had really regained its natural size. Nothing, in fact, is more evident than such sympathies, and probably they act an important part in the benefit which we derive by producing salivation in cases of white swelling. When we have to deal with articular disease complicated in this manner, we must limit our exertions to the means best calculated to arrest their progress, and direct our main efforts against the internal complaint; or if this be in its nature incurable, then we must be satisfied with palliatives as applied to both. By acting differently we should rather augment the more formidable internal affection; and this point in the treatment of white swellings is extremely important, though not sufficiently attended to.

Unless white swellings be in a perfectly chronic condition, the limb must be kept in a state of absolute repose; and no exception is to be made to this rule, because if the patient use the joint, he incurs the risk of rendering the disease acute. But it must be kept in mind, at the same time, that absolute rest exposes him to the danger of having ankylosis, or, at least, a false ankylosis: it is necessary, therefore, that either the practitioner or the patient communicate a certain degree of gentle and regulated motion to the part every day. There are some rules to be laid down with respect to this also. If the movements give very little or no pain, they may be continued; but if, on the contrary, they excite uneasiness, and more particularly if this remains some time after the movements have been discontinued, they must be altogether abandoned, as it is better to run the risk of ankylosis rather than of acute inflammation, which might hurry on the disease so as to render amputation unavoidable.

Another point, in itself very simple, though not sufficiently attended to in practice, is the position which it is most advantageous to give the limb. This is often neglected; and among the patients who come to this hospital many have the leg bent upon the thigh, so that when the original disease is cured, we have still many months' work in contending against the ankylosis; nor are we always successful even then. If the swelling be in the knee, of course the limb must be kept extended; nor, indeed, is this position more painful than any other; but were it in a slight degree otherwise, still it were better to bear this than have the limb ankylosed in a bent position. I do not think it requisite to point out in detail the position fitted to each member, because this must be obvious from a consideration of its use.

Abscesses often form round white swellings: they must be opened as speedily as possible, because they would otherwise become extensive, burrowing beneath the skin, and forming innumerable fistulæ. When the parietes of these become inflamed, the suppuration is so copious as to endanger the life of the patient.

It is useful, during the treatment, to ascertain the change of volume which the parts may undergo. To accomplish this, three lines may be made at different points around the joint with the nitrate of silver, so as to blacken the skin. Each of these becomes a mark, at which the limb is to be accurately measured; and by repeating the measurement about once a week, the changes of size are readily ascertained. This guides the treatment, and has a moral effect upon the patients; indeed, they will never otherwise believe that the swelling does diminish, owing to the extreme slowness with which any diminution takes place. We ought never, therefore, to omit an expedient which assists the surgeon, and encourages the patient under the long treatment to which he is unavoidably subjected.

When a white swelling cannot be cured, and when we have once thoroughly made up our minds as to this, is it advisable—as some surgeons recommend—to delay the amputation as long as possible, in

order that the patient may become weaker, and the chances of success be increased? This precept is a most unhappy one, and has caused a host of failures. Beware of following it; for while you are procrastinating, the alimentary canal is apt to become implicated, diarrhœa supervenes, ulcerations take place in the bowel, and the case is then lost. If your patient be too plethoric, it is easy to relieve him by blood-letting.

In general too little importance is attached to regimen in the treatment of chronic surgical cases; patients are allowed to continue their accustomed diet, by which the disease is often rendered more obstinate. I have seen many cases which resisted the most approved treatment, and which have begun to yield the moment that the diet was changed. The quantity of food must be diminished in the first instance by one-fourth, and then by one-third, and even, if possible, by one-half; unless, indeed, there be a scrofulous diathesis, or the swelling be in a state entirely chronic. I shall not enter into details on this part of the subject (merely pointing out to you its great importance), but shall proceed to speak of white swellings with *sub inflammation*, and those without this condition.

Treatment of the Acute Stage.

Mercury may be employed, so as to produce salivation; but this sometimes disturbs the stomach before the desired effect is produced, and many persons are unwilling to submit to the treatment, as it is unpleasant, and produces emaciation. Another remedy is presented by the muriate of barytes, particularly in scrofulous cases; but the disease is not always connected with scrofula, and it either fails, or succeeds but partially. Upon the whole the results obtained from both these remedies are often unsatisfactory; when this is the case, recourse must be had to blood-letting.

If the patient be very robust, and the inflammation very acute, two or three palets of blood may be taken from the arm; and this may be repeated next day, or next but one, according to the effects which have been produced. It is of importance to remove the plethoric state, and to empty the vascular system. If after these general depletions the inflammation still persist, recourse must be had to local bleeding; but this must not be pushed too far, because, first you have to deal with patients labouring under a chronic disease, by which they are often already much weakened; and secondly, because the complaint is of long standing, and has acquired, if I may so speak, "a kind of right to the joint," producing in it a change of texture, which cannot return to a healthy state except by slow degrees. Accordingly, when you employ leeches to the extent of fifteen, twenty, thirty, or forty, according to the constitution of the individual, you must not employ them several days successively, because this would reduce your patient too much. It is because these abstractions of blood have been carried too far that some have found them injurious, and looked upon them as inapplicable. It is also necessary to observe how the patient bears depletion. One person scarcely feels any effect from a bleeding, while another becomes feeble and blanched. We must therefore examine the pulse, notice the complexion, &c., and always keep in mind that bleeding ought rarely to be practised oftener than once in six or eight days. Again, if they have already brought the swelling into a chronic state, depletions must be used no longer with the same freedom, or merely as an antiphlogistic means; this would be to weaken your patient to no purpose whatever.

To the abstraction of blood you may join various other antiphlogistics, in the acute stage. If the seat of the disease admits, you may have recourse to topical baths; but take great care that the temperature of these be not either too high or too low; it ought to be such that the patient experiences no sensation either of heat or cold on placing the joint in the bath. Simple emollient fomentations are also advised, but I scarcely approve of them in the acute stage, and think they are only proper when this has passed away. Emollient cataplasms, either simple or with the addition of opium, ought to be applied twice a day. For the most part, the acute stage passes into the chronic in about three weeks, under the use of the above remedies; but sometimes the inflammation lasts much longer than this. I have seen it continue three, four, and even six months; and, indeed, in one case it lasted nine months; after which, the chronic stage which followed likewise endured nine months; when the patient recovered. In such a case, where the inflammation is obstinate, if salivation, or the muriate of barytes cannot be used, or have been so with success, what ought we to do? Are we to apply leeches in large numbers? Certainly not; we should thus reduce our patient too much. We must proceed more gently; applying leeches but only once in each fortnight or three weeks, and choosing for this those times when the inflammation seems to be undergoing an exacerbation. By acting in this manner we frequently contend with equal weapons against this rebellious disease, and we at least succeed in arresting the proper course of the malady. After

a time, in short—either in consequence of the health improving or the disease of the joint having expended its force—the inflammation passes into a chronic state. In such cases the important point is, not to weaken the patient by carrying the antiphlogistic plan too far.

Treatment in the Chronic Stage.

I now proceed to speak of the treatment to be pursued in the chronic stage of white swelling—that is to say, when it is characterized by a complete or almost complete absence of pain and increased heat. It is necessary, in the first place, to establish a principle which is essential to the treatment of white swellings in general, and to this form of the disease in particular. When the acute stage has passed away, if we immediately have recourse to excitants and discutients, even when the chronic condition has existed but a few days, the acute state, which is scarcely overcome, is very apt to return under the use of such remedies. Thus, suppose you observe to-day that a white swelling has become chronic; if to-morrow, or the day after, you apply leeches in reduced number, or pressure, or blisters, or moxa, or douches, you will often see the acute state brought back, because the part has been too much excited by these remedies. It is necessary to wait at least eight days, so as to afford time for the chronic state to be confirmed, before you combat it. I insist upon this the more because it is not sufficiently impressed upon the minds of practitioners.

It is of no great importance in what order we consider the various methods to be employed in chronic white swellings: however, I shall speak first of those which I regard as most efficacious,—most generally applicable, and always to be tried before those more energetic expedients which I shall recount in the last place. The first of these methods consists in the application of leeches in small number at a time.

Mode of using Leeches.

The number of leeches, under such circumstances, may vary from three to six, or at most eight, and this only in robust individuals: it is an excitant means, a true resolvent; and in support of this opinion I shall mention some illustrative facts. In violent inflammation, on an acute attack of peritonitis, for example, we are so much afraid of causing congestion of the part by leeches, that we premise their use by venesection; after which they are applied, but in very larger number. The application of leeches on the upper extremities, as well as small bleedings occasionally repeated, often give rise to symptoms of congestion in the thoracic viscera. Leeches applied in small number, more frequently cause erysipelas than when applied more copiously. If we wish to bring on the menses, we do not apply thirty or forty leeches to the thighs, but limit the application to six or eight; and we should farther endeavour to promote the object by arresting the bleeding from the leech-bites soon after they had dropped off. Barthez held that leeches ought not to be applied till an inflammation was on the decline; and this principle is easily explained, when we call to mind, that, in his time, leeches never were employed in large numbers at a time, and at the onset of an inflammation it were better not to apply leeches at all than to apply but a few.

In patients who have a tendency to apoplexy, when a white swelling or any other tumefaction of analogous character is situated on the upper part of the body, we must abstain from the use of leeches in small number. I have more than once seen cases in which such swellings affecting the elbow, or even the wrist, have had leeches used in this manner, with the result of producing all the indications of apoplexy. You will find in the thesis of M. Costen, how a few leeches, applied to a schirrous breast, have caused congestion of the lungs, or disturbance about the heart; and we ought therefore to abstain from this method wherever there is disease of these organs. It is also clear that the menstrual flux ought to be attended to, and respect had to the six or eight days which precede it; for, by applying leeches at such time to the lower extremities, you will make the period anticipate, and probably render the discharge more abundant; while, by applying the leeches to the upper extremities, you may suspend or retard menstruation. These facts are important, but unluckily there is nothing to be found on the subject in books.

Now, when you apply leeches in small number to white swellings, there may be, 1st, no perceptible effect; you apply four or six leeches to-day, and to-morrow you measure the swelling—you examine it carefully, and find no change;—2dly, there may be an increase of size, to the extent of one, two, or three lines, with a little œdema and a little softening of the tumor. This effect, which astonishes and frightens the patient when it has not been anticipated, is in general very favourable. Absorption soon commences, and in twenty-four or forty-eight hours more, the swelling is found not only to have returned to its former size, but even to have diminished some lines. 3dly, Without œdema or any increase of volume, you determine by the touch that there is a

softening of the tissues; and this will be followed, in the course of two or three days, by a diminution in the tumor: or the excitement may have been greater than we had supposed, in the preceding cases, and then a slight erysipelas comes on. This also is a good omen; for I have never, or almost never, seen an instance in which this was not followed by a marked improvement in the swelling. This superficial inflammation disappears in a few days, and then the tumor, which had at first increased, begins sensibly to diminish. Lastly, common erysipelas may come on: this constitutes a complication of the disease which must not be left to itself, for the inflammation may extend to the subjacent textures, and you know what mischief this may do in textures already so much diseased. Leeches must then be applied in great numbers, and generally succeed in arresting the erysipelas; in which case, the same advantageous effects result as from the milder degree of the disease above alluded to.

When are we to renew again the application of but a few leeches, on the former principle? The period must necessarily vary according to the effect which is produced. When they have effected no visible change, I wait five or six days; but if any effect has followed, I then rest on my oars till this has disappeared for two or three days. Leeches thus applied do not weaken the patient, and may therefore be used many times; but at length they lose their effect, the constitution becomes habituated to them just as to opium, and we must then abandon them for a time for other remedies; after which we may return to them again.

But if this method may be employed alone, it is also capable of being combined with other means. Thus, when the leeching has produced softening of the swelling, but this is not followed by a diminution of its volume, we may then have recourse to compression. After a time the leeches may again be used, and, in fact, the two methods may be alternated.

Of Compression.—The end proposed by this means is double: first, that of lesseni the arterial circulation in the tumor, so as to diminish its irritation, and secondly, that of promoting absorption.

What proves that pressure produces the former effect is this,—that if it be only established on the tumor itself,—if the cones of agaric do not extend at least an inch beyond its circumference, the compression succeeds less fully, less frequently, and less rapidly. Is it not universally known that pressure causes the part to which it is applied to waste, or at least arrests their growth? Is it not thus that a ligature round a tree prevents the growth where it is applied? Is it not well known that too tight garters, especially in women, lessen the volume of the limb, and after a time lead to deformity? Experience proves that in acute inflammations, pressure often renders them more aggravated, while in indolent swellings it often brings back the acute state, so as to require to be discontinued. As we regulate the dose of opium, of antimony, and other medicines, why should we not also measure our dose of pressure? Are swellings always equally hard?—are they always equally sensible? Certainly not: and accordingly we must carefully regulate the degree of pressure, so that it be proportioned to the state of the parts, the duration of the disease, and various other circumstances.

First dose.—Slight pressure, produced simply by circular bandages.

Second dose.—Pressure a little increased by means of agaric cones and bandages, as before.

Third dose.—More energetic pressure, with graduated compresses, and circular bandages.

Fourth dose.—Still stronger pressure, made by means of some hard flat substance, or pieces of money wrapt in linen, and circular bandages. Pressure employed in this way succeeds extremely well on the hand, and indolent swellings which remain after fractures and luxations of the wrist, and which resist in general the other *doses* of pressure. But it is evident that this cannot be applicable in white swellings, or any other tumor which has but recently become chronic.

Fifth dose.—This consists in kneading (*malaxation*). We had lately a patient here who had an induration at the outer part of the knee, which had resisted the other methods of compression, and only yielded to this.

We must always be ready to supend the compression when it passes the degree and effect intended, and its employment must be subjected to all the rules which ought to regulate the practitioner in the use of discutients. Thus, if heat and pain reappear, it is to be left off: if the effects just mentioned last more than twenty-four hours, they are to be combatted by antiphlogistics, and we only return to compression when these effects have entirely disappeared. Some details may be necessary as to the application of the second dose of pressure. The agaric ought to be soft, thick, and good; for if it be hard or thin, and but little elastic, the pressure would necessarily be greater, and become equivalent to a higher dose. The agaric is to be cut into round portions of unequal size, so that when placed one above another, they may form truncated cones of an inch or an inch and a half in height:

the base of the cone ought to be sufficiently large to embrace the tumor, and extend an inch beyond its circumference. In most swellings of this kind, several such cones are required to effect a regulated pressure over the whole extent.

What follows with regard to pressure, applies to other tumors as well as to white swellings. Sometimes the tumors are moveable, and roll so as to escape from the action of a single cone of agaric: nothing is more common in glandular swellings. In order to fix such a tumor, several small cones are to be placed round the circumference of the tumor, and one large one upon it. In the axilla, for example, in order to prevent enlarged lymphatic glands from escaping, a cone must be placed above them, so as to force them downwards, and keep them within the action of the larger cone, which is then to be placed right over them.

The pressure ought not to be kept up during three or four successive days, because the circular bandages get relaxed, and the pressure thus becomes unequal; but the apparatus ought to be resumed once in each twenty-four hours, and the patient allowed to remain about a quarter of an hour without it.

When pressure is applied to the chest, it must be made lightly during the first few days, lest the respiration be too much impeded. M. Recamier has contrived a kind of corset expressly for this purpose.

As to the rest, compression may be employed at the same time as other means calculated to disperse the tumor, such, for example, as frictions with the hydriodate of potass; it ought also to be alternated occasionally with the application of leeches in small numbers. When the swelling is quite gone, it is, nevertheless, prudent to continue the pressure for some weeks, or even months, if the case be one of schirrus, as we thus frequently prevent the recurrence of the disease.

It has been said that pressure would cure cancer in a state of ulceration. I do not think so; and, in truth, if you consult the cases which have been published, you will perceive that pressure has not been employed alone. The centre of the tumor has first been destroyed by means of the knife, or caustic potass, after which pressure has been employed, with a view of dispersing the rest of the disease. I believe that in such cases, where they have proved successful, the cancer has been destroyed by the first part of the process, and that the surrounding induration has been no more than that hardness which we meet with around such tumors, but which has not yet taken on the cancerous action. This is a subject on which I have elsewhere advanced opinions, which appear, to me at least, to be of great importance.

In tumors regarded as cancerous, as well as in all others, I reject the plan of compression — 1st, when the symptoms show a certain degree of acute inflammation, either in the tumor itself or in the surrounding textures; 2dly, when the tumor, although not very large, is hard, unequal, and knotted, adherent to the skin, and particularly when the skin itself is the seat of suspicious-looking ulceration (unless removal of the really schirrous part be premised); 3dly, when the tumor, whatever be its size, presents some points which are indurated, and others which are soft; when these softened portions afford that kind of spurious fluctuation often mistaken for genuine fluctuation, which shows a pultaceous disorganization of the tumor.

It is because these cases have not been distinguished,—it is because the necessary indications have not been attended to,—that compression has been so often r-jected as a dangerous precedent. It was this, without doubt, which led M. Dupuytren to describe it as rendering cancers more adherent, accelerating their progress, and producing ulceration. I have, however, to congratulate myself on having many times succeeded in saving the mammæ, in women in the better ranks of society, after other surgeons had condemned them to amputation, as the only possible means which remained; and this success is the more gratifying, inasmuch as many of these cases are now of several years' standing, and appear to be, to me, radically cured.

When the tumor, then, is not already far advanced, we may hope to be able to cure it; and still more frequently do we succeed in diminishing the swelling, and rendering any operation more simple when at length it becomes necessary. But if a tumor, after having been improved by compression, or without such change, becomes again altogether stationary—if no impression be made upon it by any other discutient means, we must be prepared to see, as I have often done, a sudden and rapid cancerous degeneration supervene. Under such circumstances do not think of pressure, but operate without loss of time. I think, in short, that compression, well regulated, and applied in cases properly selected, may succeed, and do wonders. Patients, women particularly, will always submit to it more readily than to an operation. But if the compression should fail, or even produce any inconvenience, we then have the knife left when we are satisfied that it alone will do.

I shall conclude these remarks by re-

commending you to attend to the medical treatment as well as to the surgical, for you will thus certainly have more success. The treatment by pressure must therefore be aided by such internal remedies as the case may appear to require.

ST. THOMAS'S HOSPITAL.

Mr. Travers on various Causes of Stoppage of Urine—Obstructed Ureters—Burst Bladder —Perforated Bladder—Retention from Paralysis.

There may be many different causes of an obstruction to the passage of the urine. It might happen to you, as it has to me, to be called to a patient whose belly is much distended, who is suffering great pain, and into whose bladder you pass a full-sized catheter without any difficulty, and not a drop of urine escapes. However, you feel assured that you have made no mistake; because that peculiar sensation of free motion of the extremity of the catheter with which every man is familiar who is accustomed to use it, satisfies you that the instrument is in the bladder. But no relief follows; and in the course of a few hours, at all events in a very few days, the patient dies. I was called to such a case a few miles out of town. It occurred in a corpulent gentleman, in whom, after death, I found that both ureters were filled with calculi, one at the pelvic, and the other at the vesical extremity; so that not a drop of water found its way from the kidneys to the bladder. The effect of this was to produce an absorption of urine, and arrest the secretion of the gland. In another case which was under my care many years ago, the same thing happened, only that it was more gradual and complicated. First of all there was great dysuria, and then what appeared to be suppression of the secretion, ischuria renalis: we found, on one side, a very diseased kidney, and a rose-bud carcinomatous fungus shutting up the corresponding ureter at its termination in the bladder; and the other, by which the urine was chiefly secreted, had a calculus impacted in its duct; so that here again it was the ureter, and not the urethra, that was in fault, though the case was strictly one of retention of urine. I need not say that in such a case one can do no good. Some time ago a body was opened in this hospital, in which there was an enormous sac, like a secondary bladder, formed out of the canal of the ureter, which had become obstructed and actually doubled upon itself. My son conducted the examination; it occurred in a patient under the care of Dr. Williams.

Another case I may mention by the way. You are called to a patient suffering great pain, and sudden inability to void his urine, after a fall or blow upon the belly. The catheter passing easily into the bladder, urine flows in small quantity, but suddenly stops.

I was called to a stout heavy man, in middle life, who having fallen over a bench upon his belly, in a public-house scuffle, was seized soon afterwards with acute pain, and found he was unable to relieve his bladder. No sooner was the catheter introduced, and about a quarter of a pint of fluid evacuated, than the stream stopped suddenly, and the bladder was collapsed. In about thirty-six hours he died in great agony. You may anticipate what was found; it was a case of burst bladder, the contents having escaped through a rent in that viscus into the abdominal cavity, the bladder having been at the time of the accident in a state of distention.

A surgeon of eminence told me of a case in which a young practitioner having made a good deal of effort to pass a stricture, thinking that he had at length overcome the difficulty, left the patient, who expressed the sensation of making water. Shortly afterwards he was summoned, and found the man writhing with pain, having passed no water, and his belly swollen: in a few hours he died. The surgeon had actually contrived to drive an instrument of some sort through the coats of the bladder into the peritoneal cavity. Without great ignorance and great temerity, this could not have happened; but so it was.

I doubt if, from simple retention, a bladder would ever be found to burst, as the uterus, for example, is sometimes known to do from its own action, in endeavouring to expel its contents, because the action by which the bladder is emptied depends in a greater degree on the surrounding muscles. It has no great muscular power of its own, as is indeed proved by its incapacity to act at all on its contents, after a certain extent of dilatation has taken place. Extreme dilatation has the effect of paralyzing the organ; and, therefore, we every now and then meet with a case of complete retention of urine from over-distention of the bladder. You know that in accidents of every description, from shock of the nervous system, we are very often obliged to resort to the catheter, sometimes for days, but more frequently once or twice only. But it will often happen, without a practitioner adverting to it, that a man will, for a very long time, labour under a partial retention

of urine; and I have known this inattention, from whatever cause, carried to a fatal extent.

You will be surprised to hear that an old gentleman, whom I was once called to the country to see, had passed no water, unless perhaps a few drops now and then, for nine days; and you will be much more surprised when I tell you, that his symptoms were even referred to other causes, and that I passed a catheter into his bladder with the most perfect ease. There was literally no obstruction worth noticing to the passage of the instrument; but it was some time before any fluid would pass, and when it did, it was like any thing but urine. It was purulent, sanious, and horribly fetid; but either the retention had been overlooked or concealed; for, strange to say, it had not been removed, although, in point of fact, the operation presented no difficulty. It is a lesson, to show that every practitioner should make himself familiarly acquainted with the manual, the little tactic of the catheter, as well as with the phenomena of retention; for it is as much from a want of confidence in some cases, as from over confidence in others, and both due to ignorance, that such mischiefs arise. This old man's bladder presented an enlarged prostate, acting as a valve, and was found to have undergone, from excessive distention, a complete slough of the mucous coat, which was detached, and floating in the form of a flocculus. In such a case you can only get the urine to flow through the catheter by actual pressure on the over-distended bladder.

* * * * * * *

Use of the Catheter—Precautions in forcing a Stricture—False Passages.

If a stricture is causing so much retention as that it becomes justifiable, nay, a duty, to employ force, there are certain precautions by which a man whose hand is practised will prevent the accidents that would otherwise be likely to befal the patient. The most important of these is the guarding of the perineum, that is, the membranous portion of the urethra, by planting the forefinger and the finger next it beneath the bulb and behind the pubes, so as to support the parietes of the canal —always taking care to preserve the median line, for all wanderings from this are dangerous; and keeping the point of the catheter as accurately as possible in contact with the upper or anterior surface of the urethra as it glides along. If you do this, and at the same time support the parietes of the canal, by placing the fingers in the perinæum, one on either side, you are in little danger of doing mischief, especially if you do not use an inconsiderately long or curved instrument.

The old surgeons, especially the French, used to employ a manœuvre, which they called the *tour de maitre*, in passing the catheter. They entered it with the convex side uppermost, and having passed it on until they had reached the part at which the canal quits the bulb and passes through the triangular ligament into the pelvis, they revolved the instrument upon its point. In that evolution, if dexterously performed, it often happens that the instrument will slip, as it were, into the bladder. However, this is a manœuvre that one cannot hold out to general imitation, on any reasonable ground of preference to a simpler method. Every man has a way of his own, but the simplest method is generally the safest. Having carried the point of the instrument to the pelvic or fixed portion of the canal, the remaining manipulation consists only in such a depression of the handle as shall tilt the point of the instrument into the bladder. Amply sufficient force can be thus applied without any onward pressure. The recumbent is preferable to the standing posture, as it takes off muscular resistance and fixes the pelvis. A middle-sized catheter should be tried in preference to a small one. You will readily believe that much depends on habit; and as it is an operation to which the surgeon is often called on urgent occasions, on the result of which sometimes hangs the life of the patient, it is worth his while to make himself throughly versed in it, and to omit no opportunity of practising it.

Except it is a case of absolute retention of urine, you are not justified in using an extraordinary degree of force. But you may be called to a case in which spasm having supervened upon a bad permanent stricture, from the patient having drank too much at a revelling party the preceding night, or delayed too long from inebriety, sleep, or even forgetfulness, to unload his bladder; he is unable to pass a drop of water, and suffering great agony from ineffectual efforts for his own relief. In such a crisis, the state of bad permanent stricture having previously existed, it is loss of time to employ the remedies applicable to the pure spasm; though I know no objection to giving fifty drops of laudanum, and repeating the dose in ten minutes if called for, or to douching the pubes with cold water. But as the state of parts is not propitious to the employment of instruments, though force will be necessary, it should be tempered with caution.

If the perineum be of ordinary dimensions without enlargement, or any great enlargement, of the prostate, you may

materially help yourself by passing a finger into the rectum; the instrument being in the urethra, at the seat of stricture, tilting the point when you feel it bearing on the finger through the wall of the rectum, will very often throw it into the bladder. In some bad cases, after working for a length of time, I have succeeded by that plan.

With regard to the *sonde conique* used by some of the French surgeons, although I once employed it with perfect success in an inveterate stricture in this house, where caustic had failed, yet the use of this and of the stiletted or lancetted instruments I think better avoided in the treatment of stricture, because, in any hands whatever, a great additional risk is run of doing mischief.

Many cases are made worse by treatment; and it is probably not too much to say that more suffer from want of skill, imprudent force, or abuse of the remedy, whether the common or the caustic bougie, where the patients pass through many hands, as those of the humbler class, than even from neglect or intemperance on their part. One great source of these mischiefs is a foolish feeling of baffled pride in the young surgeon if unable to reach the bladder, even though the extension be not urgent. This is most absurd, and greatly to be deprecated. It is by steady repetition of the attempt that the severe stricture is most safely and surely overcome. Absolute retention is the only apology for the employment of force with every precaution. There are, in the collection of this hospital, numerous examples of false passage. One shows a cylindrical perforation of the triangular fold at the base of the prostate, the *trigon vesical*, and another the prostate itself bored through by an instrument in its way to the bladder. Some show nests of abscesses in the bulb of the urethra, and in the prostate, with thickened and variously diseased conditions of the prostatic urethra and bladder. In others we may trace so confirmed a state of false passage, that after quitting the canal for some lines, the instrument regains it before entering the bladder. This may happen anterior to the bulb of the urethra, or in the bulb, or in the membranous portion, or beside the verumontanum. Further, the instrument may pass between the rectum and bladder, or even penetrate the rectum, or between the abdominal muscles and peritonæum; and I have seen urinous abscesses thus formed in the tunica vaginalis reflexa, and in the posterior peritonæal reflection communicating with the abdominal cavity.—*St. Thomas's Hospital Reports*, No. 2.

SMALL-POX AND VACCINATION HOSPITAL, ST. PANCRAS.

Dr. Gregory's Report, addressed to the Governors.

During the ninety years which have elapsed since the foundation of the Small-Pox Hospital, there never, perhaps, was a year in which its advantages to the public have been more conspicuous than in that now passed. 401 persons have been treated within its walls, and so many centres of infection have been removed from this vast metropolis. Of that number, 89 have died, and 312 have been restored to their families and friends.

4140 persons have been vaccinated at the hospital in 1835; and 1767 persons, chiefly medical practitioners, have been supplied with vaccine lymph, for the use of the public, at home and abroad. It is no exaggerated statement to say, that nearly 7000 persons have participated in the benefits of this charity during the course of the past year. It will readily be conceded, that such ample opportunities must have furnished to your physician much useful information. To some points in which the public are interested, no less than the members of the medical profession, he n w proceeds briefly to direct the notice of the Governors.

The records of the hospital, during the past year, sufficiently attest that the hopes once entertained of banishing the small-pox from the earth, are utterly visionary and groundless.

Thirty-six years have elapsed since the general diffusion of vaccination throughout this country; yet small-pox still exists, and, by the bills of mortality, may be shewn to have proved fatal to 863 persons in London alone during the last year. In various parts of the country it has shewn itself during the same period. Nor do other quarters of the globe enjoy an exemption from the disease denied to us. On the continents both of Europe and Asia, small-pox has recently occasioned considerable devastations, and attracted a large share of public attention. Without inquiring how much of this depends upon the defects, and how much upon the neglect, of vaccination, enough appears upon the face of the statement to shew, that an hospital, exclusively devoted to the cure and prevention of small-pox, is imperatively required in such a metropolis as London; and that the patronage of the public cannot be withdrawn from it on any plea of its diminished efficiency.

The experience of the past year shews, secondly, that the confidence of the public

in and about London, in the protective power of vaccination, has in no degree diminished. The numbers vaccinated at the hospital in 1835, *exceed that of any former year*. In no instance has any doubt or distrust been manifested by the parents of the children; and as small-pox infection has been rife in all parts of London throughout the whole of 1835, their confidence can have resulted only from personal experience of the security which vaccination holds out.

The records of the hospital shew further, that this security, though so remarkable in the early periods of life, is not so complete and permanent in after-life as might be wished, and as at one time might reasonably have been anticipated. One hundred and forty-four persons, labouring under small-pox, have been admitted during the year, who in early life had been vaccinated. All of them, with few exceptions, were adults; an interval, varying from ten to thirty years, having elapsed since the date of their vaccination. Two thirds of this number had small-pox in a mild form, wholly devoid of danger. The remaining third were less fortunate, having passed through the disease with greater or less degrees of severity. Still the mortality in this class of patients was very small, hardly amounting to five in a hundred, while the unvaccinated perished in the proportion of thirty-three in a hundred.

These considerations tend to shew, that vaccination is still entitled to the highest praise as a means of diminishing both the quantity and the severity of small-pox—that it is an object of national importance to encourage and foster it—and, lastly, that the attention of medical men cannot be too strongly called to the necessity of carefully selecting the lymph they employ, and accurately investigating the several causes on which its diminished efficiency in the more advanced periods of life may depend.

George Gregory, M.D.
Physician of the Small Pox and Vaccination Hospital, King's Cross.

31, Weymouth-Street,
Feb. 4, 1836.

REMUNERATION TO MEDICAL WITNESSES.

PETITION TO PARLIAMENT.

To the Editor of the Medical Gazette.

Sir,

I enclose you a copy of the petition to the House of Commons prepared at a meeting of the Committee of the Bucks Medical Association, lately held at Aylesbury. It is now in course of signature, and will shortly be ready for presentation. The support of its prayer will be earnestly requested of the county and borough members.—I have the honour to be, sir,

Your obedient servant,

Robert Ceely,
Hon. Sec.

Aylesbury, Feb. 15, 1836.

To the Honourable the Commons of Great Britain and Ireland, in Parliament assembled.

The Petition of the undersigned medical practitioners, in and near the county of Bucks, humbly sheweth,

That your petitioners have at all times been ready and willing to further the ends of justice in their attendance on coroners' inquests.

That the duties of medical practitioners on such occasions are highly important and very responsible, and require, for the due performance thereof, extensive knowledge (acquired at considerable expense) and the sacrifice of much time and labour, often at a distance of many miles from their habitations.

That for the satisfaction of the jury, it is not unfrequently required to pursue a series of delicate, tedious, and intricate chemical investigations.

That still more frequently it is necessary to institute post-mortem examinations with care and judgment, and oftentimes at considerable risk of health and life.

That your petitioners humbly submit, that a coroner's inquest, without efficient medical evidence, can be but an empty form, and consequently a source of useless expense.

That your petitioners, in common with the medical profession, consider it a great hardship that the law does not provide any remuneration for such important services.

That your petitioners respectfully, but earnestly, beseech your Honourable House to afford them substantial relief from so manifest an injustice, by the enactment of such a measure as your Honourable House, in its wisdom, shall think fit; and your petitioners will ever pray, &c.

REMARKS

ON

RURICOLA'S SCALE OF REMUNERATION FOR PAROCHIAL SURGEONS.

To the Editor of the Medical Gazette.

Sir,

The letter of your correspondent, "Ruricola," in a late No. of the Gazette *,

* See Medical Gazette, Jan. 16, 1836.

has afforded me much satisfaction, and I doubt not but that feeling is general throughout the profession. Sincerely do I hope that the principle which he has suggested may be adopted by the different Boards of Guardians throughout the kingdom. Approving, however, as I do, of the principle, there is one suggestion which I am anxious to make respecting the details of the plan, without which, I think, the scale of remuneration will prove too low. I know, from experience, that under the new Poor-law, a more than average share of chronic cases of illness falls to the lot of the parochial surgeon; some of those cases being of many years' standing. I would therefore recommend, that when a case continued on the list more than three months, the order should be renewed; and thus a case continuing for a year would be paid for as four cases. If this is not done, the medical attendant on very small parishes, where the cases do not average more than four or five a year, will, if one or two of these should prove tedious, be very inadequately requited for his services.

I have calculated the attendance on six parishes in the Eastry Union for the last six months, according to the scale suggested by "Ruricola," and find that it amounts to rather more than the sum which the Union has agreed to pay; but that sum is so very low, that I do not think that his scale, even with the alteration I have suggested, would be too high. This, however, is a question which experience only can decide: the principle, I think, is unobjectionable, and I therefore hope that some of the Medical Associations will print his letter for general distribution.—I remain, sir,

Your obedient servant,

FREDERICK H. SANKEY.

Wingham, Feb. 15, 1836.

SELF-SUPPORTING MEDICAL INSTITUTION.

An institution of this kind has been established at Portsmouth, but we confess we cannot help having our doubts as to its stability, when we observe the only apparent source of its finances. The "Rules," a copy of which we have before us, open in this way:—"Every individual (without children) one penny per week. Every husband and wife (without children) one penny each per week. Every widow or widower, with one child, one halfpenny each per week. Every man and wife, with one child, one halfpenny each per week; and for every additional child one halfpenny, till the family shall amount, including parents, to six in number; after which, no additional charge will be made for children under 18 years of age." After stating several other regulations as to the parties eligible to the benefits of the institution, and the sums respectively which they must pay, it is added—"For the above small subscriptions, the undersigned engage to find every working hand residing in Portsmouth, Portsea, Southsea, and Landport (who cannot afford to pay for medical attendance in the regular way), as good advice as the town can produce." The *undersigned* are two physicians and four surgeons. *If* they can afford to bestow their labour for such emolument as may result from the subscriptions just mentioned, it is well; if, however, their object be to encourage habits of prudence and independence among the humbler classes, it is still better: for any expedient must be desirable which can rescue the poorer portion of the population from the tender mercies of the Poor-law authorities.

ROYAL INSTITUTION.

February 12, 1836.

Dr Grant on the Structure of Fishes.

It is highly gratifying to witness the interest which large and popular audiences now take in matters of natural history and comparative anatomy. The theatre this evening was filled with members and their friends, who all seemed delighted with what they saw and heard. The object of Dr. Grant's discourse was to show that every part of the structure of fishes was peculiarly adapted to the element in which these animals live, and move, and have their being. The lecturer began by describing the structure of the skeleton of fishes—that part which gives support to the whole system. He then proceeded to the muscles—the circulatory apparatus—the nervous system,—and lastly, he noticed the branchial arrangements, and the physiology of the swimming bladder, which he seems to consider as bearing some analogy to the lungs of warm-blooded animals. We very much admired the order and method adopted by Dr. Grant in this lecture, and the tact with which he availed himself of his numerous and highly-valuable illustrative drawings. In conclusion, he amused his hearers with a lively account of the importance of fishes in the scale of creation: he showed that, in addition to the abundant prey which the inhabitants of the deep make of all those beings below them living in the same element, by far the greatest number of animals belonging to earth and air, are

destined to be food for fishes; and he ended with the startling announcement, that perhaps the remains of the great Alexander might be traced to the same destination.

PROTEST OF THE STUDENTS OF LONDON UNIVERSITY,

AGAINST THE LATE PROCEEDINGS AT THE CROWN AND ANCHOR MEETING.

To the Editor of the Medical Gazette.

SIR,

We have great pleasure in forwarding to you the accompanying paper, signed by a large number of the medical students of the London University, who are desirous of disclaiming all connexion with the originators and proceedings of the meeting of medical students, held at the Crown and Anchor Tavern, on Monday the 18th of January.

We have the honour to be, sir,
Your very obedient servants,
ALFRED LEGGATT.
JOHN THOMAS DARVILL.

Feb. 17th.

"A report having been widely circulated, that the medical students of the London University were highly instrumental in causing and supporting the meeting of medical students, held at the Crown and Anchor Tavern, on Monday the 18th of January, we the undersigned students of medicine in the London University, do hereby disclaim all connexion with its originators and proceedings."

Signed by 197 *students.*

[The original document, with the autograph signatures attached, has been forwarded to us: we regret we have not room to give the names at length.—ED. GAZ.]

MORISON'S PILLS.

ANOTHER VERDICT OF MANSLAUGHTER.

A CORONER'S inquest was held this week, in the workhouse at Radcliff, on the body of Captain Mackenzie, aged 32, who died in consequence of large doses of Morison's pills, administered to him by a man of the name of Salmon, a "Hygeian agent." The proceedings occupied the better part of five days; much evidence on both sides being heard. The verdict was, "Manslaughter against Robert Salmon, for the improper and incautious administration of large doses of Morison's pills to the deceased, by which he caused his death." One of the Morisonian witnesses stated that he (witness) had swallowed 1000 of the pills in twenty days!

ROYAL BIRMINGHAM SCHOOL OF MEDICINE.

THE Birmingham school now rejoices in a *royal* title. We perceive that in accordance with a petition to the King, numerously signed, and with some noble names among the signatures, his Majesty has been pleased to become the Patron of the school. Sir Herbert Taylor's letter, signifying the King's acquiescence, is dated the 22nd ult.

Rain fallen, ·3 of an inch.

CHARLES HENRY ADAMS.

NOTICES.

MR. PORTWINE ought to have more sense than to send us a letter utterly unfit for our pages: he has no right to indulge in coarse personalities towards a gentleman of whom he knows nothing, and who never once mentioned his name.

The letter *to Mr. Meade* is too long for publication, even if we were to permit our Journal to be made a medium of communication with that gentleman. We wish the writer had adopted some more brief form of exposure.

WILSON & SON, Printers, 57, Skinner-St. London.

LECTURES ON MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XXII.

IODINE.

General History.—Iodine was discovered in 1811 by M. Courtois, a saltpetre manufacturer at Paris. It was first described by Clement in 1813, but was afterwards more fully investigated by Davy and Guy Lussac. It was named Iodine, from ἰωδης, violet-coloured, on account of the colour of its vapour.

Native state.—It exists in both kingdoms of nature.

(*a*) *In the inorganized kingdom.*—Vauquelin met with iodide of silver in a mineral brought from Mexico, and Mentzel found iodine in an ore of zinc which contained cadmium. In sea water it has also been discovered, where it probably exists as an iodide of sodium or of magnesium. Many mineral waters likewise contain it. In the carbonated chalybeate of Bonnington it was detected by Mr. Copeland. About one grain of iodine was found by Dr. Daubeny in ten gallons of the water of Robbin's Well at Leamington, in Warwickshire. In the old well at Cheltenham the quantity was not more than one grain in sixty gallons. In a brine-spring at Nantwich, in Cheshire, there was about a grain of iodine in twelve gallons. In the sulphurous water of Castel Nuovo d'Asti, iodine was discovered by Cantu. In some of the mineral waters of Germany, Bavaria, and South America, it has also been detected. Fuchs found it in the rock salt of the Tyrol.

(*b*) *In the organized kingdom.*—Of *animals* containing iodine I may mention the genera *spongia*, *gorgonia*, *doris*, and *venus*: likewise *sepia*, the envelopes of the eggs of which, contain it. A very considerable number of *vegetables*, particularly those belonging to the family *algæ*, yield it. The following are some instances:—*Fucus vesiculosus*, *f. serratus*, and *f. nodosus*; (fig. 91 *a*, *b*, *c*.)

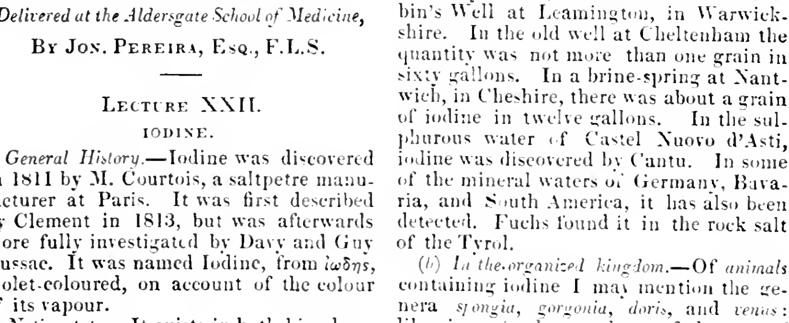

FIG. 91.

a, Fucus vesiculosus,
b, F. nodosus.
c, F. serratus.
d, Laminarla digitata.

laminaria saccharina, and *l. digitata*; (fig. 91, *a*) *halidrys siliquosa*; *chorda Filum*; *gelidium cartilagineum*; *halyseris polypodioides*; *phyllophora rubens*; *rhodomenia palmata*; *ulva Linza*; *porphyra umbilicalis*; *and padina Pavonia*: some of the marine confervæ—*gigartina helminthocorton*, *zostera marina*, &c.

Preparation.—The iodine and iodides of commerce are obtained from the *fucoideæ* (one of the orders of the family *algæ*). These, by combustion, yield an ash or cinder, commonly denominated *kelp*, which contains iodine. Davy states that French kelp is more productive than British; and Eklond, from experiments made at the Cape of Good Hope, concludes that the *laminaria buccinalis* yields more than any European algæ.

Kelp is a very heterogeneous substance. Its soluble parts are the chlorides of sodium and potassium, carbonate of soda, sulphates and nitrates of soda and potash, and the sulphuret and iodide of potassium or of sodium. The quantity of iodide, however, is very small in comparison with the other salts, and, therefore, the first object in the manufacture of iodine is to separate as much of these as possible. By repeated crystallizations we readily attain this, since the iodide being very soluble is left in the mother liquor, along with the sulphuret and a portion of the other salts.

This liquor is introduced into a stoneware still, sulphuric acid and the peroxide of manganese added, and heat applied. Iodine distils over, and after being washed with water, is dried between folds of bibulous paper.

The following is the *theory* of the process. —The mother liquor contains in solution a portion of all the soluble salts of kelp: when, therefore, the sulphuric acid is added, various gases are evolved, while the sulphates of potash and soda are left in the still. Thus the chlorides give out muriatic acid; the sulphurets, hydrosulphuric acid; the carbonates, carbonic acid; the nitrates, the nitric acid; and the iodides, the hydriodic acid. By the mutual action of the muriatic and nitric acids, we obtain chlorine and nitrous acid: by the action of the peroxide of manganese on the hydriodic acid, we obtain water, iodine, and the protoxide of manganese: the latter unites with sulphuric acid, while the iodine distils over. The mutual action of iodide of potassium, sulphuric acid, and peroxide of manganese, is shown by the following formula.

Reagents.	Results.
K I	I
$2\,\dddot{S}$	$\dot{K}\,\dddot{S}$
$\ddot{M}$	$\dot{M}\,\dddot{S}$

From this you observe, that one atom of iodide of potassium, two of sulphuric acid, and one of peroxide of manganese, yield one of iodine, one of the sulphate of potash, and one proto-sulphate of manganese.

Properties. — Iodine is a crystallizable solid, its primary form being a rhombic octahedron. It is usually met with in micaceous, soft, friable scales, having a greyish black colour, a metallic lustre, an acrid hot taste, and a disagreeable odour somewhat similar to that of chlorine. It fuses at about 225° F., and at 347° is volatilized, though the vapour rises along with that of water at 212°. Iodine vapour has a beautiful violet colour, and a great specific gravity, namely 8·716, according to Dumas. Iodine requires 7000 times its weight of water to dissolve, but alcohol and æther are much better solvents for it. Its atomic weight is about 126.

Characteristic tests.—In the free state, iodine is distinguished from other bodies by its forming an intense blue colour with starch. So delicate is this test, that Stromeyer says, water which does not contain more than $\frac{1}{450000}$ of its weight of iodine, acquires a perceptibly blue tinge on the addition of starch. This blue colour is destroyed by heat, and, therefore, in testing for iodine, the liquids employed should be cold: an excess of alkali also destroys it, by forming two salts, an iodate and an iodide, but by supersaturating with acid, the colour is restored.

When iodine is in combination (as with oxygen, or with bases), starch will not recognize it: for example, if a little starch be added to a solution of iodic acid, no change of colour is observed; but if some deoxidating substance be now employed (such as sulphurous acid or morphia) the blue colour is immediately produced. On a future occasion I shall show you the advantage to be taken of this in medico-legal inquiries. If the iodine be combined with a base (as potassium, or sodium), chlorine or nitric acid must be employed to remove the latter; and the iodine being then set free, will re-act on the starch. If you wish to detect iodine in the urine of a patient, the mere addition of starch will not suffice: you must employ also nitric acid, or chlorine, to remove the base with which the iodine is combined.

The blue compound of iodine and starch is usually designated the *iodide of starch*, but Raspail objects to the term; as grains of starch consist of two parts—an *external envelope*, within which is a *soluble gummy substance*. Now the iodine, says Raspail, attaches itself to the envelope only, giving it a blue colour, just as it

gives a yellow colour to other organic textures.

Purity. — We are told that iodine is much adulterated, but I doubt it. There are two properties which will, in most instances, determine its purity—namely, its solubility in alcohol, and, when heated, its giving out a violet vapour, and leaving no residuum. Coal, plumbago, peroxide of manganese, sand, and charcoal (all of which, it is said, have been found in iodine), would be in this way readily distinguished. But Dr. O'Shaughnessy states, that he met with one specimen so artfully adulterated, that the foreign ingredients were at the same time soluble in alcohol and volatilized by heat. A little imposition may be, and indeed is, practised by some dealers in iodine, by selling it in the moist state. An ounce, if very moist, may contain one drachm, or perhaps even a drachm and a half, of water. The easiest way of detecting this, is by compression between folds of blotting paper.

Physiological effects. — (*a*) *On vegetables.*— It has been supposed that the aqueous solution of chlorine promotes germination by indirectly yielding oxygen to the seed, and it was suspected that iodine acted in a similar manner. Cantu, professor of chemistry in the University of Turin, put this to the test of experiment, and inferred that seeds watered by a solution of iodine germinate more quickly than those watered by a solution of chlorine; iodine was detected in the plant in the state of hydriodic acid. Reasons, which I need not here detail, lead me to doubt whether either chlorine or iodine have this property of accelerating germination. Indeed, Vogel says that iodine, so far from quickening, actually checks or stops the process.

(*b*) *On animals.*—Hitherto no examination has been made of the effects of iodine on the different classes of animals, for, with the exception of man, dogs are the only animals on which it has been tried. On them its operation appears to be that of an irritant and caustic poison, though not of a very energetic kind. Magendie threw a drachm of the tincture into the veins without any apparent effect: 72 grains of solid iodine were applied by Orfila to a wound on the back of a dog; local inflammation, but no other inconvenience, resulted. One or two drachms administered by the stomach caused vomiting, and when this was prevented by tying the œsophagus, ulceration of the alimentary canal, and death, took place.

(*c*) *On the human subject.*—The effects on the human subject vary according to the dose. When administered in *small or medicinal doses,* we sometimes obtain the palliation, or even the removal of disease, without the least alteration in the functions of the body. Thus I have seen it taken daily for twelve months with evident advantage, in diminishing the size of a chronic tumor, without my being able to perceive any functional effect. Sometimes it increases the appetite, from which circumstance it has been denominated a *tonic.* But the long-continued use of it is said to bring on a slow kind of gastro enteritis; an effect which has been occasionally observed, though I believe it to be rare, and only met with when the remedy has been incautiously administered. The action of it on the organs of secretion does not appear to be constant; at least I can in no other way account for the contradictory statements made. Some writers (Jörg and Lugol, for example) ascribe to it a *diuretic* operation, while others (for instance, Dr. Coindet) have not observed this effect. Coindet, Sablairoles, Brera, and Magendie, call it *emmenagogue.* Dr. Manson, however, does not believe that it has any specific influence over the uterus, but ascribes its emmenagogue effects to the stimulant and tonic action which it exercises over the whole body. In one case, he tells us iodine occasioned so much sickness and disorder of stomach, that the menstrual discharge was suppressed altogether. The pulse is not usually affected, but in some instances becomes accelerated. *Salivation* has occasionally taken place: Lugol says he has seen it in several cases, the patients being generally males. Two instances have been recently mentioned in the Medical Gazette, one by Mr. Winslow, and the other by Dr. Ely, (in the latter the patient was a female). *Absorption of the mammæ* has also been observed. Three cases of this are reported in Hufeland's Journal; one of which may be mentioned. A healthy girl, 20 years of age, took tincture of iodine during six months for a bronchocele, of which she became cured; but the breasts were observed to diminish in size, and notwithstanding she ceased to take the remedy, the wasting continued, so that at the end of two years not a vestige of the mammæ remained. Sometimes the breasts waste, though the bronchocele is undiminished: Reichenau, in Rust's Magazine, relates the case of a female, aged 26, whose breasts began to sink after she had employed iodine for four months, and within four weeks they almost wholly disappeared, yet her goitre remained unaffected. *Wasting of the testicles* is another effect attributed to iodine. Some have ascribed an *aphrodisiac* operation to it, but Kolley, a physician at Breslau, who took large quantities for a bronchocele, denies that it had any such operation on him.

Let us now examine the *poisonous effects of iodine.* Occasionally during the medicinal employment of iodine, various

symptoms (called by Dr Coindet, *iodic*) have occurred, which, by endangering the patient's safety, rendered the suspension of the medicine absolutely necessary. Violent vomiting and purging, with fever, palpitation, rapid and extreme emaciation, cramps, and small and frequent pulse, occasionally with dry cough, are the symptoms described, and which constitute the state denominated *iodism.* This condition, however, must be a very rare occurrence, for it is now hardly ever met with, notwithstanding the frequency and the freedom with which the remedy is employed. I have seen iodine administered in some hundreds of cases, and never met with one in which either iodism or wasting of the mammæ, or of the testicle, occurred. Dr. Coindet says that during this state bronchoceles are sometimes rapidly diminished. Swallowed *in large doses,* iodine operates as a powerful irritant, or rather corrosive, poison, giving rise to symptoms similar to those produced by the concentrated mineral acids.

Modus operandi.—That iodine becomes absorbed, when employed either externally or internally, we have indisputable evidence, by its detection not only in the blood, but in the secretions. Cantu has discovered it in the urine, sweat, saliva, milk, and blood. In all cases it is found in the state of iodide, or hydriodate. Bennerscheidt examined the serum of the blood of a patient who had employed for some time iodine ointment; but he could not detect any trace of iodine. In the crassamentum, however, he obtained evidence of its existence, by the blue tint communicated to starch.

A curious circumstance is mentioned by Dr. C. Vogel, in the fourteenth volume of Rust's Magazine, of a lady, 28 years of age, of a yellow complexion, who, from the internal employment of the tincture of iodine, became suddenly brown, besides suffering other morbid symptoms. After some days the skin had the appearance of having been smoked!

I have already mentioned that iodine is a local irritant: in further proof of this I may mention the following facts. When rubbed on the skin it causes redness, with desquamation of the cuticle. Inhaling the vapour (diluted with air) excites cough, and increased secretion of bronchial mucus.

It seems to have a specific effect on the nervous system; for Lugol says he has observed headache, drowsiness, a kind of intoxication, and even stupor, produced by the use of ioduretted baths. Moreover, when an over-dose of iodine has been taken, or as a consequence of the accumulated effect of small doses, cramps occur. The sexual system has been said to be specifically affected by iodine, on the ground that this medicine is an emmenagogue and aphrodisiac, and that it sometimes occasions wasting of the testicles and mammæ. The rapid emaciation occasionally caused by iodine, as well as the disappearance of visceral and glandular enlargements, have given rise to an opinion that iodine stimulates the lymphatic vessels and glands. Lugol, on the other hand, asserts, that instead of producing emacia ion, it encourages the growth and increase of size. I have never seen either emaciation, or the reverse state, caused by its exhibition.

Uses. — (*a*) In the first place, concerning the employment of iodine in *bronchocele.* Of all remedies yet proposed for bronchocele, this has been by far the most successful. Indeed, judging only from the many cases published illustrative of its efficacy, we should almost infer it was a sovereign remedy. However, it is to be recollected that of those who have written on the use of iodine in this complaint, some only have published a numerical list of their successful and unsuccessful cases. Bayle, in his "*Bibliothèque de Therapeutique,*" has given a summary from the writings of Coster, Irmenger, Baup, Manson, and others, from which it appears that of 364 cases treated by iodine, 264 were cured. I much regret, however, that my own experience does not accord with this statement. I have more frequently seen iodine fail than succeed in bronchocele; and I know many others whose experience has been similar. Dr. Bardsley cured only nine, and relieved six, out of thirty cases. I do not, however, doubt but that others have been more successful. To what circumstance, then, ought we to attribute this variable result? I think probably to a variation in the nature of the disease; for under the common head of bronchocele, goître, or Derbyshire neck, are included very different conditions of the thyroid gland. In some cases this organ, though enlarged, appears to be perfectly healthy in its structure. In others tumefaction of the gland takes place suddenly, and may even disappear as suddenly, from which it has been inferred the enlargement depends on an accumulation of blood in the vessels, and effusion of serum into its tissue. Coindet mentions a goître which was developed excessively during the first pregnancy of a young female: twelve hours after her accouchement it had entirely disappeared. Now I can readily believe that iodine may be more beneficial in either of these kinds of bronchocele, than in those accompanied with new or accidental productions; for some bronchoceles have within them osseous, cartilaginous, fibrous, or fluid deposits; and in some cases the thyroid gland has assumed a schirrous condition.

Now in any of these instances iodine is less likely to be serviceable. Kolley, the physician already mentioned, who was himself cured of a large goitre of ten years' standing, says, that for iodine to be useful, the bronchocele should be recent, and not painful to the touch; the swelling confined to the thyroid gland, and not of a schirrus nature, nor containing any stony or other concretions; and that the general health be not disordered.

If the swelling be tender to the touch, and have other marks of inflammation, let the usual local antiphlogistic measures precede the employment of iodine. You may administer this agent either internally or externally. Commonly, however, both modes of exhibition are resorted to. The most effectual method of employing iodine externally is that called *endermic*, already described; namely, to apply an ioduretted ointment (usually containing iodide of potassium) to the cutis vera, the epidermis being previously removed by a blister. But the *epidermic*, or *iatroleptic* method, is more usually followed—that is, the ioduretted ointment is rubbed into the affected part, without the epidermis being previously removed.

(*b.*) *Scrofula* is another disease for which iodine has been extensively used. Dr. Coindet was, I believe, the first to direct public attention to the efficacy of this method of treatment. Subsequently, Baup, Gimelle, Kolley, Sablairoles, Benaben, Callaway, and others, published cases illustrative of its beneficial effects. Dr. Manson deserves the credit of having first tried it on an extensive scale. He treated upwards of eighty cases of scrofula and scrofulous ophthalmia by the internal exhibition of iodine, sometimes combined with its external employment; and in a large proportion of cases, where the use of the medicine was persevered in, the disease was either cured or ameliorated, the general health being also improved. Three memoirs on the effects of iodine in scrofula have been subsequently published by Lugol, physician to the Hôpital St. Louis, serving to confirm the opinions already entertained of its efficacy. From the first memoir it appears, that in seventeen months—namely, from August, 1827, to December, 1828 — 109 scrofulous patients were treated by iodine only; and that of these, 36 were completely cured, and 30 relieved; in 4 cases the treatment was ineffectual, and 39 cases were under treatment at the time of the report made by Serres, Magendie, and Dumeril, to the Academie Royale des Sciences. In his illustrative cases, we find glandular swellings, scrofulous ophthalmia, abscesses, ulcers, and diseases of the bones, were beneficially treated by it. Lugol employs iodine internally and externally: for internal administration, he prefers iodine dissolved in water by means of iodide of potassium, given either in the form of *drops*, or largely diluted, under the form of what he calls *ioduretted mineral water*, presently to be described. His external treatment is of two kinds; one for the purpose of obtaining local effects only, the other for procuring constitutional or general effects. His local external treatment consists in employing ointments or solutions of iodine: the *ointments* are made either with iodine and iodide of potassium, or with the protiodide of mercury; the *solutions* are of iodine and iodide of potassium in water; and according to their strength are denominated caustic, rubefacient, or stimulant: the rubefacient solution is employed in making cataplasms and local baths. His external general treatment consists in the employment of *ioduretted baths*. Of these different preparations more will be said hereafter.

(*c.*) As an *emmenagogue*, iodine has been found a powerful agent by Coindet, Brera, Sablairoles, Magendie, and others. I need hardly say, that as suppression or retention of the catamenia may arise from many, and even opposite causes, neither iodine nor any other remedy can be expected invariably to succeed. Magendie states, that a young lady to whom he administered it, and whose propriety of conduct he had no reason to doubt, miscarried after using it for three weeks.

(*d.*) In various *chronic diseases of the viscera*—such as enlargements of the liver, spleen, uterus, and testicles—iodine has been beneficially employed.

(*e.*) In *gonorrhœa* and *leucorrhœa*, when the inflammatory symptoms have subsided.

(*f.*) In the *venereal disease*, advantage has been obtained in the treatment of buboes, diseased testicles, &c.

(*g.*) *Inhalations of the vapour* of iodine have been employed in chronic pulmonary complaints—as phthisis and chronic bronchitis. In a former lecture I described the method of using them.

(*h.*) *In several forms of disease of the nervous system*, as chorea and paralysis, this remedy has been beneficially employed by Dr. Manson, and others.

(*i.*) Several cases of *cancerous* diseases are reported to have been relieved by the use of iodine.

(*j.*) *As an antidote in cases of poisoning* by strychnia, brucia, or veratria, Donne has proposed to administer the tincture of iodine or of bromine, since the iodides of these alkalies are much less active (so, at least, he says) than the alkalies themselves.

(*k.*) Notwithstanding the numerous cases thus treated by iodine, many others are recorded, but of which I shall only no-

tice the following:—In old non-united fractures, to promote the deposition of ossific matter, it has been used by Mr. Cross and Mr. Buchanan; in various chronic skin diseases it has been employed with benefit, more particularly those occurring in scrofulous subjects; in gout and chronic rheumatism, &c. &c.

Administration.—Iodine is rarely used alone, but generally in combination with the iodide of potassium: formulæ for the conjoint exhibition of these I shall give when I have spoken of the iodide: at present I shall confine myself to those preparations into which iodine alone enters.

(*a.*) *Tincture of iodine.*—This is a simple solution of iodine in rectified spirit, and may be made of various strengths. In the Dublin Pharmacopœia, the proportions are two scruples of iodine to one ounce of spirit. It is, however, an objectionable preparation; for, in the first place, by keeping, part of the iodine is deposited in a crystalline form, so that the strength is apt to vary; secondly, it undergoes decomposition, especially when exposed to solar light; the iodine abstracts hydrogen from the spirit, and forms hydriodic acid, which, acting on some spirit, forms a little hydriodic æther. These are not the only objections: when added to water, the iodine is deposited in a solid state, and may thus irritate the stomach. It is used both externally and internally: externally it may be mixed with the soap liniment, and internally it is exhibited in doses of from five or six drops to half a drachm. Each drachm contains five grains of iodine.

(*b.*) *Ointment of iodine.*—This is composed, according to the Dublin Pharmacopœia, of a scruple of iodine to an ounce of lard. If this be too irritating, the quantity of lard must be increased. The colour of this compound is brown, but, by keeping, it becomes paler; and hence should always be made when wanted.

Antidotes.—In the event of poisoning by iodine, or its tincture, the first object is to evacuate the poison. For this purpose, assist the vomitings by the copious use of demulcent liquids—for example, milk, eggs beat up with water, barley water, &c. As starch and iodine unite to form a blue compound, Buchner thinks it probable that the action of the iodine on the animal organism is weakened by this combination; and he therefore advises the exhibition of starch or flour, boiled in water, to the consistence of a thin paste. Magnesia is also recommended. Opiates have been found useful. Of course you must combat the gastro-enteritis by the usual means.

Iodide of Potassium.

Synonymes.—This salt is sometimes called *ioduret of potassium*, and in commerce is usually denominated *hydriodate of potash*.

Preparation.—Various methods of procuring it have been proposed. I believe Dr. Turner's is the best; it is as follows:—Add to a hot solution of pure potash as much iodine as the liquid will dissolve, by which means a reddish-brown fluid is obtained. Then pass sulphuretted hydrogen through the liquid, until it becomes colourless. Apply a gentle heat, to expel any excess of sulphuretted hydrogen; filter to get rid of the free sulphur, and exactly neutralize the free acid present, with potash; then crystallize.

The *theory* of the process is this: when iodine is added to potash, two salts are generated; five atoms of potash being decomposed, the five of potassium contained therein unite with five of iodine, to form five of the iodide of potassium; while the five of oxygen of the decomposed potash, combining with one of iodine, generate one of iodic acid, which, with one of potash, forms iodate of potash. These changes are thus shewn:—

Reagents.	Results.
$6\ \dot{K}$	$5\ K\ I$
$6\ I$	$\dot{K}\ \overset{\cdot\cdot\cdot\cdot\cdot}{I}$

To decompose the iodate, sulphuretted hydrogen is passed through the solution; the oxygen of the iodate, with the hydrogen of the sulphuretted hydrogen, forms water; sulphur is deposited, and iodide of potassium is left in solution.

Reagents.	Results.
$\dot{K}\ \overset{\cdot\cdot\cdot\cdot\cdot}{I}$	$K\ I$
$6\ S\ H$	$6\ \dot{H}$
	$6\ S$

Dr. Turner has subsequently somewhat modified this process, though I think for commercial purposes that just described is the best. His present plan is the following:—"Add iodine to a hot solution of pure potassa until the alkali be neutralized, when iodide of potassium and iodate of potash are generated; evaporate to dryness, and expose the dry mass, in a platinum crucible, to a red heat, in order to decompose the iodate. The fused mass is then dissolved out by water, and crystallized." The objection to this process is, that if too much heat be employed, part of the iodide will be volatilized; and if too little, part of the iodate will not be decomposed.

Properties.—The fundamental form of the crystals of this salt is a cube; and it is usually met with either in this form or in

that of an octahedron. The salt is white and opaque, but by slow crystallization may be obtained perfectly transparent. It contains no water of crystallization, but some water mechanically lodged between the plates of the crystals, so that it decrepitates when heated. It is fusible, volatile, and very soluble in water. At 60°, 100 parts of water will dissolve about 140 parts of the salt: it is also readily soluble in alcohol. The taste of this salt is acrid and bitter.

Composition.

1 atom Iodine	126
1 atom Potassium	40
1 atom Iodide of Potassium	166

Characteristic tests.—The following tests will prove that this is an iodide, or hydriodate salt:—(*a*) With a solution of corrosive sublimate it occasions a vermillion-red precipitate of the biniodide of mercury, which is very soluble in excess of the iodide of potassium. (*b*) With the sugar of lead it forms a yellow precipitate of the iodide of lead. (*c*) With the nitrate of silver, a yellow precipitate of the iodide of silver. (*d*) With the protonitrate of mercury or calomel, a greenish-yellow precipitate of the protiodide of mercury. (*e*) On the addition of starch and a few drops of either nitric acid, or of a solution of chlorine, the blue iodide of starch is formed. (*f*) Chloride of platinum produces the iodide of platinum, which is of a brownish-red colour.

To prove that the base of the salt is potassium, or potash, the following tests may be employed:—(*a*) Perchloric acid occasions a white precipitate of perchlorate of potash, while the liquid becomes yellowish-brown. (*b*) An excess of a strong solution of tartaric acid also occasions a white precipitate of the bitartrate of potash. (*c*) Carbazotic acid forms yellow needle-like crystals of carbazotate of potash. (*d*) Soak a pack-thread in the solution of the iodide; then dip the wetted end into melted tallow, and apply it to the exterior cone of the flame of a candle: a pale violet tinge is given to the flame.

Adulteration and impurity.—Iodide of potassium is rarely met with in commerce quite pure, for we may generally detect minute portions of the carbonate of potash. In the year 1829, I published in the Medical and Physical Journal an analysis of a commercial salt, which contained 77 per cent. of the carbonate. Others also have detected the same impurity. Dr. Christison found 74·5 per cent., and Dr. O'Shaughnessy 64 per cent. It is reported that this very impure salt is furnished by a Scotch manufacturing company. The following anecdote will shew that the pure is more active than the impure salt. Soon after I had discovered the gross adulteration just mentioned, I was told by a surgeon that he had prescribed the iodide of potassium in very large doses, without any obvious effect; and that he suspected the salt employed was that which I had described. I suggested that he should call at the druggist's where the prescription was made up, and test the salt. He did so, and found, as we suspected, it was adulterated. He requested a purer kind to be procured, with which, in future, Mrs. ——'s prescriptions should be prepared. The next day he was sent for in great haste to see his patient, who, it was believed, had been poisoned. The fact was, she had taken her usual dose of medicine, but made with the pure salt, and which had occasioned violent vomiting; though no serious effects resulted.

There are several modes of detecting the impurities: one is to expose the suspected salt to a full red heat, when the iodide will be volatilized, leaving the impurities. The solubility of the iodide in alcohol will serve to recognise the presence of those salts (as the carbonate of potash), which are not soluble in this menstruum.

The easiest method of detecting a carbonate in the iodide, is to place a small portion of the latter in a glass, and add lime-water. If the salt be pure, no change will be observed; but if any carbonate be present, a precipitate is produced. Any sulphate present may be detected by chloride of barium, which will occasion a white precipitate (sulphate of barytes) insoluble in nitric acid. To detect the muriates or chlorides, add nitrate of silver, collect the precipitate, and digest in ammonia; filter the ammoniacal liquid, and add nitric acid; if any chloride be present, a white precipitate will be produced. The theory of this latter test is this: nitrate of silver precipitates the iodides, the chlorides, and the carbonates; ammonia will dissolve any chloride or carbonate of silver, but not the iodide. On the addition of nitric acid to the ammoniacal solution, the chloride is thrown down, while the carbonate is converted into the nitrate of silver.

Dr. Christison has described a commercial kind of iodide, which has an excess of iodine, and, therefore, whose colour is yellowish, and odour strong. I have met with this; indeed, here is a specimen which I purchased of a chemist in this city.

Physiological effects.—Devergie has shewn that this salt is an irritant and corrosive poison, like iodine. Four grains in solu-

tion, thrown into the jugular vein of a dog, produced tetanus and death in a minute and a half. Two drachms, dissolved in water, killed a dog in three days, by causing inflammation of the stomach. The constitutional or remote effects are probably similar to those of iodine, and hence this salt may be employed in the same cases.

Modus operandi. — It becomes absorbed, and may be detected in the urine. A very curious fact also has been noticed; it may be found in the urine several days after it has been administered.

Uses.—It is employed in the same cases as iodine. In the treatment of rheumatism, and also of some of the secondary symptoms of syphilis (as eruptions, nodes, &c.), it has been found useful; in the latter complaints, especially when combined with sarsaparilla.

Dose from one to five grains. However, I have seen it given in much larger doses than this.

Administration.—Iodide of potassium may be employed alone or in combination with iodine.

1st. *Preparations of the iodide of potassium only:* (*a.*) *Solution.*—As this salt is soluble both in water and spirit, either liquid may be employed for dissolving it, and the strength may be varied at pleasure. Magendie's formula is thirty-six grains of the iodide dissolved in an ounce of water; and he says two or three ounces may be taken daily, without the least injury. To this solution you may add, when necessary, the tincture of foxglove. In scrofulous affections, a good mode of exhibiting the iodide is by solution in some bitter infusion.

(*b*) *Ointment of the iodide of potassium.*—In the Dublin Pharmacopœia this is prepared by rubbing together a scruple of the iodide and an ounce of lard; but you will sometimes find it useful to increase the strength to a drachm. This ointment undergoes change by keeping, acquiring a yellow colour; most probably by the separation of a little free iodine.

2. *Preparations of iodide of potassium with iodine.*—These are more active, energetic, and useful preparations than those containing either iodine, or the iodide solely.

(*a*) *Solution of the ioduretted iodide of potassium.*—Iodine readily dissolves in water, holding in solution the iodide of potassium, and this is, I believe, the best mode of exhibiting it internally. The strength may be varied at pleasure. I shall describe several preparations, some for external, others for internal use.

Ioduretted mineral water. — This is a favourite preparation of Lugol's: he uses it of three different degrees of strength.

	No. 1.	No. 2.	No. 3.
℞ Iodine..........	gr. $\frac{3}{4}$.	gr. j.	gr. $1\frac{1}{4}$.
Iodide potassium	gr. $1\frac{1}{2}$.	gr. ij.	gr. ij$\frac{1}{2}$.
Distilled water ..	℥viij.	℥ viij.	℥ viij.

The solutions are yellowish or orange-coloured, and quite transparent. When sweetened it is readily drunk by children; but it must be recollected sugar occasions in a few hours decomposition, and, therefore, it should only be sweetened when about to be drunk. From six to eight ounces of this solution are given daily.

Ioduretted drops.—By this I mean a strong solution of iodine and iodide of potassium in water, so that a few drops may be taken for a dose. Here is a formula for making the liquid denominated *solution of ioduretted hydriodate of potash,* or *Coindet's solution.* Dissolve 36 grains of iodide of potassium in an ounce of distilled water, and then add 10 grains of iodine. The dose of this is from 10 to 50, or 60 minims, three or four times a day.

Caustic, rubefacient, or stimulant solutions.—These I have already alluded to as being employed by Lugol.

	Stimulating Washes. No. 1.	2.	3.	*Rubefacient Solution.*	*Caustic Solution.*
Iodine	gr. ij.	gr. iij.	gr. iv.	ʒ iv.	℥ j.
Iodide of potassium	gr. iv.	gr. vj.	gr. viij.	℥ j.	℥ j.
Distilled water	lb. j.	lb. j.	lb. j.	℥ vj.	℥ ij.

Lugol uses the stimulating washes in scrofulous ulcers, ophthalmia, fistulous abscesses, &c. When the scrofulous surfaces require stronger excitement than usual, he employs the rubefacient solution. In tubercular tumors which have obstinately resisted all other means of treatment, the rubefacient solution may be applied in admixture with *cataplasms* of linseed meal. To prepare the mixture, the poultice is first made in the ordinary manner; and when moderately cool, a sufficient quantity of the rubefacient liquid is poured on it with a wooden measure. The caustic solution is used for touching the eye-lids and nasal fossæ, to repress excessive granulations, &c. &c.

Ioduretted baths.—I have already alluded to these as being employed by Lugol, in the treatment of scrofula. They are to be made in wooden vessels.

IODURETTED BATHS FOR CHILDREN.

Age.	*Water.*	*Iodine.*	*Iodide of Potassium*
	(Quarts.)	(Troy Grains.)	(Troy Grains)
4 to 7	36	30 to 36	60 to 72
7 .. 11	75	48..60..72	96..120..144
11 .. 14	125	72..96	144..192

IODURETTED BATHS FOR ADULTS.

Degree.	*Water.*	*Iodine.*	*Iodide of Potassium.*
	(Quarts.)	(Drachms Troy.)	(Drachms Troy.)
No. 1.	200	2 to 2½	4 to 5
No. 2.	240	2..2½..3	4..5..6
No. 3.	300	3..3½	6..7

(*b*) *Iodurretted ointment.*—This may be made by adding from 10 to 20 grains of iodine to the ointment of the ioduret of potassium already described.

Antidote.—If a case of poisoning by the iodide of potassium should occur, the treatment should be the same as for iodine, already described.

OBSERVATIONS

ON

LOCAL AND GENERAL BLOOD-LETTING.

By M. Lisfranc.

Application of Leeches to various parts of the Body—Enumeration of situations in which their application is inconvenient and dangerous—Remarks on General Bleeding.

When leeches are applied to the face, we incur the risk of producing œdema, if not erysipelas. Thus in ophthalmia, when they are applied too near the middle angle of the eye, they often cause erysipelas, though they may have been employed in great numbers. Again, ought we to employ leeches to the inner surface of the eye-lids, as practised by some oculists? I never do, because I have seen very violent inflammation, and even gangrene, result from it. I am aware, indeed, that such effects are not common, but it is sufficient that they be possible, to justify my condemning the practice. In inflammations about the throat, leeches are usually applied about the neck, where they produce cicatrices, which in women are unseemly. Experience has convinced me that in inflammations either of the larynx or pharynx, leeches, when applied over the mastoid apophyses, and along the roots of the hair, are just as efficacious, while the marks are hid; on the other hand, in children, and in women with very fine skins, leeches may divide superficial veins. Phlebitis may thence result, the more dangerous in proportion as the veins are nearer the heart; hæmorrhage may also take place, and if the part be touched with nitrate of silver, to arrest it, the cauterization may possibly cause phlebitis. It may also happen, that in the absence of a medical man, the persons about the patient may be enabled to stop the bleeding, while if the leeches be placed over the mastoid apophyses, pressure, applied by the most inexperienced and unskilful, can scarcely fail to arrest the hæmorrhage. Leeches are often ordered to the epigastrium in children who have abdominal inflammations, and often they are placed where the skin is most moveable, as just below the edges of the ribs; and this mobility, which depends upon the act of respiration, may give rise to a prolonged hæmorrhage. The leeches ought to be applied lower down, at some distance from the sternum or ribs.

It is also to be remembered (and this holds good in all diseases) that leeches yield but little blood when applied to parts largely supplied with fat. Thus in a very fat person, forty leeches applied to the abdomen in a case of peritonitis, might only increase the determination of blood to the peritoneum, instead of relieving it. Under such circumstances we must at least double the number of leeches, or even pressure, or general bleeding. Never apply leeches where there are many nerves, because this excites pain. Thus with respect to the forearm, they ought to be applied to the dorsal rather than the palmar surface. Never apply leeches within the vagina, for the external veins of the part communicate with the internal, and leeches applied externally bleed as well. When applied to the anus, do not place them too near the margin of the rectum, because the bites, irritated by the intestinal secretions, sometimes ulcerate, and are then very difficult to heal. Never apply leeches to the scrotum, nor on the skin of the penis, for in these situations they give great pain, and sometimes lead to gangrene, an accident by which the reputation of the surgeon cannot fail to suffer.

Never put leeches on the back of the hand or foot, on account of the great number of tendons there; the lower part of the forearm or the upper part of the leg are to be prepared. You must not select the *lower* part of the leg, because if there happen to be a varicose vein in that situation, the leech-bites might lead to incurable ulceration. I never apply leeches to the mamma, because the skin is very fine and sensitive; and I have ascertained that they succeed just as well when applied at a distance.

Let us now pass in review some cases of disease.—Ought leeches to be applied to an inflamed part? We are often directed to do so in erysipelas. But in erysipelas, with phlyctenæ, they often lead to gangrene, and they have also the disadvantage of being very painful, the sensibility of the inflamed surface being in a state of exaltation; besides which, experience has shown that when the leeches are applied beyond the border of the erysipelas, they afford equal relief. Do not apply leeches to œdematous parts, nor to parts which are ecchymosed, though this be but slight, unless you would incur the risk of lighting up gangrenous inflammation. In white swellings, when the skin is adherent to the subjacent textures, never apply leeches upon the tumor, because, as in œdema, the vitality of the part is diminished, and may lead to similar results. Never apply leeches upon a bubo, nor at a less distance than four inches, otherwise you will often have the bites to be converted into syphilitic ulcers. Without attempting to explain this fact, I maintain it; and if I be told that it happens but rarely, I reply that the possibility of the occurrence warrants the rule I have laid down. Do not apply leeches on a fractured limb, for the pressure of the necessary apparatus upon the bites may cause eschars, or greatly retard their healing, and you will thus be greatly embarrassed in applying the splints, &c. Even in hernia there is inconvenience in applying leeches to the part itself. Thus in using the taxis we may be incommoded by the blood, which continuing to ooze, causes the fingers to slip over the skin, or if the bleeding has ceased, the taxis may reproduce it; nay, the manipulation being rendered painful by the bites, may even increase the inflammation of the hernia. The leeches ought, therefore, to be placed beyond the sphere of the rupture; and this method has another advantage also, if an operation becomes necessary within a few hours, or even days. Finally, never put leeches on a schirrous breast, particularly if the schirrus be very near the surface, or occupies the skin, for you may have the bites converted into ulcers of scirrhous character, extremely painful, and increasing the progress of the malady. Place your leeches round the schirrus, and you have nothing to fear. Beware, for the reasons already given, of applying leeches to the neck of the uterus, when it is scirrhous.

When you have reflected on these principles, they will, as it were, become proper to you, and you will not have to learn them hereafter at the risk of your own reputation, or at the expense of your patients. But at a time when so much difference of opinion exists regarding depletion, allow me to make a few practical remarks on this important subject. I would put you on your guard against that spirit of system which has always been so injurious to our science.

In inflammations, general bleeding is the more advantageous in proportion as the inflammation is more directly under the influence of the circulation in the great vessels: it is on this account that it has generally succeeded so well in inflammation of parenchymatous textures. It is not so when the inflammation has its seat in the membranous tissues, especially those which are under the influence of the capillary system: here leeching is usually more efficacious. When, however, we wish to produce a *derivation*, general bleeding is almost always to be preferred. In this case it ought to be small, and practised at a distance from the inflamed part. The proofs by which this derivative principle of bleeding is demonstrated are numerous: I shall state a few of them. Uterine pains may have resisted all our narcotic remedies, and yield to the abstraction of a cupful of blood from the arm. A woman has a violent menorrhagia: we take a little blood by venesection, and the discharge ceases. This effect is almost constant; and it was this which led me to employ those small bleedings which succeed so well in subinflammations of the uterus. What farther proves this derivative effect is, that when the patients dislike the phlebotomy so much as to compel us to substitute leeching, we fail in the great majority of cases.

This derivative mode of bleeding has still more marked effects when it is practised in inflammation with effusion; for not only does it arrest the inflammation, but it empties the veins, and thus renders them greedy of fluids, and thus promotes the absorption of what has been poured out,—as has been proved by the brilliant experiments of M. Magendie.

When applied in large number, leeches unload the tissues, and act as antiphlogistics; but in small number, they produce congestion of the part to which they are applied. The proofs of this are very numerous. 1st. To restore the menstrual discharge, leeches are applied to the

ankles or to the thighs, but not in great number; six or eight at most are used, because it is well known that a larger number would not in general produce the desired effect. 2d. Leeches in small number are much more apt to cause erysipelas than when many of them are used. 3d. Applied in small number to a white swelling in the acute stage, they for the most part prove injurious; but when the disease is chronic, they frequently succeed. 4th. A few leeches aggravate a severe phlegmasia; a large number combat it successfully.

An important fact to be aware of is, that, other circumstances being alike, the action of leeches is not borne so well during health as during the presence of inflammation. This is matter of experience. It may thus be explained. During the state of health, nothing stimulates the vital properties above the degree which is required for the performance of the functions; but during the presence of phlegmasia, there is an unwonted stimulus, which exalts the vital properties, and makes them offer greater resistance to any thing tending to overcome them. When the inflammation subsides, this stimulus which acts upon the vital properties diminishes, and we then see that very small abstractions of blood weaken the patient very much,—a very important fact in a practical point of view.

Some very extraordinary phenomena take place in particular idiosyncrasies. Some patients cannot apply eight or ten leeches without being weak and exhausted during many days; others, on the contrary, bear large and repeated bleedings perfectly well. An individual, labouring under tetanus in this hospital, was bled nineteen times in as many days: the first bleeding amounted to three palettes; the others to one palette each. The patient, within the period specified, had also applied to him 740 leeches! But we could not push the depletion thus far without taking into consideration the state of the circulating system, and the various symptoms which indicated the absence of debility. It is proper to ascertain from patients how they have borne depletion on former occasions. Here is another precept for us to follow: we have recourse to a bleeding, and before we repeat it we must examine the pulse, the complexion, the muscular strength, &c., and thus by caution avoid exceeding what the patient can safely bear.

Depletions are also borne better or worse according to the seat of the disease. This point is of such fundamental importance, that it is necessary to enter into some detail regarding it. In inflammation from wounds, not implicating the viscera, we may proceed a great length in the abstraction of blood. Here there is no internal cause diminishing the vital energies; and bleeding has the effect of preventing or removing inflammation, when it is practised with sufficient energy: we thus often prevent suppuration and all its consequences. But there is a very important indication to observe, namely, that we discontinue to abstract blood whenever suppuration takes place: by neglecting this, we are exposed to a very great risk of causing the reabsorption of the pus, which is often followed by a speedy and fatal termination. I may remark, in passing, that it is also proper at the same time to discontinue the rigid diet, as this also favours absorption. In inflammation of the lungs, and particularly in wounds of these organs, it is a well-known fact that bleedings may be employed to a great extent, unless there be tubercles. Military surgeons have carried these depletions very far, but their works are too little read. In the army, I used, in cases of this kind, to practise first one large bleeding, and then, during the day, it might be ten different times, have taken two or three table-spoonsful of blood, thus arresting the difficulty of breathing when it has threatened to suffocate the patient. By this method almost all those cases, usually so fatal, recovered.

In inflammation of the brain or its membranes, venesection to a large extent has been recommended; but it is very necessary to distinguish the following case. In many persons bleeding augments the nervous disturbance, and in such cases it is necessary to renounce this remedy, lest we destroy altogether the equilibrium that exists between the sanguiferous and nervous systems. In inflammations of the abdominal viscera, you will do a great deal of harm if you carry your depletions as far as in thoracic or cerebral affections, and for this reason—these inflammations scarcely last for a few hours before the patients are brought into a state of great prostration: there is a peculiar influence exercised over the whole system, probably depending upon the abdomen being the seat of the digestive function. No inflammation so frequently assumes the adynamic form, as those which have their seat in the abdomen. Now, whenever an abdominal inflammation is of some days' standing, and proves obstinate, we must carry our bleedings to a much less extent than in the inflammation of other parts*.

---

* The above, as well as the lecture by M. Lisfranc in our last number, has been taken from the *Gazette des Hôpitaux.*

OBSERVATIONS

ON

URINARY DEPOSITS.

By R. H. Brett, Esq. M.R.C.S.

[Continued from p. 800.]

Complex Organic Deposits.

Having noticed those deposits which are of a strictly organic nature, and which are to be found among the constituents of healthy urine, I shall now pass on to the consideration of the second division of the first class, and which is made up of those deposits consisting of an organic acid and alkaline, or earthy base, the constituents of which salts are to be found in healthy urine, although not under the same state of combination. This class of deposits differs materially from the free lithic acid just described, both physically as well as chemically. In the first place, they generally occur in much greater abundance than the free lithic acid, sometimes manifesting themselves very quickly,—as soon, indeed, as the urine cools; they do not, however, subside so completely or so speedily to the bottom of the containing vessel as the free lithic acid deposit does, so that the urine in many cases will remain turbid even after hours of repose, possessing an appearance not unlike thin pea-soup. It is to this class of deposits that the pink colouring matter attaches itself exclusively; so constant is this, that it may be assumed as a general rule, that wherever the pink colouring matter is found, there also the lithates will be found to exist. In many cases, however, the colour of these deposits is of a pale fawn, with or without a very slight pink tinge. The decidedly pink-coloured urinary deposits is by no means a rare occurrence, as stated by Dr. Prout; indeed, from the opportunities I have had of examining urinary sediments, during some three or four years, throughout the wards of a large hospital, I should affirm that they constitute by far the majority of urinary deposits. When this class of sediments is separated by filtration from the urine, the mass remaining on the filter assumes more or less of an argillaceous appearance, without being granular, as is observed with the free lithic acid deposit; it is quite smooth to the touch, and the particles composing it being in a state of exceeding fineness, their cohesion is more marked than in the lithic acid deposit. If the mass be washed for a considerable time on the filter, it will be found to lose materially in weight; whereas free lithic acid, as has been before noticed, is not similarly circumstanced. When suffered to dry upon the filter, the whole can be readily removed *en masse*, without the particles of which it is composed being separated. In a great number of the deposits of this class which I have examined, the particles have been found cemented together by means of a delicate filamentous structure, similar in appearance to very fine short hairs; these, by their interlacements, appear to form a sort of net-work, upon which the salts become deposited: by boiling in water, these organic salts are dissolved out, and the filamentous structure becomes more apparent as it is seen suspended through the aqueous fluid. I have once or twice observed the same capilliform substance in deposits consisting exclusively of the earthy phosphates. This circumstance has not been noticed by the majority of those who have treated of the urine or its sediments. M. Magendie, however, in a treatise published by him some years since, On the Causes, Symptoms, and Treatment of Gravel, remarks, cap. ii. p. 8:—"Le plus souvent les graviers sont isolés et sortent successivement. Dans un petit nombres de circonstances, je les ai vus former des espèces de grappes, étant attachés les uns aux antres par des poils." In the instances, however, which he relates, the deposit consisted of small calculi rather than a sediment, properly so called, the portions being most of them as large as a good-sized pin's head, and some of them even considerably larger. M. Magendie further observes, that he has occasionally found this delicate capillaceous structure mixed with phosphate of lime and magnesia, but does not allude to any instances of its occurrence in the organic saline deposits.

When urine containing this form of deposit suspended through it is subjected to heat, it becomes generally completely, though sometimes only partially clear, from the ready solubility of the lithates in the hot fluid; and this will be observed frequently even before

the boiling point is reached. No other deposit met with in the urine exhibits the same phenomenon. It must, however, be observed, that if the deposit be previously dried on a filter, its solubility both in the urine, as also in water, will be considerably diminished. A small quantity of free lithic acid is occasionally mixed up with this form of sediment, which will remain unacted upon by water when the dried deposit is boiled in that fluid, although readily dissolved, together with its accompanying lithates, when heat is applied to urine containing these ingredients in a state of suspension.

When this organic saline deposit is ignited, it blackens, and is in great measure dissipated, yielding an ash of a white colour, and generally of larger bulk than is observed in the case of the free lithic acid. This residue commonly effervesces with acids, and is alkaline in its reaction. Upon further examination it will be found to consist of carbonate of soda, with or without a little carbonate of lime and earthy phosphate. Both the carbonates of soda and lime result from the decomposition of organic salts during ignition, these salts being the urates of soda and lime. Neither of these salts, however, are always present, the deposit sometimes consisting entirely of urate of ammonia, with, perhaps, a trace of earthy phosphate. In those deposits, however, which occur in the urine of gouty subjects, the urate of soda will generally be found to exist in pretty considerable quantities. It not unfrequently happens that if ignition be performed in such a way as to allow of the collection of the products of sublimation, that a portion of muriate of ammonia will be obtained; and this is somewhat remarkable, when we bear in mind the ready solubility of that salt in water. A solution of caustic potass, or soda, is capable of dissolving this class of sediments, with an abundant evolution of ammonia.

From the above statement it is clear that the organic saline sediments are frequently made up of several ingredients, not consisting of one, but of several binary compounds. The following are the salts found by analysis :—

Urate of ammonia.
——— soda.
——— lime.
Muriate of ammonia.
Free lithic acid (in very small quantity.)
Earthy phosphates and alkaline sulphates (mere traces.)
Colouring matter.

This class of sediments has been represented as never acquiring the deep red, or reddish brown colour, of the uncombined lithic acid; it occasionally happens, however, that the lithate deposit is so slightly imbued with colouring matter, as to assume an appearance so closely resembling the earthy phosphates, that mere inspection will not suffice to distinguish between them. In such cases the application of heat to the urine through which the sediment is diffused, will be found sufficient to clear up the difficulty. If the deposit be of the phosphatic kind, no appreciable alteration will follow; if, however, the lithates be present, the turbidity will entirely disappear.

It is not a common circumstance to find, where the deposit of the lithates prevails, much mucus precipitated also; this is, however, occasionally found to be the case, and it happens in such instances that the ordinary character of the lithates is masked by their mixture with the mucus, so as to lead to the idea that the deposit was phosphatic. This was well marked in a specimen of urine which I examined some short time since. The patient from whom it was procured was labouring under symptoms of an affection of the bladder.

The urine was acid in its reaction, and the deposit which took place from it very abundant. A portion of this urine was allowed to remain at rest for some time, and the supernatant fluid, which was still very turbid, poured off from the bulky precipitate occupying the lower part of the vessel. The decanted fluid was left at rest, and the remaining portion, containing the bulky deposit, thrown upon a filter. The filtration went on slowly: the clear fluid which ultimately passed through was found to be highly albuminous; the residue on the filter, when dry, formed a thick varnish, which, when moistened with water, again assumed the pulpy semi-transparent character which it possessed before drying. It contained a minute portion of urate of ammonia, or uric acid, mixed up with it, but mainly consisted of mucus tinged by

the colouring matter of the urine. That portion of turbid urine which had been decanted, yielded, after some time, an abundant deposit of a pale salmon-colour, and which, upon examination, was found to consist chiefly of urate of ammonia, with a portion of pink colouring matter, and a little mucus. This specimen of urine was the more interesting because it was albuminous, a condition of that secretion very rarely met in conjunction with the deposition of the pink-coloured lithates.

Complex Inorganic Sediments.

I now come to speak of the last division of that class of deposits, the constituents of which exist in healthy urine, viz. the combination of an inorganic acid with earthy or alkaline bases. This form of sediment is much less frequently met with than the preceding. The urine from which it takes place is for the most part pale in colour, but not invariably so, as stated by Dr. Prout. I have examined more than one specimen of urine depositing the mixed phosphates, the colour of which was quite equal to that of healthy urine. In such cases, however, the deposits are not generally found to possess the ordinary white colour of the phosphates, but have an appearance in no respect different from that of the very pale lithates. The circumstance of the phosphatic deposits most frequently occurring of a white colour, seems to depend more upon a deficiency of colouring matter in the urine than upon any want of affinity between the earthy salt and the urinary colouring principle.

The sediments in question are generally found in smaller quantities than those consisting of the lithate; it sometimes happens, nevertheless, that the quantity is very considerable; and the appearance of the deposit will frequently be found to differ accordingly as it may occur in larger or smaller proportion. When in small quantity it usually subsides readily to the bottom of the containing vessel, is generally of a white colour, and entirely devoid of crystalline character. When collected upon a filter, washed, and dried, it becomes pulverulent, earthy in appearance, and soft to the feel, and is sometimes found mixed with small hair-like substances, analogous to those observed to cement in some instances the particles of the lithates together. This phenomenon, however, I have observed only when the phosphatic deposits have been coloured.

When, on the other hand, the bulk of the sediment is considerable, it will frequently assume a mucilaginous character; and in some cases is so tenacious as to be without difficulty lengthened out into threads when a stirring rod plunged into it is drawn up along the sides of the vessel. This might lead to the supposition that the deposited mass mainly consisted of mucus; but this is not the case, for when dried upon a filter the whole becomes soft and pulverulent. It must be remembered, however, that mucus is not at all unfrequently associated with the phosphate of lime deposit, and may be separated from the latter by the agency of diluted muriatic or nitric acid, which will dissolve out the earthy salt, leaving the organic matter unacted upon.

These are the physical characters of the phosphate of lime deposit; it remains now to be shewn in what way it may be distinguished from all other urinary sediments by its chemical habitudes.

Tests of the Phosphatic Deposits.

Whenever a white or pale fawn-coloured deposit takes place from the urine, insoluble in caustic potass or soda, and completely soluble in muriatic acid, or nearly so, without effervescence, that deposit is of the phosphatic kind. If, in addition to this, we find that the muriatic acid solution, when treated with just sufficient ammonia to render its reaction only very slightly acid, gives an abundant precipitate with oxalate of ammonia, and the clear fluid separated from the precipitate by filtration is not affected by the addition of caustic ammonia in excess, the salt is exclusively phosphate of lime. If a portion of the dry deposit in question be ignited, it blackens, and yields after a continuance of the heat a white ash, losing, however, very little in weight. This residue is not alkaline in its reaction, and does not effervesce with acids.

These characters, physical and chemical, will be found quite adequate to the distinction of the phosphate of lime from mucus, on the one hand, or the exceedingly pale lithates, on the other.

It has been stated by authors that the urine in this particular form of deposit is always found alkaline; and this alkalescency has been considered as essential to the production of the precipitate; for it is argued that the free phosphoric acid, which held the earthy phosphate in solution, being neutralized, the latter becomes thrown down. That this statement is correct in many, if not in the majority of cases, appears highly probable, more especially when we take into notice the extreme proneness of this description of urine to undergo decomposition, by which large proportions of carbonate of ammonia are formed; but still instances do occur in which, although a deposit of earthy phosphates is formed, the urine is itself, nevertheless, acid in its reaction. This I have observed in more than one instance, especially where the phosphatic salt has been coloured like the palest lithates; also where the precipitate has chiefly consisted of the triple phosphate.

In these cases it is manifest that the deposition of the phosphatic salts cannot depend upon the neutralization of the acid which acted as their solvent, for otherwise there would be found an alkaline, and not an acid, condition of the urine. The following question suggested itself. Is carbonic acid gas the solvent in such cases, and is it by the evolution of this gaseous matter that the earthy salts are deposited? There has, it is true, been much discrepancy of opinion among experimentalists, concerning the existence or non-existence of this acid in healthy urine. The pneumatic experiments of Dr. Marcet would lead us to decide the point in the affirmative; but then the results of the experiments of Berzelius and Woehler, great authorities, seem to negative the assertion. The experiments of Proust and Brande are in favour of its existence, and Dr. Prout considers it highly probable. I shall now proceed to detail some experiments which I have instituted on this subject. I have endeavoured, as it will be seen, to avoid all those sources of fallacy which have been objected to that mode of investigating the matter which I have adopted.

1. About four ounces of healthy urine just passed, and reddening litmus paper, were placed in a glass flask having a long neck. A tube, bent twice at right angles, was then inserted, the free end dipping into lime-water. After a short time, and before active ebullition had commenced, a copious turbidity was produced in the lime-water, gaseous matter continually passing over.

It has been objected to this experiment, that carbonate of ammonia is formed during the process of boiling, and, being carried over, renders the lime-water turbid. The following experiment was then made, in order to test the validity of this objection:—

2. The same quantity of recently-voided healthy urine was treated as in the first experiment; but the free end of the conducting tube, instead of passing into lime-water, was dipped into pure water; in which fluid a portion of litmus and turmeric paper were immersed. After a short time, copious bubbles of gas came over, and after being allowed to pass into the water for more than a quarter of an hour, it was found that the litmus paper was slightly reddened, whereas the turmeric paper was not in the slightest degree altered. It was therefore clear, from this experiment, that no carbonate of ammonia could have passed over, otherwise the turmeric paper would have been reddened.

3. The gaseous matters, instead of being passed into lime-water, or pure water, was collected over mercury in two glass tubes; a piece of caustic potass was passed up into one of the tubes, and after some time it was found that nearly the whole of the gaseous matter had been absorbed. The other tube had lime-water poured into it: after agitation, the lime-water was rendered exceedingly turbid. This experiment was performed in conjunction with my friend Mr. Bird.

I think, then, it may be fairly concluded, from the result of these several experiments, that carbonic acid does exist in healthy urine. It now remains to be shewn by experiment that this acid is capable of acting as a solvent over the urinary earthy phosphatic salts. I have observed myself, and it has often been noticed by others, that, upon applying heat to certain specimens of urine, a deposit has ensued; which, upon examination, has turned out to be phosphate of lime. This has been said to result from the urea undergoing decomposition; and in those cases where the urine is already strongly alkaline, and gives other evidences of a great proneness to undergo decomposition, this explanation may hold good; having, how-

ever, in several instances found the urine yielding the earthy phosphate by boiling, acid both before and after ebullition, I was led to conclude that such a deposit could not result from the decomposition of urea or other organic matter contained in the secretion, unless, indeed, it be supposed that only just enough urea or animal matter had undergone decomposition to yield sufficient ammoniacal salt to neutralize the free phosphoric acid, and no more; a circumstance not in the slightest degree probable, seeing that the ebullition had been continued for some time even after the precipitate had come down.

Is carbonic acid capable of dissolving phosphate of lime by being passed through that salt suspended in water? A very diluted solution of muriate of lime was rendered turbid by the addition of an excess of a solution of phosphate of soda; carbonic acid gas was then passed through this mixture for some time: the whole of the phosphate of lime was ultimately dissolved, the fluid becoming quite clear. The fluid just reddened litmus paper. Upon boiling, the phosphate of lime again came down, the fluid no longer possessing an acid reaction. The precipitate which took place from this fluid was collected, and found to be completely soluble in diluted muriatic acid, without effervescence. It is therefore evident that carbonic acid is capable of dissolving recently precipitated phosphate of lime, and that the evolution of the gas again causes the salt to fall. The same experiments were then tried with the ammoniaco-magnesian phosphate with precisely similar results. The following experiments were then made upon different specimens of urine:—

(A.) A portion of healthy urine, just voided, was rendered slightly alkaline by caustic potass; a deposit took place of the phosphate of lime; a current of carbonic acid was then passed through the mixture; the phosphate of lime was dissolved; the application of heat again caused it to come down: a drop of muriatic acid entirely dissolved it.

(B.) About 4 oz. of urine, obtained from a patient with chorea, was filtered, in order to separate some of the pale lithates which had subsided: the clear fluid was placed in a flask supplied with a conducting tube, as in the experiments before mentioned; the gaseous matters were driven over by heat into lime-water; the urine gave off copious bubbles of gas, which rendered the lime-water turbid, and at the same time the clear urine became turbid, and ultimately let fall a copious deposit, which, when collected, was found to be phosphate of lime. This urine was acid both before and after ebullition.

(C.) Another portion of the same urine was treated in the same way, excepting that the gaseous matters were conducted into pure water, into which litmus and turmeric paper were placed. The gas evolved slightly reddened the former, but did not at all affect the latter.

(D.) Some of this urine, which had been rendered turbid by boiling, was allowed to cool, and then treated with a current of carbonic acid. The whole was rendered clear, becoming again turbid by boiling.

(E.) Some of this urine, rendered turbid by boiling, was filtered. Equal bulks of the filtered fluid and fresh healthy urine were treated with precisely the same proportions of caustic ammonia: the precipitate which ensued from the diseased was afterwards found to be more considerable than that from the healthy urine.

These experiments have been repeated upon several specimens of urine, of a similar character to that just spoken of; the results, with very little differences in the quantity of phosphate of lime precipitated by ammonia, were the same. We may therefore conclude that certain specimens of urine yielding the pale lithates, contain a considerable quantity of phosphate of lime which is held in solution by carbonic acid, and is thrown down by heat, in consequence of the evolution of that gas, and not from the formation of carbonate of ammonia resulting from the decomposition of urea or other animal matter. It may also be concluded, that, in some cases, the quantity of phosphate of lime which remains in solution after the application of heat, is considerably greater than we meet with in healthy urine; and there can be little doubt but that the total quantity of phosphate of lime contained in urine of this description is considerably greater than what we meet with in an equal bulk of healthy urine.

It now remained to institute some experiments upon urine actually depositing the phosphates upon standing. The urine experimented upon was obtained from a patient who voided it

in my presence, at an early hour in the morning; the same individual having passed urine the previous night, which was found exceedingly turbid from the phosphates the next morning, and also in a slight degree alkaline. The morning urine was of specific gravity 1020, tolerably clear, containing in suspension a mucous cloud only: after standing twenty-four hours, the mucous cloud deposited, the supernatant fluid remaining clear; small transparent glistening crystals of the triple phosphate appeared here and there diffused through the urine, some adhering to the sides of the glass vessel and others floating on the surface of the fluid. This urine, be it observed, was distinctly acid when passed, remaining so for twenty-four hours, or more.

1. A portion of this urine, about nine hours after it had been passed, was heated in a flask; the gaseous matters being collected over mercury in two glass tubes, caustic potass was passed up into one, by which means considerable absorption ensued; to the other a little lime-water was added; considerable turbidity was produced by agitation.

2. This urine exerted an acid reaction even after boiling for nearly an hour and a half, and the gaseous matter which came off reddened litmus paper.

3. Two equal bulks of this urine, before any seperation of triple phosphate had taken place, were placed side by side, and through one a current of carbonic acid was passed. After standing for twenty-four hours, a deposition of the phosphatic salt was observed in that specimen which had not been treated with carbonic acid gas, but none in the other.

4. This urine was boiled directly after it was passed; an abundant phosphatic deposit ensued, the fluid still exerting an acid reaction.

5. This urine, twenty-four hours after it had been passed, and after a deposition had taken place, gave off carbonic acid by heat; the gaseous matters, conducted into water, did not redden turmeric paper.

These facts, then, relative to the presence of carbonic acid in urine, and the solvent power it possesses over the earthy phosphates, being established, serve to explain the otherwise anomalous circumstance of the phosphate of lime being occasionally precipitated from the urine by the mere agency of heat, without the necessary decomposition of any organic matter capable of yielding an ammoniacal salt; and also invalidates the statement that an alkaline condition of the urine is always co-existent with the deposition of the phosphatic salt. It is, however, maintained, that even in those cases where the urine depositing the phosphates remains acid for some time, that all the phosphatic deposition which may ultimately take place is depending solely upon the evolution of carbonic acid; for urine of this description is prone to undergo decomposition, by which means ammonia is formed, which will, by neutralizing all the free acids existing in the urine, cause a further precipitate of the phosphates; for all these latter salts, it must be remembered, cannot be separated from such urine by mere boiling; for after that process has been completed, the clear filtered urine will always yield a larger or smaller proportion of the earthy salts by the addition of ammonia; but so long as the urine remains acid, there can be no doubt but that the deposit results from the escape of carbonic acid. Whether the carbonic acid, in these cases, is separated from the blood in the kidneys, or is secreted in the bladder or urinary canals, is a matter of uncertainty. I should incline, however, to the latter opinion, from analogous reasoning with respect to the known functions of the stomach and intestinal tube; for it is an acknowledged fact that carbonic acid is secreted in those cavities: thus Chevreul found, in the stomach of a man just executed, 14 per cent. of carbonic acid, besides other gaseous matters. We may therefore, I think, fairly conclude, that in cases of the phosphatic deposits, the urine may be either alkaline or acid, most frequently perhaps in the former condition even when just voided; that when the secretion is alkaline from the first, it is highly probable that great proneness to decomposition exists, so that a very short delay of the secretion in the bladder will suffice for producing this change in it; that whenever the urine in such cases is turbid at the moment of its emission, it will be found alkaline. In those cases where the phosphates are thrown down, the urine remaining acid, it will generally be found clear when passed; or if opa-

lescent, from suspended mucus, carbonic acid in considerable quantities will, I believe, be always found to be present; that so long as the urine continues acid, the deposit is entirely owing to the escape of carbonic acid; and although such urine ultimately becomes alkaline, by which means a further quantity of the phosphates become separated, still that it is much less prone to undergo decomposition than in the cases where it is found alkaline from the first. It is not improbable either, that in these particular cases the phosphatic salts are secreted in the kidney, without a corresponding proportion of free phosphoric acid to hold them in solution; that they pass suspended in the urine into the bladder, and there become dissolved by the carbonic acid secreted in the cavity of that viscus.

The inferences I have drawn from the foregoing experiments, seem to be borne out, to a certain extent, by the effects which have been observed to result from the administration of certain mineral waters in cases of phosphatic disease. Thus Magendie, in his work on Calculous Disorders, before cited, speaks of the advantage accruing to individuals suffering from the *gravelle blanche*, as he denominates it, from the employment of the waters of Seltz, Contrexeville, Bains, and Victry. Now all these waters contain considerable quantities of carbonic acid, besides certain alkaline and earthy carbonates: according to Berzelius, the quantity of carbonic acid in the Seltz water is equal to its own volume. Now, as neither the carbonated or bi-carbonated alkalies exert any solvent action over phosphate of lime, and as free carbonic acid has been proved, by direct experiment, capable of dissolving it, I conceive that the beneficial results which have been obtained from the use of the waters in question were mainly attributable to the agency of the large quantity of carbonic acid gas contained in them. It would not therefore be injudicious, perhaps, to employ water highly charged with carbonic acid, in those cases of the phosphatic deposit where the mineral acids had either failed in their action, or their administration was not deemed advisable.

Ammoniaco-magnesian Phosphate.

I shall now conclude what I have to say respecting those deposits the constituents of which are to be found in healthy urine, by a brief notice of that combination of an inorganic acid with an earthy and alkaline base, called the ammoniaco-magnesian phosphate, and a few words on the carbonate of lime deposit. The triple compound of phosphoric acid, magnesia, and ammonia, very rarely occurs as a pure uncombined sediment, nor is it ever found *per se* in urinary calculi. Doubtless in all cases where the sediment possesses a marked crystalline form, it mainly consists of the triple salt, to which, indeed, it owes its crystalline structure; but at the same time larger or smaller quantities of phosphate of lime will be found to be present, upon applying the proper tests for detecting the presence of that salt. Depositions of the triple phosphate, the particles of which are sufficiently finely divided to constitute what is commonly understood by the term urinary sediment, are by no means common. Magendie observes, "Je n'ai jamais rencontré cette espèce de gravelle que sous l'etat de graviers plus ou moins volumineux; dans certains cas lisse à leur surface, et approchant de la forme d'olive ou de pistache." This peculiar salt most commonly separates from the urine in the form of a thin film, which floats at first upon the surface of the urine, but which gradually increasing in density by fresh additions to its bulk, falls to the bottom of the fluid, and is not unfrequently found adhering to the sides of the containing vessel in the form of small white transparent glistening crystals, which are never found tinged with the colouring matter of the urine, which circumstance would serve to distinguish them from the crystalline deposit of lithic acid, which, as I have already had occasion to observe, is always more or less imbued with the reddish brown colouring matter of the urine; neither does this form of sediment ever become associated with the pink colouring matter of the urine. It sometimes happens that deposits mainly consisting of the triple salt, do not appear to possess any crystalline structure until after they have been collected on a filter and dried, when the crystalline character is readily recognized, especially by the aid of a lens.

If the delicate pellicle which forms on the surface of urine yielding deposits of the triple salt be placed on a filter, washed, and dried, the quantity is found

to be so inconsiderable that you can scarcely, and in some cases cannot at all, observe its characteristic crystalline structure, in consequence of its having been imbibed by the tissue of the bibulous paper: the better plan in such a case is to employ acetic, or very diluted muriatic acid, for the last washings, which should be afterwards examined as follows:—

Evaporate the acidulous solution of the triple phosphate to a few drops; place the fluid on a glass plate, in the field of a microscope of ordinary power; take a glass rod charged with a drop or two of a solution of caustic ammonia, and immerse the end in the acid fluid. After a short time numerous crystals of the triple phosphate will be observed to deposit, observing somewhat of a stellated arrangement, each crystal being a prism: this is exceedingly characteristic of the salt in question. This microscopic mode of proving the existence of the triple phosphate was, I believe, first introduced by Wollaston. Dr. Yelloly has also employed it very successfully in the analysis of calculi containing portions of the triple salt. The crystalline film just spoken of will, I believe, invariably be found to consist of the pure ammoniaco-magnesian phosphate, without any admixture with phosphate of lime. Not so, however, the deposit found at the bottom of the containing vessel; this, I believe, always contains a small proportion of phosphate of lime; for when the muriatic acid solution of it is barely neutralized with ammonia, oxalate of ammonia always causes a turbidity, indicating the presence of lime.

Those remarks which have already been made relative to the action of carbonic acid on phosphate of lime, will apply equally well to the triple salt just considered, as determined by experiment.

Carbonate of Lime.

I believe there are no cases on record in which the carbonate of lime has been found, in the human subject at least, assuming the character of a pulverulent amorphous deposit; it has been observed, and that only in a very few instances, in the form of small calculous concretions, of a convenient form and size to admit of their egress by the urinary channels. Urine that has been long kept, and undergone more or less of decomposition, has been observed by Proust, the Spanish chemist, to yield small crystals of carbonate of lime, which were found adhering to the surface of the containing vessels; they most probably resulted from the decomposition of urate of lime, which exists in healthy urine. I once had an opportunity of examining a urinary human calculus, of the size of a small hen's egg, the external crust of which consisted of carbonate of lime. This salt is readily enough distinguished from all other urinary saline compounds, by its white colour, solubility in weak acids, such as the acetic or diluted muriatic acid, with effervescence; and its copious precipitation from its acid solutions by means of oxalate of ammonia, the acid fluid being previously neutralized by ammonia.

[To be continued.]

CASE OF ANEURISMAL TUMOR IN THE ORBIT,

FOR WHICH THE COMMON CAROTID ARTERY WAS TIED.

To the Editor of the Medical Gazette.

Sir,

I should feel obliged by the insertion of the following case in your journal: if not too long, I think you will consider it sufficiently interesting. For the sake of brevity, having omitted almost all details of treatment, (as I am not aware that it differed from that usually pursued in similar cases,) and having confined myself to an account of only the principal occurrences, I am not aware that the history could be advantageously curtailed.

I have the honour to be, sir,
Your obedient servant,
George Busk,
Surgeon to the Seamen's Hospital.

S. H. S. Dreadnought,
Feb. 19, 1836.

Richard Simmons, aged 20, a seaman, was admitted July 13, 1835, labouring under the usual symptoms of concussion of the brain, with very considerable hæmorrhage from the right ear, and a small wound behind the left. It was stated that he had received a severe blow on the right side of the

head, from the gaff of the vessel to which he belonged, by which he was rendered immediately insensible; and he was nearly so on admission, but could with difficulty be roused. At first he was very pale and cold, but in an hour or two rallied. The hæmorrhage from the right ear continued all night. The following day he was quite sensible, but appeared dull, not complaining of any pain. Pupils natural.

On the 15th he was still dull, and completely deaf in the right ear; the eye-lids and integuments around the left orbit were swollen, apparently from serous effusion; they were not discoloured or painful. The pupil of the left eye was dilated and fixed; vision, however, was unimpaired, but he was unable to move the globe of the eye in any direction, and had slight paralysis of the facial muscles on the left side.

On the 18th, some increase of inflammatory symptoms required attention, but was readily subdued. The pupil was observed to have become irregular, the irregularity consisting in an elongation downwards, and vision was not quite clear; there was occasionally a very partial rotatory movement of the globe, as if caused by the apparently involuntary action of the superior oblique muscle. He had some headache, confined principally to the left side. On the 21st his mouth became slightly affected by mercury. On the 24th, the headache was very trifling, but the left side of the face had become numb, and felt very "uncomfortable," and he complained of great dryness in the mouth, although his tongue was quite moist; there was also considerable purulent discharge from the right ear. On the 25th, the integuments of the left side of the face and head extending to the vertex, were extremely tender to the touch, but without any morbid appearance. The paralysis continued unaltered. On the 28th, the conjunctiva of the left eye was much inflamed and swollen from œdematous effusion; and on the 31st, purulent matter was deposited between the laminæ of the cornea, at the lower part, with nebular opacity, but the eye was much less painful, and headache gone. His health was now in most respects restored, and functions properly performed.

He began soon to complain of curious noises in the right ear, from which the discharge continued, and he was very deaf. The eye was not painful, but the onyx was increased. In the beginning of September the paralysis and loss of sensibility were complete. The anterior laminæ of the cornea had given way, and a deep ulcer occupied the site of the abscess, of a healthy character. No change of importance took place until about the 20th of November, when he became affected with small-pox, and was sent to the Small-pox Hospital, whence he returned on the 1st of December. On his re-admission, the state of the face was unaltered; the eye generally was prominent, and much inflamed; the ulcer on the cornea was very large, and in an irritable state. The severity of these symptoms was soon pretty well subdued; and attempts were made, by counter-irritation in every form, and other means, to remove the palsy of the face, but without effect. Sensibility in some measure returned, preceded by anomalous painful feelings in the affected integuments. He continued in this state, without any change in symptoms or appearance, except that the eye seemed to protrude rather more from the orbit than had been previously observed. The ulcer on the cornea filled up. His general health being quite restored, and medical treatment not appearing to have any effect on the local complaint, he was desirous and recommended to go to his friends in the country, and trust to the efforts of nature.

However, on the 1st of February, on making examination of the eye, I felt on pressing the globe a distinct pulsation; and farther found, deeply situated in the upper and inner part of the orbit, a firm pulsating tumor, which appeared about half an inch in its transverse and longest diameter: it was situated between the levator of the eyelid and the bone, and did not show itself externally, but when the eyelid was raised it caused some projection of the loose conjunctiva.

The pulsation of the tumor was accompanied with a very distinct whirr, which could also be felt on pressing the parts in its immediate neighbourhood. Through the stethoscope, a very loud aneurismal whizzing sound was communicated, which could also be heard on applying the instrument over the inner canthus of the other eye, and on

the left side of the frontal bone, as high as the roots of the hair, and nearly as far back as the ear.

He has very loud noises in the head, in the right ear, resembling the sound of church-bells, and in the left like the breaking of waves on the sea-shore; he complains more of these incessant noises than of anything else. The eye feels hot and uneasy, but otherwise he has no pain.

As pressure on the left common carotid put a stop to the pulsation and sounds of the aneurism, and to the noises in his head, it appeared to me that a ligature on that vessel presented hopes, and perhaps the only hope, of affording him relief, or even permanent cure. As a preparatory step, and he being very well able to afford the loss, 20 ounces of blood were taken in the evening, and the next day, Feb. 2nd, the left common carobid was tied: immediately on tightening the ligature, the pulsation and sounds of the aneurism ceased, as also the internal noises. In the evening, four hours after the operation, obscure pulsation could be felt in the tumor, which, however, was not large. The whizzing sound could also be plainly heard with the stethoscope, and over as large an extent. There was no pulsation in the temporal artery; the internal noises were at intervals nearly as loud as before the artery was tied, and at others, nearly absent; he felt great pain on swallowing; pulse 110. He took ℥ss. of liq. opii sedativus, and a wetted cloth was applied to the forehead and eye. On the 3rd, in the morning, the pulsation was very obscure, and the sounds much diminished; the interval noises were also much less. He had had no sleep, and complained much of pain on deglutition and on coughing, and of severe pain in the left hypochondrium. He has also a troublesome cough, which he has had for some time; pulse 120, sharpish. He was bled to 16 oz., with immediate relief, and in the evening was much easier in all respects. On the 4th, no remains of the tumor could be felt, and all pulsation was gone from the orbits, nor could any sound be heard with the stethoscope. The internal noises are quite absent, and his hearing somewhat improved; pulse 100, soft; skin moist, and tongue clean. The pain had left the left hypochondrium, but he felt some in the right, when coughing. The wound was dressed, and the sutures removed; union had taken place to a great extent. In the evening the cough was occasionally severe, with mucous expectoration, and pain referred to the diaphragm; pulse 120, soft; skin moist; bowels not opened. He had some calomel and compound ext. of colocynth, and a mixture with sulphate of magnesia and tincture of digitalis, and a linctus for the cough.

5th. He felt very comfortable; has had several stools; countenance pale; pulse 100; eye less prominent.

6th. Feels weak, but is quite free from pain; cough nearly gone. The conjunctiva much less vascular than before the operation, and the cornea is clearer; some grumous blood was discharged from the left nostril in the night; pulse 90.

7th. Pulse 80; the lips of the wound are opened, but it is filled with healthy granulations; sleeps well; appetite too good.

11th. He sat up several hours, and on the 15th the ligature came away.

18th. The wound is all but cicatrized; he is quite free from pain or uneasiness, and feels only hungry and weak; he is not yet allowed meat; pulse 70, soft. No remains of the aneurism can be detected; the eye has returned wholly to its natural level. The upper half of the cornea is quite clear, the lower occupied by a dense leucoma, to the centre of which runs a large red vessel from the conjunctiva; that membrane is hardly vascular, and vision is good through the clear part of the cornea, when the lid is elevated; the pupil natural.

The left side of the face is quite paralyzed, but sensibility is perfect, except on the left side of the nose, where he feels pricking pains when touched. He has no power of motion whatever over the globe of the eye, and is still very deaf, and more so in the left ear than in the right, but has no noise in the head. His intellects have never been affected. Pulsation is very distinct behind the lower portion of the sterno-cleido-mastoid muscle, probably in the subclavian.

If any change of consequence takes place while the man is under my care, I will take the liberty of communicating it through your publication.

CASE OF RUPTURE OF THE UTERUS,

FOLLOWED BY COMPLETE RECOVERY.

To the Editor of the Medical Gazette.

Sir,

I beg leave to lay the following case before the profession, through the medium of your journal.

I was sent for to Mrs. Rook, aged 28, a strong healthy woman, in labour of her third child, on the 1st November, 1834, at seven A.M. I had gone to a distance a short time previously, and did not return till nine o'clock. I found her in very severe labour, the breech presenting at the external orifice. The membranes had given way at the time I was sent for, and the labour was described as having been severe from six o'clock. The breech was expelled in a few minutes; the pains all the while most violent, and continued until the child had passed as far as the umbilicus, when they suddenly ceased, and the patient became pale, and vomited several times. Considering these symptoms as merely the effects of exhaustion, I desired her to have some spirits and water; which in some degree revived her. After waiting several minutes for a return of the pains, the child became convulsed. Afraid it might be lost, I determined to force the delivery. I had not proceeded long when the propulsive action returned, but now so weak that I was compelled to use all the force I could consistently with the safety of the child. When the delivery was accomplished the woman was quite exhausted, which I attributed to the severity of the labour. Having ascertained that there was no unusual discharge, I began to use the necessary means for the restoration of the child, in which I might be occupied about ten minutes. When I laid hold of the cord I felt a twitching, which induced me to think there was another child; and on applying my hand to the abdomen for the purpose of ascertaining, I was confirmed in the belief, by finding the epigastric region enormously distended. On pressing firmly, in order to satisfy myself, I was somewhat surprised to find the tumor give way suddenly under my hand. Now convinced there was no child, I began to suspect the existence of hour-glass contraction. The twitching still continued in the cord, and as the discharge was considerable, and the woman becoming faint, I gave her sixty drops of laudanum, preparatory to introducing the hand. I had considerable difficulty in overcoming the contraction, and it was not till upwards of a quarter of an hour had expired that this was effected. The uterus was quite flaccid beyond the point of contraction. I found the placenta in the right lateral, and inclining to the anterior, region of the uterus, firmly adherent. Tracing it to the fundus, what was my horror on getting among the intestines! My very blood ran cold, and I felt as if I had been guilty of murder. On directing the finger forward, I felt the peritoneal lining of the abdomen. When withdrawing my hand, I pushed the intestines up clear of the lacerated edges of the uterus, and then endeavoured to separate the placenta by scratching it with the nail. Finding this in vain, I resolved to break it down, and bring as much of it away as possible, that the uterus might be allowed to collapse. I succeeded in removing about a third of it, when the woman became so faint as to oblige me to desist from all further attempts. The discharge being considerable, I determined, as a forlorn hope, to plug the vagina, so as to prevent the external discharge, and thereby encourage the formation of a coagulum: fearful, at the same time, that I was only avoiding one evil to incur another—its escape into the abdomen.

Cordials were now freely administered, as the patient was apparently in a sinking state, and I informed her attendants of the nature of the case, telling them I had no hope of her recovery. She was seized with faintings several times during the day. On the following morning I removed the plug, and in the course of the day I requested Mr. Blackburn to see the case. He urged me to endeavour to remove the remainder of the placenta: in the evening I removed one or two small pieces with the finger, which were lying loose in the upper part of the vagina; but she complained so much of tenderness that I did not venture to introduce the hand. The abdomen was somewhat tender and swollen, so that she could no longer bear the bandage, which was accordingly removed.

On the evening of the 3d (Mr. Blackburn being still anxious for the removal of the placenta), I requested him to make the attempt. He introduced the hand into the vagina, and laid hold of what he thought was a part of the membranes: on pulling it down, it was followed by a portion of the intestine. After having examined it, the membrane which was gangrenous was cut off, and the intestine returned as speedily as possible. We now gave the woman up for lost, not conceiving there was the slightest possibility of her recovery.

She continued very low from the time of delivery. Pulse from 120 to 150, small, thready, and compressible. On the fourth day she was seized with vomiting of a dark-coloured fluid, resembling coffee-grounds. Abdomen much distended, and tender on pressure; notwithstanding which, the wine, and occasionally brandy, was continued, as the patient appeared to be sinking. The opiates were omitted and castor-oil administered, the bowels not having been moved from the first. We now concluded that there must be strangulation of the intestine. Dr. Carson was called in at this time, at the request of the husband: he cordially agreed in the treatment pursued, and advised its continuance. The bowels were freely moved in the evening, but the vomiting did not cease until early the following morning—about sixteen hours from its commencement. She went on to improve for three days—treatment, wine, beef-tea, soups, and opiates at bed-time—when the vomiting again returned, and lasted for ten hours, though not so severe as on the former occasion, and the bowels were severely purged; for which opiates were given. After this she improved rapidly, and began to take a little food; the pulse becoming stronger and less frequent, and the bowels regular.

From the second day there was a dark grumous discharge from the vagina, extremely offensive, with portions of membrane occasionally: it afterwards became whitish, and of the consistence of cream, and continued till the 17th December. She was able to leave her bed in three weeks, and went on improving without any untoward symptom.

I have frequently seen this patient since, and though she is not so stout as formerly, yet she enjoys the most perfect health. She has not since menstruated, but she is still suckling the child.

I am not certain how far I was justified in breaking down the placenta; yet it must have had the effect of causing its separation in a shorter period than otherwise would have happened: but, on the other hand, I was thereby incurring the risk of increasing the hæmorrhage.

The patient was a woman of a most robust constitution, and to this alone must her recovery be attributed. She entertained the most sanguine hopes of recovery herself, and, in spite of every remonstrance, she persevered in suckling the child, although there was little or no secretion of milk until about a week after delivery.

I cannot exactly say what was the extent of the rupture in the uterus: so far as I was able to judge, I should state it to have been at the least eight or nine inches.

For about two months previous to her confinement, she was affected with a pain in the right iliac region, which was occasioned by a fall. I am inclined to think that the excitement consequent on the injury may have occasioned so intimate a union between the substances of the uterus and placenta, as to prevent the free contraction of the uterus in the part occupied by the placenta; so that one part being weaker, and contracting more, than the other, occasioned the rupture. This is at least probable, from the circumstance that the one side of the rent was bounded by the margin of the placenta.—I am, sir,

Your most obedient servant,

John Stuart Currie,
Surgeon.

Edgehill, Liverpool,
Feb. 7, 1836.

CHEMICAL ANALYSIS OF HOMŒOPATHIC POWDER.

To the Editor of the Medical Gazette.

Sir,

I do not pretend to fathom the philosophic depths of the homœopathic system of healing, but I can deal with its facts. I lately got possession, on the point of a pen-knife, of a small portion of one of its mysterious powders, which contained altogether as much as would lie on a shilling, and was to be the sole medi-

cine for four days; and I submitted this quantity to a microscopic investigation. The result at which I arrived may be judged of by others, when they know the several processes of my analysis. My stock was not great, and you may readily conceive, that for a variety of experiments, I had to husband it carefully.

In the first place, to a very minute portion of it, I exhibited ni ric acid; the whole of the mass gradually broke down and dissolved into a colourless mucilage. To this I applied ammonia; and the substance being spread very thinly over a plate of glass, on spontaneous evaporation it crystallized readily in long flat prisms. I was led at once to conjecture from these two results, that the substance was no active mineral, but that it was probably of the nature of sugar, and that I had obtained in the first place oxalic acid, and in the second the prisms of the oxalate of ammonia.

I tried several other processes, which need not be detailed: but on adding a portion of it to a drop of bichromate of potash, I found that a part of it dissolved into a colourless fluid, in which the bichromate floated in small flat drops, each of these drops containing, floating within it, a number of the oval molecules of starch, and that these in evaporation entirely prevented the otherwise ready crystallization of the bichromate.

I then spread a portion of the powder on a glass, and breathed on it. The moisture immediately swelled the oval particles, and it assumed all the character of starch wetted with warm water, the particles, however, being occasionally agglutinated by another amorphous substance. On applying iodine, the particles assumed a dark colour.

Again, I dissolved some of the powder in sulphuric acid, which occurred with a slight evolution of gas. On adding hydriodate of potash, the iodine was disengaged, and thrown down, and the molecules appeared of a dark iodine tinge.

I then took a portion of the moistened powder, and added nitric acid, and watching the action narrowly, I observed that it swelled still larger, and burst successively the starch molecules, the same as it does in common starch, only that the substance of these appeared more delicate, and made less resistance. Ammonia had the same effect.

Lastly, I held a small quantity on a glass over a spirit-lamp. It melted at a moderate heat, turned transparent, and yellow, and then brown, and smelt a sort of mixed smell of burnt flour and sugar.

From all these facts I am disposed to conclude that this powerful specific, which is to be administered in infinite small doses, is a compound of sugar and starch, obtained from some delicate vegetables. Had there been any active mineral principle, it must have appeared; and if this is the case, then the mystery of homœopathy does not lie in the medical treatment, but in some recondite arcana yet to be discovered.

I am, &c.

E. C.

[The party, a distinguished surgeon, by whom the above was sent to us, is satisfied that the accuracy of the writer may be depended upon.—Ed. Gaz.]

ON THE PUNISHMENT OF THE GUILLOTINE.

Various opinions have been entertained, nor has controversy yet ceased, touching the question—whether a person decapitated by the guillotine suffers pain for any length of time? In his work, "*Sur l'Incertitude des Signes de la Mort*," M. Julia de Fontanelle has given a summary of the arguments urged by those who support the affirmative side, and adds his own impressions on the subject, to the effect that there *is* decidedly pain subsequent to the act of decollation. When the Convention, in 1792, adopted the guillotine in lieu of the gallows, and were moved to the change perhaps principally by the convenience it offered for inflicting death rapidly, the motives of those who recommended it to their adoption, were humane. Guillotin,* Cabanis, Petit, and other

* Dr. Guillotin died in 1814; he never ceased to lament that his name had become inseparably connected with an instrument of so many horrors. He had perhaps the more reason to regret this, inasmuch as, it is said, nobody ever was despatched by the machine proprosed by him: the *Guillotine*, properly so called, had its edge placed horizontally. It was Louis who suggested its actual and most efficient form, with the edge oblique, whence the *Louisine* would be its more appropriate appellation: but it was too late—the people had already got hold of its first name.

eminent physiologists of the day, bore testimony to the value of the instrument, as one that was well fitted for putting the victim at once out of pain. But Sue, Soemmering, and Mojon, among others, maintained the reverse.

Professor Sue reasoned chiefly from analogy. He struck off the heads of fowls, sheep, and calves, and observed that there were in every instance marked indications of sensibility. In a turkey which he decapitated, the movements of the head continued for a minute and a half; the mandibles and the pupil displayed strong action, and the eyelids winked. The body, after remaining motionless for a minute, rose, stood in the natural position for a minute and a half, walked, shook its wings, put up its foot to scratch its neck, then fell into convulsions and died. All this occupied six minutes, nor did the heart even then totally cease to beat.

In the head of a decollated calf, there was no cessation of movement of the eye-lids, pupils, ears, nostrils, muscles of the face and lips, for above six minutes; and the body moved for seven. The whole expression of the animal indicated intense suffering.

M. Mojon, of Genoa, made some experiments at Paris in the year 1804, in conjunction with MM. Guillotin, Nauche, and Aldini: they obtained the heads of some persons who had just been guillotined, and the following facts were observed:—That for a quarter of an hour the eyes were sensible to strong light; the eye-lids, on being raised, were spontaneously and hastily closed again. That the tongue, on being pricked with a needle, was immediately drawn into the mouth again, and the features betrayed signs of pain; and lastly, that the ear also was sensible to sounds. M. Julia de Fontanelle adds, in confirmation of this last circumstance, that he recollects having seen the head of a man that had been guillotined, on being called by name, *Tillier*, or *Detillier*, turn its eyes to the quarter whence the voice proceeded; nor does he think the story so very improbable, that the head of Charlotte Corday blushed with indignation when the executioner handled it roughly on holding it up to the crowd!

M. Castel, also, in an able paper *On Sensibility*, in one of the journals, says he has no hesitation in believing that the head, immediately after decollation, still possesses the sense of sight and of hearing, as well as the perception of pain.

What M. Julia de Fontanelle states as his final opinion on the subject, is couched in these terms:—"Decapitation is a most cruel mode of death, inasmuch as both head and body suffer *incomprehensible* pain for some time after the blow; the head more particularly, as it is more pre-eminently the seat of pain, paying dearly in this respect, as Petit says, for its prerogative of lodging the great organ of feeling. If every violent change of the organic functions is painful, *à fortiori* the separation of the head from the trunk must be so. It is a dreadful punishment; the circumstances are terrible. * * * * * In short, death by the guillotine is one of the most appalling, cruel, and torturing methods of taking away life: the feeling of pain, I am persuaded, continues for a considerable time, nor is sensation completely extinct as long as the vital heat remains."

On the other hand, some able remarks have been recently made by M. Dubois d'Amiens, which throw discredit on the observations and tenets of his predecessors—as already quoted. He shows the fallacy of some of the physiological arguments adduced by MM. Mojon, Sue, and Fontenelle, and maintains stoutly that sensation in the individual is annihilated on the fall of the knife. "It was noticed," he says, "by M. Mojon, that the blood does not immediately forsake the vessels of the head on decapitation,—a fact, by the way, not much known to painters, who always depict the head as streaming with blood when newly cut off from the body. For the first seven, eight, or ten minutes, there is no flow of blood from the cerebral vessels; but after that period the parts become relaxed, and hæmorrhage ensues. There may be convulsive movements during this time in the muscles of the face and eyes; and these movements may be influenced by stimulants; but it is wrong to infer that these convulsions betoken pain. Such reasoning is deceptive: the circumstances which take place in certain diseases, and in experiments on living animals, prove that it is far from trustworthy. In convulsions, for example, it is well known that the more violent

the paroxysm, the less the pain. The patients, however they may be exhausted afterwards—however they may suffer from lacerations of the tongue, or bruises received in the fit—have felt no pain: the centre of sensation was neither conscious of the internal acts of the organism, nor of the barbarous treatment but too often employed in these attacks. *Clonic* convulsions, it is well known, besides being wholly uncontrolled by the powers of volition, take place without any perception on the part of the individual; while *tonic* convulsions, and those that occur in tetanus, and from poisoning with nux vomica, upas tienté, the bites of rabid animals or rattle-snakes, are undoubtedly painful, but it is because the sensitive centre is uninjured. There is, in short, no analogy between these phenomena and those which are observed on the removal of the head from the trunk.

"The assertion that pain must be felt when the muscles of the face are seen to be convulsed, is no more physiologically true, than to assert that there is no pain when the features are destitute of expression, and the muscles all in a state of repose; for experience shows that the fact is just the reverse. There are disorders in which the frame is wholly unmoved, and yet the pain felt is agonizing beyond conception. We are told by M. Orfila, that when he laboured under cholera, he was for twelve hours pulseless, voiceless, motionless, blue, and icy cold; yet all this time he was a prey to the most dreadful torture: he felt as if pain darted out from every point of the spinal marrow, towards the surface, and then became concentrated in the region of the stomach.

"In the punishment of the guillotine, the instantaneous division of the integuments, the muscles, the vessels, and every part surrounding the spinal marrow, must prevent the occurrence of pain, the whole being done with such rapidity. But the division of the spinal marrow itself—is this attended with pain? The fact seems to be, that it occasions at the instant such a disturbance (*perturbation*) in the sensitive centre, that the functions of the latter cease immediately.

"It may happen, however,—at least there are some probabilities in favour of the supposition,—that the brain does feel for a few instants, but its sensations can only be those of violent disturbance. The brain continues to live as long as it is visited by arterial blood: when that fluid ceases to circulate through it, death ensues—but not instantaneously—particularly as we have seen that the heads of the guillotined retain their blood for several minutes. But is it reasonable to suppose that a head, under such circumstances, should be sensible of painful affections? An energetic stimulant will no doubt augment the intensity of a convulsive movement: a muscle taken from the body may be excited by certain stimuli; yet all this by no means warrants us in believing that the decapitated feel pain."

On these remarks of M. Dubois d'Amiens, which were first published in M. J. de Fontenelle's work, the author makes a few observations by way of reply. He objects to the argument which assumes the unconsciousness of epileptics during a paroxysm. "Though the patients," says M. Julia de Fontenelle, "may assure us they felt nothing, are we to credit the fact? or should we not rather conclude that the sensations they experienced left them no power of recollection—no traces in their memory? Take the instance of somnambulists: they reply to your questions during sleep; yet, on awaking, not only remember nothing, but positively deny that they had a conversation with any one. May not also that exhaustion, which M. Dubois admits, be the effect of overstrained sensation in consequence of the pain suffered during the paroxysm? The want of memory is no proof that there is no suffering during convulsions.

"With regard to the expression of the features, which M. Dubois considers as merely the effects of convulsive action of the muscles, how happens it that *pain alone* is invariably indicated, and that that expression is heightened in proportion to the stimulus applied. *The head of a guillotined man was never observed to look merry, to smile, or even to remain placid.*

"Soemmering, Mojon, Sue, and others, who believe that the heads of persons decapitated by the guillotine are sensible for several minutes, found that belief not only on the fact of the expression of pain so distinctly marked on the face, but on that of the sudden closing of the eyes when turned to the rays of

the sun, a circumstance which has often been noticed. It may be said that this is the mere effect of the stimulus of light on the muscles of the eye; but if so, why is not the same phenomenon observed in all other cases after death? Because in the guillotined the luminous rays stimulate the retina *still alive*, and this excites the reaction of the eyelids; but nothing of the sort can happen to *dead* eyes.

"In conclusion," says M. de Fontanelle, "it is generally admitted that life is the result of organization; that the brain is the centre of sensation; that the head of a guillotined person maintains for some minutes its proper condition and structure—that is to say, all the elements and conditions that belong to it while alive: why, then, should we deny it, during this short space of its organic integrity, the sensitive faculty which is the attribute of that state*?"

REPORT OF A PAPER
ON THE DEATHS
OF SOME
EMINENT PHILOSOPHERS OF MODERN TIMES.

Delivered at the College of Physicians, Feb. 22,

BY SIR H. HALFORD, BART.

AFTER some introductory observations, in the course of which he alluded to the great number of persons distinguished for their intellectual acquirements who had borne testimony to the truth of christianity, the learned author of the paper proceeded to remark, that he might have selected his examples from amid a host of divines, but preferred the spontaneous declarations of other philosophers, whose evidence might, perhaps, be received with greater readiness, as their opinions were not open to the suspicion of being in any degree biassed by a sense of professional duty. He then continued—

LORD BACON, in the indulgence of his fancy, conceived a notion, whilst taking an airing in the winter, that snow would preserve animal matter from corruption; and bought a hen with which he might make the experiment immediately. As soon as the fowl had been disentrailed, he filled it with snow, and deposited it in a large snow-ball. By this operation he was chilled, but nevertheless continued his airing, until he became so ill as to be obliged to stop at the house of Lord Arundel, at Highgate, where he desired to be put to bed. He died of an inflammation of the lungs there, in a week afterwards, in the 66th year of his age.

It may be presumed that the state of his mind gave the disease a great advantage over him. The degradation which he had suffered by the King and Parliament, I dare not say unjustly, though I cannot conceive that his morality was of that Spartan kind, which made the crime consist in allowing it to be detected; or of that Venetian character, in later days, whose best conscience was, according to the poet, not to leave undone—but to keep unknown. But the humiliation had broken his spirit; and although his punishment had been remitted by the same authorities, no doubt that such dilapidation of frame as care and sleepless nights were sure to give rise to, facilitated that dissolution which might not, otherwise, have taken place for years.

To the learning and philosophy of Lord Bacon his posterity has done ample justice. The reasoning by induction, first and exclusively propounded by him as applicable to natural philosophy, is now the only mode of reasoning held to be legitimate in physics; and his writings abound so much in imagery and good sense, as well as knowledge, that it is difficult to lay down the book when once one has taken it up. His disquisitions upon ecclesiastical polity are so luminous and just, and his proposals for simplifying the law so intelligible and practical, that if we may judge by what has lately been done by the wisdom of Parliament, they must have furnished the model for its recent improvements. But his piety is poured forth in such strains of simplicity and beauty, that I must quote one specimen of it, from an address which he was accustomed to utter in his devotions:—

"I have delighted in the brightness of thy sanctuary; thy creatures have been my books, but thy scriptures much more. I have sought thee in the courts,

---

* Recherches Medico-legales sur l'Incertitude des Signes de la Mort, les Dangers des Inhumations precipitées, &c. Par M. Julia de Fontanelle, Professeur de Chimie Médicale, &c. Paris.

fields, and gardens, but I have found thee in thy temples."

To Lord Bacon's genius succeeded a kindred spirit, the ornament and glory of his age, the Honourable Robert Boyle, who was born on the day on which Lord Bacon died. He was of a very delicate habit, and so pale and thin as made it appear wonderful to his friends of the Royal Society, then lately established, that he was able to occupy himself, so laboriously as he did, in making the numerous experiments which were required in his investigations. Nevertheless he lived to 65 years of age, and died exhausted and worn out by natural decay, rather than by any notable well-characterized disease; though it is not improbable, from such details as have reached us, that it was the climacteric malady which destroyed him.

With some of Mr. Boyle's works we are all acquainted. Boerhave, who ought to be authority with physicians, said, which of Mr. Boyle's writings shall I recommend to you? All of them: to him we owe the secrets of fire, air, water, animals, vegetables, fossils; so that from his works may be deduced the whole system of natural knowledge. He did, indeed,

"Look through nature, up to nature's God."

And to the accomplishments of the scholar and philosopher he added the most exalted piety, and the purest sanctity of manners; and the end and aim of all his inquiries into nature, was to do honour to its great Maker.

Sir Isaac Newton was born so puny and sickly a child, that his mother thought he could not live many days; yet his life was protracted to 84 years.

Does this appear to any of you marvellous? Let him recollect that it is probable extraordinary care was thrown around his diminutive helplessness; that this close attention to all the imperfections of his tender frame would be continued to the period of its complete development; that such habitual watchfulness over all its movements would, at length, render his life more secure than that of a robust habit, which might, by negligence, be surprised into danger and death. The uncertainty of human life of which we all complain, is rendered more uncertain by our own improvidence and inattention, and by a misuse of our strength, which, under certain indispositions, allies itself with disease, and aids it in the destruction of the vital spirit. This is most observable in inflammations, and in apoplexies, and in other ills also where the natural abundance of blood, if circulated quietly, constitutes health; but in the slightest excess and hurry, a dangerous plethora. Sir Isaac died at last of the stone. This evil did not manifest itself until a very short time before his death. He had taken a house at Kensington, in hopes of remedying a slight embarrassment in his breathing; and having occasion to come to town, to attend a council of the Royal Society, he suffered torments the next day, which never ceased till they had destroyed him. Dr. Mead and Mr. Cheselden, who were called to him, were of opinion that the stone had been imbedded in the substance of the bladder, and was moved from its quiet position by the jolting of the carriage. Whatever had occasioned his distress, Sir Isaac never betrayed an impatient feeling, but was entirely resigned to the will of the Almighty, and sought and found comfort, not in his philosophy—not in the fame of his optical experiments, and of the demonstration of the planetary orbits from the principle of gravity—for he knew that

"——— nec quicquam tibi prodest,
Aërias tentasse domos, animoque rotundum
Percurrisse polum, morituro!"—Hor.

no; but in contemplating the benevolence and mercy of God, and in a humble hope of the intercession of His Son.

It is recorded in his epitaph, that he asserted in his philosophy the majesty of God, and exhibited in his conduct the simplicity of the gospel; and a philosopher of high credit of modern day has remarked, that it is one of the proudest triumphs of the Christian faith, that he, who, among all the individuals of his species, possessed the highest intellectual powers, was not only a learned and profound divine, but a firm believer in the great doctrines of religion.

I should be glad to assist in refuting the allegation made originally, I believe, by Huygens, a foreigner, upon the authority of a letter from a young man at Cambridge, and lately repeated by a most respectable periodical publication, of Sir Isaac Newton's having been insane. It was said that he had suffered a severe mental emotion by the

loss of his papers, containing calculations which it had cost him the labour of many years to make. A candle had been left incautiously upon the table on which these papers lay, and a favourite little spaniel having overturned the candle, had set fire to them and burnt them; and this occasioned a temporary loss of his reason.

I confess I am not satisfied that, whatever degree of disappointment and vexation such an accident might occasion, the result amounted to insanity. It is the business of those who make such a charge, to substantiate it by proof. Accordingly, a letter of Sir Isaac's to Mr. Locke has been called up amongst the arguments in proof the derangement of the author's mind. The letter manifests, indeed, a great deal of irritation—such as intense thought upon an abstruse subject, long continued, without the intervention and refreshment of sleep, might occasion; but a subsequent one, written a fortnight afterwards, apologizes for the rudeness and discourtesy of the former, and refers it to his not having slept for an hour together any night, and for five successive nights not a wink. Mr. Locke's reply to this does not convey the slightest suspicion that he entertained such a notion; and it is written with so tender and unaffected a veneration for the good as well as great qualities of the excellent person to whom it is addressed, as demonstrates at once the conscious integrity of the writer, and the superiority of his mind to the irritation of little passions. On Mr. Locke's construction, therefore, of Sir Isaac's letter, and on the view which so good a judge of mind as Mr. Locke took of the state of Sir Isaac's faculties, I rest the decision of this question.

What I have now said of Mr. Locke, may, perhaps, incline you to desire to hear more of this great man. Besides, he was one of you; for he took his degree of M.B at Christ Church, Oxford, when he had been a Westminter student, and owed his first introduction to the world to having administered to the health of Lord Ashley, afterwards Earl of Shaftesbury; who had come to Oxford for the purpose of consulting Dr. Thomas, an eminent physician there. The Doctor being called out of town, requested Mr. Locke to attend his Lordship till his return. This was the foundation of an intimacy between Mr. Locke and his patient ever afterwards.

I may remind you, moreover, that by the kindness of the late Lord King, a paper was read here, in the year 1829, containing the details of a case of tic douloureux, in the person of the Countess of Northumberland, at Paris, treated by Mr. Locke; and we have also the testimony of Sydenham to Mr. Locke's medical knowledge, who says, "Nosti prætereà quam huic meæ methodo suffragantem habeam, qui intimius per omnia perspexerat. utrique nostrum conjunctissimum Dominum Joannem Locke, quo quidem viro, sive ingenio judicioque acri et subacto, sive etiam antiquis, hoc est, optimis moribus, vix superiorem quemquam inter eos qui nunc sunt homines repertum iri confido, paucissimos certè pares."

Locke, then, was a physician; and who amongst you does not feel a pleasure in remembering that the honourable profession to which he has attached himself, was the profession to which Mr. Locke applied the powers of his great mind?—and why should we not all take pride in the observation of that eminent scholar and statesman, the late Lord Grenville, that, "from the very first dawn of reviving letters to the present moment, there never has been a period, in this country, when the masters of medicine amongst us have not made manifest the happy influence of that pursuit on the cultivation of all the other branches of philosophy."

Mr. Locke's health was always delicate, and he was subject to attacks of asthma, which sometimes compelled him to go abroad in search of a less fickle atmosphere than that of his own country. He lived, however, to 73 years of age, and died on the 28th of October, 1704, at the house of Sir Francis Masham, at Oates, in Surrey, where he had been domesticated any time within the last 14 years of his life. He was perfectly aware, it seems, that his days were numbered, and was well prepared for the awful moment of separation from this world. We have, from the authority of Lady Masham herself, the best account of the last hours of his life. Having desired that he might be remembered at evening prayers, she asked if he had any objection to the domestics of the family attending the service in his chamber? To which he replied that he

had none. When prayers were over, he gave some orders with great serenity of mind, and an occasion offering of speaking of the goodness of God, he especially extolled the love which God shewed to man, in justifying him by faith in Jesus Christ. He returned him thanks in particular for having called him to the knowledge of that divine Saviour. He exhorted all about him to read the Holy Scriptures attentively, and to apply themselves sincerely to the practice of all their duties, adding expressly, that by these means they would be more happy in this world, and secure to themselves the possession of eternal felicity hereafter. He passed the whole night without sleep, and desired next day to be carried into his closet; where, after dozing a little, he ceased to breathe about 3 in the afternoon, without any indication of pain or suffering.

Mr. Addison died at the age of 47, of dropsy, brought on probably by a disease of the liver. The habits of life of the higher orders of society in Mr. Addison's time were less cautious, and less compatible with health than they are at present. In proof of this, we may notice the greater comparative longevity at the beginning of this century, than was found at the commencement of the last. The Northampton Tables, which were published in the middle of the 18th century, give only 4 as the average number of those who had arrived at 100 years of age and upwards, out of a million. Whereas the population returns of 1821 and 1832 give 26 as the average number of those who had reached 100 and upwards, out of a million. Habitual suppers, and more wine drank after dinner, and after supper, contributed something to the formation of diseases which shortened life; and where these potations were indulged in by literary men, who took no exercise, it is probable that their effect was still more pernicious. Pope has given us a detail of Addison's familiar day, by which it appears that he studied all morning, then dined at a tavern, and went afterwards to Button's. From the coffee-house he went again to the tavern, where he often sat late, and drank too much wine.

But these nocturnal symposia, however protracted and unwholesome, did not prevent nor retard those effusions of graceful humour which the next morning's study produced; nor was there reason, we hope, for remorse, which is sure to accompany the slightest admixture of depravity with an inveterate habit. Accordingly, when the hour of his dissolution approached, he sent for his son-in-law, the Earl of Warwick, that he might see in what peace a Christian could die!

As a describer of life and manners, Dr. Johnson observes that Addison must be allowed to stand first of the foremost rank; and it is his peculiar merit to have made his wit subservient to virtue. All the enchantment of fancy, and all the cogency of argument are employed to recommend to the reader his real interest—the care of pleasing the Author of his being.

Sir William Jones, after a protracted evening walk in an unwholesome quarter in the neighbourhood of Calcutta, was seized with a shivering fit, which was followed with fever, and by symptoms of an abscess in the liver, a common disease in Bengal, and died on the 9th day of his illness, in the 47th year of his age.

It is difficult to withhold an expression of one's wonder at the extent of knowledge he had acquired in languages, arts, and sciences, in the course of so short a life. His acquaintance with Grecian literature was extensive and profound, and in the modern dialects of Europe, French, Italian, Spanish, Portuguese, and German, he was thoroughly conversant. The language of Constantinople also was familiar to him, and of the Chinese character and tongue he had learned enough to enable him to translate an Ode of Confucius. His skill in the idioms of India, Persia, and Arabia, has perhaps never been surpassed by any European; and his compositions on oriental subjects display a taste which we seldom find in the writings of those who had preceded him in these tracts of literature.

In his eighth anniversary discourse to the Asiatic Society, he remarks, that theological inquiries are no part of the subject he was then discussing; but he could not refrain from adding, that the collection of tracts which, from their excellency, we call "the Scriptures," contain, independently of a divine origin, more true sublimity, more exquisite beauty, purer morality, more important history, and finer strains both of poetry

and eloquence, than could be collected within the same compass from all other books that were ever composed in any age or in any idiom. The two parts of which the Scriptures consist are connected by a chain of compositions which bear no resemblance, in form or style, to any that can be produced from the stores of Grecian, Indian, Persian, or even Arabian learning: the antiquity of these compositions no man doubts, and the unstrained application of them to events long subsequent to their publication, is a solid ground of belief that they were genuine productions, and consequently inspired.

Of Dr. Johnson it will be much more difficult to say too little than too much. The very interesting book of his life is to be found upon every gentleman's table, and with his works many of you are better acquainted, perhaps, than I am. He died of dropsy, brought on by repeated asthmatic attacks, which had annoyed him many years, and had often driven him from the pure air of Streatham, where he spent a good deal of time, by the friendship of Mr. Thrale, into the solitude and closeness of Bolt-court, Fleet-street, in which he found his respiration more easy than any where else. So much for the caprice of asthma, of which my experience has furnished me with many instances.

I remember a gentleman, subject to fits of asthma, who built himself a house in an elevated beautiful situation in Surrey, and whilst it was building, lived in a cottage in a valley beneath it. The first night he attempted to sleep in his new residence, he suffered so much from distress in his breathing, that he returned to the cottage, intending to make a second experiment, under better auspices he hoped, when he should have recovered from his late suffering and alarm. The same experiment was made again and again, with the same unhappy consequences, until at length he was obliged to abandon his new abode entirely, and to dispose of it.

Another example occurs in my recollection, in the person of a patient who consulted Sir George Baker, as well as myself, upon an asthma, which had distressed him grievously. We advised him to travel, as it was in his power to do so, in search of an air that would suit him, and wherever he should find it, there to fix his residence, for some time at least. In the course of his travels, he arrived at Lyme, in Dorsetshire, where he breathed with unusual comfort. After a sojournment of three weeks at Lyme, he was able to walk up a considerable hill out of town, at a quick pace.

Dr. Johnson was born of a melancholic temperament, and of a scrofulous habit. Such a constitution of mind and body would render a man prone to act upon impulses, and to disclose one of the characteristic symptoms of insanity; particularly if he did not entertain a strong religious principle, which might be ready to interpose between the purpose and the deed, and to arrest violence, until reason, in abeyance for a while, should recover its proper authority and sway. Dr. Johnson had this religious principle in its most lively vigour, and a power of reasoning also beyond that of most men of his time. From dejection of spirit, he found relief in society; and it was as happy for his associates and for the world at large, as for himself, that he sought it there, for his powers of conversation were extraordinary, and furnished inexhaustible instruction to those who listened to him. And there is scarcely a writer, whose profession was not divinity, that has so frequently testified his belief of the sacred writings, has appealed to them with such unbounded submission, or mentioned them with such unvaried reverence.

Thus have I laid before you an account of the deaths of some of the most eminent philosophers of the two last centuries in this country; and it cannot have escaped your observation, that in giving also their religious sentiments, I had it in view to bring to your recollection such their invaluable testimony to the truth of the Gospel. I know that in matters of eternal concern, the authority of the highest human opinions has no claim to be admitted as a *sufficient* ground of belief. It is every man's duty to weigh well, and to consider for himself, the reasons of his faith. But it cannot fail to encourage and to confirm his own conclusions, to know that these, the best, the wisest, the most learned of mankind, who devoted much of their time to the study of the Holy Scriptures, arrived at the same results. Bishop Horsley has observed, that the man of science and speculation, the

more his knowledge enlarges, loses his attachment to a principle to which the barbarian adheres—that of measuring the probability of strange facts by his own experience.

And shall physicians want these subjects of speculation, to encourage their hopes, and to enlarge their faith in the promises of the Gospel? Might not Mr. Locke have been led to his lofty contemplations, which ended in so solemn a conviction of divine truth, by those early studies of the nature of "man's small universe," which were to prepare him for our profession? And did not their early converse with the awful circumstances attending the last scene of human life, suggest to Sydenham, to Boerhave, to Heberden, and to Baillie (what, blessed be God! it has suggested to myself), not the hope only, but the confident expectation, of another and a better world, of which they have testified to us and to posterity.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

A Key to Structural, Physiological, and Systematic Botany: for the use of Classes. By JOHN LINDLEY, Ph. D., F.R.S., &c. 1835.

Remarks on the Geographical Distribution of British Plants: chiefly in connexion with latitude, elevation, and climate. By HEWETT C. WATSON. 1835.

The New Botanist's Guide to the Localities of the Rarer Plants of Great Britain. By HEWETT C. WATSON. 1835.

WE are induced to group these works together, not so much for their referring to the same science, but because they stand towards each other in the relation of the starting-point and the goal. The views unfolded, and the language of signs employed in the works of Mr. Watson, can neither be understood nor appreciated, except by the student who has had the benefit of being educated according to the principles explained in the elementary work of Dr. Lindley. Of this, therefore, we shall first speak. It consists of new editions of two productions of the same zealous and accomplished botanist, by which he has already greatly contributed to elevate the attainments of the rising generation of botanists—viz. "The First Principles of Botany," and the "Nixus Plantarium," now presented in an English dress. As two editions of the former have received the seal of approbation from the most enlightened teachers and diligent pupils, it is not necessary to say more of it than that the alterations in it tend to bring it up to the level of the science of the day, as understood by the most distinguished botanists; and that with such aphorisms or texts to discourse from, it must evince great inability on the part of the teacher, or carelessness and incapacity on the part of the student, if the number of scientific and philosophical botanists be not greatly augmented by its farther use. Of the Nixus more might be said, if it were requisite here, or our limits permitted us to discuss the principles on which it is constructed. But we cannot do more than remark that, however great the agreement of most botanists may be with respect to the principles or rules which determine the boundaries of the different natural groups, very great diversity of opinion exists among the most distinguished masters of the science, with regard to the co-ordination of these groups, as must be clear to any one who will compare the Nixus with Professor von Martin's "Conspectus Regni Vegetabilis," published about the same time, having appeared at Nürnburg in 1835. We are far from objecting, however, to such a volume of arrangement being submitted to the student, if it be understood as provisional, and not definitive. It will then constitute a very admirable subject for the exercise of their powers of observation and reasoning. We must introduce another cautionary remark, and that is, to warn the student against committing to heart the succinct and very excellent characters of the different tribes, and supposing that when asked the diagnostic marks of any tribe, if he can repeat these short sentences trippingly on the tongue, that is all that is necessary. If ever he lose sight of the great principle, which is one of the

leading characteristics of the natural method, that the presence of these peculiarities of structure stated in the definition, are indications of the co-existence of certain other peculiarities, he will scarcely be entitled to rank higher than those self-styled botanists, who are perfectly satisfied with themselves when they can state respecting a plant, that it belongs to the pentandria, monogynia, or triandria, trigynia, &c.

The errors we have perceived, or supposed we have perceived, are so trifling, that if the book were not likely to pass into the hands of thousands of beginners, we should not mention them. First, in § 5 we do not exactly understand what is meant. "Plants consist of a membranous transparent tissue, chemically composed of a *hygrometrical* (?) combination of oxygen, hydrogen, and carbon, to which nitrogen is occasionally superadded." 2nd. The reference (101) in § 89 must be incorrect: we presume it is intended to be (218). Lastly, in the Nixus, p. 46, as an example of the Anonaceæ, the *piper æthiopicum* is given: now either some other plant of the tribe should have been chosen, or its real botanical name, *uvara æthiopica*, been used, lest the tyro should be led to suppose that the genus Piper belonged to the Anonaceæ.

The higher the general character of any work for excellence, the more need of accuracy in every part of it.

Mr. Watson, by the publication of the second work on the list, may be said to have taken possession of a field of wide extent and great interest, scarcely any portion of which has been cultivated by preceding botanists. Indeed, the subject of botanical geography, as relates to the world at large, has received very little attention from British botanists, if we except Brown and Hooker; nor was the subject ever alluded to in any of our elementary works, till the publication of Dr. Lindley's Introduction to Botany, in 1832; though a small treatise, or rather sketch, on the subject, had been published by Mr. Barton, in 1827, with maps. No remarks upon the distribution of plants in Britain existed till Mr. Watson printed, for private circulation, in 1832, "Outlines of the Geographical Distribution of British Plants." Some notices on the subject, from the pen of Mr. Arnott, were incorporated with the description of Britain in the Encyclopædia of Geography; and some calculations of the relative numbers of species found in certain districts, occur in Dr. Greville's "Flora Edinensis," and Winch's "Flora of Northumberland and Durham," as well as Johnston's "Flora of Berwick-upon-Tweed." Professor Henslow has made some calculations on the subject, and one or two other observers, such as Dr. Boice (in his inaugural dissertation), and Mr. Macgillivray, have contributed to our knowledge upon these points. But after assigning every fair amount of merit to these different writers, still to Mr. Watson is due the praise of taking a comprehensive view of the distribution of plants in Britain, and investigating the causes which influence their distribution. Much of what he has embodied in his work has been obtained by his own observation and inspection of different parts of England and Scotland, by great personal exertion. But difficult as the first step is in such undertakings, Mr. Watson has taken so vast a stride as to render all the subsequent steps comparatively easy; yet he does not intend to remain content with what he has accomplished, but regards it only as the ground-work of a more extensive treatise; and he requests, in his preface, assistance from all who are capable of affording it. To contribute towards procuring information, we here repeat the titles of the subjects he deems desiderata for the prosecution of his object:—

"1. Altitudes of hills, lakes, and fixed objects.

2. Information on the climate of places, particularly with reference to the temperature and humidity.

3. Dates of the first flowering of any of the following *wild* plants, if carefully noted:—

Corylus Avellana	Ranunculus Ficaria
Prunus spinosa	Viola canina
Cratægus Oxyacantha	Oxalis Acetosella
Rosa canina	Veronica Chamædrys
Lonicera Periclymenum	Hyacinthus non-scriptus
Ulex nanus	Arum maculatum
Hedera Helix	Cardamine pratensis
Erica Tetralix	Lotus corniculatus
—— cinerea	Vicia Cracca
Calluna vulgaris	Digitalis purpurea
Cytisus scoparius	Linaria vulgaris
Ilex Aquifolium	Senecio Jacobæa.

4. The highest or lowest places at which any species has been observed,

whether in absolute height, in comparison with the appearance or cessation of other species, or in relation to the parts of particular mountains, as at the base, middle, or summit; provided such heights are not considerably within the limits assigned to the particular species in the present work.

5. Unpublished, or *recently confirmed* localities for the less common species; as also, localities near the boundary-lines of such as are not spread over the whole island.

6. Actual specimens in confirmation of the localities, heights, &c. will be most welcome, and be preserved in the view of making them public evidence hereafter. The name of the *donor*, and that of the *county*, should INVARIABLY be written on the ticket accompanying each specimen; also the name of the person supposed to have gathered the specimen, if not the donor himself. Neglect of this renders the specimens of little value.

7. Notices of changes in the habits or characters of plants, in connexion with differences of situation and season.

8. Information as to the success attending attempts to cultivate plants of milder or warmer climates, without the aid of artificial heat. Also, notices of the influence of elevation on the produce of fields and gardens.

9. Any corrections or amendments relating to the contents of this volume, as well as criticisms and suggestions for improvement, will be received with pleasure by the author, if allowed to make them public in case it should appear desirable to do so."

The first object may be accomplished more accurately, as well as more easily, than hitherto, by a new species of barometer, invented by John T. Cooper, Esq., which he proposes to call the "*Hydropneumatic*," which is more portable than those heretofore used.

As the subject of medical topography is now more likely to receive a greater share of professional attention than has previously been the case in Britain, we have entered into a very attentive examination of Mr. Watson's work, in order to ascertain how far it will be serviceable in making observations on vegetation and climate, as connected with health and disease. Though some popular ideas on the subject of this connexion exists, accurate data are very deficient in the different counties of England and Scotland; but we trust that our stock of these will annually be increased; and have very little fear upon this point with regard to England, since the attention of the profession has been so ably directed to it in the proposal of Dr. Conolly, submitted to the Provincial Association of Physicians and Surgeons. That is already beginning to produce good fruit, and to augment the amount of this, the great requisite is to interest many observers by convincing them of its importance. In an able paper in the Edin. Med. and Surgical Journal, for April 1821, entitled, "Sketch of a Plan for Memoirs on Medical Topography," occurs the following passage:—"The early appearance of many plants, and the slowness or rapidity of their vegetation, the torpidity, arrival and departure, of many quadrupeds, birds, and insects, will often mark more strongly than the indications of the glass the nature of a climate; and the judicious naturalist will avail himself of the circumstances in his topographical description. Strong indications of the healthfulness of a country may be drawn from its plants and animals; and the approach of unhealthy seasons has often been marked by the changes produced on them. In America, the common house-fly has disappeared, while musquitoes have been multiplied, and several new insects have been observed previous to some of their malignant epidemics; and at similar periods certain trees have emitted unusual smells, and the leaves of others have fallen prematurely, and the fruits have been of inferior size and quality; while, in some places, an unusual growth of vegetable productions (fungi) has preceded the most destructive scourges of mankind."—P. 167.

The truth of these remarks is best exemplified in tropical climates, or the warmer countries of Europe, as may be seen by reference to the various valuable papers on Medical Topography, in the Transactions of the Medical and Physical Society of Calcutta, and "Koreff, de regionibus Italiæ aere pernicioso contaminatis observationes," Berlin, 1817. But in every country, plants (even more than animals) are the most delicate and correct of all barometers and thermometers; the difference of date of flowering of the same species of plant, in different situations, affords

indications of the existence of causes of difference of climate, which cannot be ascertained by any instrument that man has hitherto contrived. Sir Edward Parry, in his Second Voyage, in 1822, p. 240, deemed it important to mention, and mark in Italics, that "the first flower of the *saxifraga oppositifolia* was brought on board as a matter of curiosity, by the botanists, on the 9th of June, *or one day later* than it made its appearance at Melville Island, in 1820." And why this importance attached to what many may think a very trifling difference? Because, in their situation, every criterion of the approach of warmer weather was interesting, to say nothing of the difference of the date of flowering of this plant being accompanied by other differences which materially affected their comforts and prospects of release from their icy captivity. At p. 241 he states—

"June 16th.—Having thus reported our own progress for the last week, I cannot omit saying something of that which nature had been making in the same interval. A few more flowers of the saxifraga had here and there been procured, but they were still curiosities; the more so as being almost the only ones that had yet made their appearance. Some water had now been obtained from the shore, by baling a gallon or two from each little pool, and carrying a cask about on a sledge, to be thus filled. At Melville Island, at the same period, the ravines were beginning to be dangerous to pass, and were actually impassable during the third week in June."

Mr. Watson, at page 37, gives a view of the date of flowering of different plants at different places in Britain, from which it appears that the same species flowers at Barnstaple thirty days earlier than at Strathpeffer, in Rosslin. If we take a more extended range than the length of Britain presents, we shall find a still greater difference: the almond tree (*Amygdalus communis*) flowers at Smyrna in the earliest half of February; in Germany, the latter half of April; and at Christiana, about the beginning of June. It is greatly to be desired that records were kept of the dates at which plants ripen their fruits and seeds, as well as of their dates of flowering. Indeed, it is worthy of remark, that the causes which determine the flowering of a plant are different in degree, if not in kind, from those which determine the ripening of its seeds. And we are the more desirous of directing attention to this point, as the only omission of importance which we have perceived in that part of Mr. Watson's book where he treats of the meteorological peculiarities of Britain, is in some degree connected with this subject. He has taken no notice of the difference of the intensity of solar light on the western and eastern sides of this island, though it affords the only plausible explanation of some very remarkable as well as important facts connected with vegetation. Mr. Barton, in the work before alluded to, states (p. 22), "*Wheat* demands a warmer climate than barley or oats. This grain is not found to succeed in the west of Scotland, the summer's sun being insufficient to ripen it." Even in England, the western side of the island appears better adapted to the growth of grass than of corn; and, accordingly, it may be observed, in every part of the kingdom, that corn is carried from east to west, while cattle are driven from west to east. All our principal corn counties are situated on the eastern side of the island, from the Lothians, in Scotland, to Kent, the south-eastern county of England." And again (p. 29), "At the further extremity of that long promontory, which, projecting into the Atlantic, forms at once the most southern and the most western point of England, neither the *apricot*, the *vine*, nor the *greengage plum*, produce ripe fruit, for want, as it should appear, of sufficiently powerful sun-beams."

Mr. Watson, p. 63, also states, "Wheat is cultivated only in the lower part of the region, (which Mr. Watson terms the *upland*) and in the highlands, chiefly along the eastern coast." P. 64. "On the east coast of Sutherland, the peach will ripen against walls with the aid of a glass sash, perhaps even without." Thus we see, that while the apricot does not ripen in Cornwall, the most south-western country of England, in lat. 50°, the peach ripens in Sutherlandshire, nearly the most north-eastern county of Scotland, in lat. 58°. This remarkable difference is ascribed to the greater number of clouds prevailing on the west coast, on which are placed the highest mountains, taking the whole length of the country, (Watson, p. 3—

17) and which attract the vapours from the Atlantic. The clouds intercept the direct rays of the sun, and only allow diffused light to fall on the plants and fruits. This difference is the more important to be noticed, since the observations of Dr. Daubeny, which establish the law, that the influence of lights on plants depends less on the heating than on the *illuminating* power of the rays.

There are various other important points touched upon in Mr. W.'s book which we had marked for comment, but the length to which this notice has already been extended compels us to confine ourselves to one, viz. the 5th section—"Remarks on the distribution of British plants over other countries." This section we deem of great interest and importance, but we can only direct our attention to some farther illustrative data, furnished by Professor Schouw, on the geographical distribution of trees on the Scandinavian Peninsula, which are printed in London's Magazine of Natural History, for February, 1836.

We feel assured we have said enough, though much less than the interesting nature of the book inclines us to do, to induce every one who attends either to botany as a pure science, or to the important applications of which it is capable for elucidating climate, and other important matters connected with the health of the community, to procure it for themselves, and study it with the attention it merits.

Mr. Watson has promised two additional volumes, in farther illustration of the subject; one of which is to contain plans, maps, and more extended tables. Till these appear, we beg to recommend Mr. Barton's Lecture on the "Geography of Plants," the maps of which are extremely useful. A map, which is also very useful, is to be found in Dr. Prout's Bridgewater Treatise; and one, but on too small a scale, in the article "Meteorology," in the Encyclopædia Metropolitana; but the article itself will be found worthy of perusal.

The third work on our list is part and parcel of that which we have above spoken of. In this view Mr. Watson regards it, and it is undoubtedly the true one, but many will use it as an independent work, being in reality a new botanist's guide to those who search for plants as isolated productions, and without reference to the locality in which they grow. Even for this last purpose, it is much more complete than the Botanist's Guide of Turner and Dillwyn, and is more commodious, being in one volume. In one respect only do we consider it inferior, and that is, in the omission of stations of the cryptogamic plants. Humboldt has remarked, that there is less diversity in the cryptogamic vegetation of different countries, which differ considerably in latitude and other circumstances, than the flowering plants. We conceive, therefore, that as bearing upon the subject of medical topography, the cryptogamic plants of a district are worthy of enumeration, as any considerable difference found among them would seem to point out the existence of some more than usually powerful cause, modifying the climate of the locality. Mr. Watson merits our best thanks, however, for what he has done; and we sincerely wish him every success in the farther prosecution of his labours, as well as solicit for him the assistance which he desires, and which we are sure he will receive from the liberal-minded botanists of Great Britain.

MEDICAL GAZETTE.

Saturday, February 27, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

THE *HYGEIAN* QUACKERY.

THE utter rooting out of all quackery from the world, must, we suppose, by this time, be given up as a hopeless enterprise. In spite of the boasted lights of science, and the diffusion of knowledge, which are said to be daily dispelling what remains of the darkness and ignorance bequeathed to us by our ancestors, matters (so far as we can see) look pretty much as they did in the times of old. When Pliny, some 1800 years ago, could write of his contemporaries, in respect to their predilection for mysteries in medicine,—*minus credunt, quæ ad salutem suam pertinent, si intelligunt*—and add, concerning the parties who were in the habit of taking

advantage of this wilful blindness, *itaque hercule in hac artium sola evenit, ut cuicunque medicum se professo statim credatur, cum sit periculum in nullo mendacio majus*,—the illustrious natural historian may be considered as not only stating what was the case in his own days, but for ages before him, and, with a sort of second sight, what is likely to remain a truth to the end of time.

Our belief is, that quackery has been permitted, in the great scale of natural and moral dispensation, to run its career with medicine, in order to serve as a spur, or a scourge, to quicken the activity of those who profess the legitimate healing art—to put their zeal and their faith to the test; much in the same manner as heresy and infidelity are allowed to figure in the same course with true religion.

But such a persuasion by no means leads to the principle that quackery should for a moment be tolerated, or that we should relax in our efforts to spurn and put beneath our feet the impudent impostors who infest society. And of all impostors, who can be looked upon as more thoroughly offensive or detestable, than those who, like the *Rev.* Robert Taylor, in the garb and disguise of a respected calling, abandon themselves to vile purposes, and for a little paltry notoriety, or lucre, prostitute the profession to which they belong? Such persons, however, are luckily rare, and the odour of their presence, when they do make their appearance, is generally too rank for ordinary nostrils long to endure.

The quackery that prevails at different times is of various and diversified character. Not long since we had it in a sort of *parvenu* shape; from the humblest origin it reared its head among the high places, and obtained a short-lived footing within the aristocratic circle. The late St. John Long, compared with the sort of people who now solicit public attention, and practise on public gullibility, was a respectable personage: he had some notion of the decencies to be observed in ministering to the cure of disease; and though he committed certain fatal blunders, he had not, we believe, a tithe of the mischief to atone for that has been perpetrated by his successors. The fellows who at present prey on the community, and who profess the *Morisonian* humbug, calculate so far on the credulity and love of mysticism prevalent among the middle and lower classes, as to serve up daily in the public prints manifestoes, addresses, and other puff documents of the coarsest texture. They must find it adapted to their purpose, or they would not persevere. They have even the presumption to affect to *theorize*—to *reason*—to support with *argument* the principles which they announce. Any thing more grossly clumsy, we believe was never before attempted to be thrust down the public throat—capacious as it is for swallowing the boluses of quacks. Down, however, the lumps of stupidity go, along with the lumps of pills—both alike suited to strong stomachs. It would be, indeed, only a ludicrous exhibition were it confined to such maws: but the weak in mind and the weak in body form a large proportion of the community, and to such this sort of "bolting" is but too often fatal.

That "*blood makes blood*" is one of the precious dicta of the "Hygeists:" we begin to believe the maxim ourselves, when we see that one homicide by the *hygeian* pills leads to another in quick succession: the blood already stamped on *the* pills—*the blood of repeated manslaughters*—is not enough to deter the unhappy dupes who hunger for them; and many of whom must pay the price of their depraved appetite with their lives. It is a curious instance of the infatuation which becomes occasion-

ally epidemic in large and *soi-disant* enlightened states: and to the philosopher who would estimate the amount of common sense prevailing in this country, and more particularly in this great metropolis at present, it must afford a valuable subject for meditation. We know not that any of our statisticians, by the way, have ever attempted calculations of this sort—the estimating the amount of rational principles prevailing in communities at different periods—but we suggest that the history of the rise and progress of quackery in the world, if honestly recorded, would afford a large portion of the required data. But to come to the point which induced these observations.

Our readers have, doubtless, read in the public prints of last week, (we merely had room to mention the result ourselves), some account of the inquest held at Ratcliff workhouse, on a new victim of the Morison quackery. The verdict pronounced by the jury in that case was one arrived at not hastily, but after a patient hearing of much evidence for several days; and nothing could be clearer, from the circumstances deposed by most of the witnesses, than that the verdict was a just one—that manslaughter of an aggravated nature had been committed by the administration of the Morison quack pills. But the most remarkable feature in the inquest—that sort of judicial investigation being in itself now by no means novel in reference to the Morison quackery,—the most striking circumstance, we say, attending this inquest, was the presence of certain individuals, calling themselves regularly educated medical men, who came forward as the humble disciples of the *Hygeist*, to defend the propriety of administering certain medicines, of the composition of which they professed to know nothing. There was a Dr. Lynch, an Edinburgh graduate, who took the lead on this occasion, in advocating what he calls Hygeiaism, and who was very chary in announcing himself as the paid lecturer of Morison: he was, indeed, touchy in the extreme when interrogated on this point. He has, however, since that, we perceive, advertised himself in the newspapers in connexion with his patron, appending his signature, along with that of Morison, to a tissue of the most stupid and beastly trash. He has also given notice of the continuation of his course of lectures at Exeter Hall, to which, like the preceding ones, the public are invited *gratis;* the subject of the lectures being "Hygeian Medicine," alias, Morison's pills. Now here is the *professional* gentleman whom Morison has retained as his great apostle and advocate, and of whose conjunction the *Hygeist* is abundantly proud; referring all parties who yearn for the vegetable pills to the Doctor, and showing his gratitude, no doubt, in a hundred ways that the public are not aware of. We have no wish to stamp the professional character of any medical man with ignominy; but if, as we have said, quackery be to medicine what avowed infidelity is to religion, we leave Dr. Lynch to guess to whom, in modern times, we must compare *him;* for he has, in the theological profession, a pretty exact and faithful counterpart*.

Of the other medical man, who figured in Morison's defence, (a Mr. Tothill or Tuthill of Exeter), the sort of evidence he gave will serve as a specimen. He knew nothing, and cared nothing, about the ingredients of Morison's pills; but he was full of gratitude for the benefit they had done himself, when he laboured under (we believe)

* *Dr.* Lynch, at the inquest, informed the public that he had formerly lectured at Mr. Grainger's school, in the Borough; but Mr. Grainger has since explained, that the *Dr.* never gave more than three or four lectures there. The subject was morbid anatomy—not Hygeian quackery; nor did Mr. G. at that time suspect the *Dr.* to be in any respect a "Hygeist."

rheumatism. He had since then thrown ordinary physic to the dogs, and taken to the Hygeian: he had become the great Hygeian agent in South Devon, and was deemed of so much importance by his principal as to be brought up to London to give his testimony at the inquest. The opinion elicited from him, on cross-examination, with reference to the efficacy of *the* pills, was peculiar; at least we never heard the like expressed of any medicinal substance equally *harmless*. An old distich repeated, not always very trippingly on the tongue, especially when repeated rapidly, concerning tobacco,

> "—— If you be well, it will make you sick—
> —— 'twill make you well, if you be sick,"—

comes pretty near Mr. Tuthill's affirmation, or oath rather, about Morison's pills:—" 'Pon my soul," says the respectable witness, " if you were to take a dozen boxes of them, they would only make you sick; and if you are sick, you have only to take more of them and get well again!"

Such are the samples of *medical* men who have taken up " hygeiaism," and who no doubt expect to make it a profitable thing: we would beg leave to offer them a little advice, however — and that is, to take care lest they find it ere long a dangerous speculation. The coroner begins to come very often into somewhat awkward contact with the " agents," and verdicts of " manslaughter," followed by fine and imprisonment, are not so very unfrequent. It may not be pleasant, neither, to exchange Exeter, or Exeter Hall, for one of his Majesty's gaols. These hints we throw out to the new hygeists, as proper for them to chew the cud upon. To *them* we say nothing of the position in which they place themselves in the eyes of that profession to which they claim to belong; they have taken their measures deliberately, and, of course, are determined to abide by them. But to the profession itself we have a word or two to offer.

Quackery stalks abroad in more gross and disgusting form than it has ever before assumed; it bids defiance to the regular practitioner; it denounces him as the slave of ignorance and prejudice; and while it associates with it a few unworthy individuals, who boast to belong to the medical corporations, it flies in the teeth of those very bodies corporate, from which all well-educated medical men derive their privileges to practise.

Are professional men to look on with apathy under this provocation? Are those lawless vagabonds to be suffered to cajole the public—to tamper with, and often to destroy, the lives of his Majesty's subjects—and to insult the regularly-educated practitioner at the same time? Forbid it, prudence! forbid it, common sense! The proper course, then, is manifest: let every man in the profession exert himself within his sphere to expose the folly—the wickedness, of quackery: let him put away his contempt for charlatanism, for it has reared itself, through his sufferance, to a height not to be despised: let him attack it in its strong holds, so that if it be not extinguished in the contest, it may at least receive a check salutary to itself, and conducive to the public good.

CONVERSAZIONI AT THE COLLEGE OF PHYSICIANS.

THE meetings at the College of Physicians commenced for the season on Monday evening, on which occasion the room was, as usual, crowded to overflowing. The learned President occupied the chair, and was supported by the two Archbishops, the First Lord of the Treasury, and several other of his Majesty's Ministers,—by many dignitaries of the Church and of the Law, as well as by an immense assemblage of distinguished persons.

Sir Henry Halford read a paper on the Deaths of some Eminent Philosophers of Modern Times, which was received with much approbation: it formed a continuation of the series of essays on analogous subjects which the learned author has each succeeding year so skilfully adapted to the audience assembled on these occasions. (See a full report of the paper at p. 859, *ante*).

We cannot, however, allow the present opportunity to pass without remarking, that the members of the College ought either to support these meetings in a more efficient manner, or to discontinue them. That the assembling within its walls, at stated periods, of so large a number of the most eminent men in the kingdom, both as to rank and reputation, has a tendency to raise the College itself in public estimation, no one can reasonably doubt; — their presence is a tribute to the profession of physic, the influence of which becomes extended to its members. We should have expected to learn that all the Fellows gave to these meetings their most cordial support, and that the difficulty was not in procuring papers, but in selecting from the abundance of them. Such, however, was not the case last season; and it is on this account that we venture to express our astonishment that an opportunity so favourable of supporting the general interests of their body, should be so utterly disregarded; and that those who invite the scientific and literary public to become their guests should take so little trouble about the intellectual part of their entertaintment. At present the very existence of the meetings depends wholly and exclusively on the exertions of Sir Henry Halford, whose success in diversifying the subjects of his papers, and giving *eclât* to these conversazioni, has been very remarkable; but with his Presidency, unless there be some great change, the meetings must at once cease, and probably for ever.

REMUNERATION OF MEDICAL WITNESSES.

The principle of remunerating medical witnesses was acknowledged last session both by Lords and Commons; and the clause of the County Coroners' Bill for fixing the amount to be paid at from 1*l.* to 2*l.* was carried, and would have become the law of the land, but for the unexpected impediment of some circumstance connected with the forms of parliament. It was understood at the time that the bill was to be reintroduced, and there is, we believe, no doubt of it passing during the present season. Meantime, however, the *honourable* member for Finsbury, anxious, if possible, to gain some credit, has taken this part of the matter out of the hands of Mr. Cripps, the first mover, and is about to bring in, as a measure of his own, and as if it had been his own original design, that provision of the Coroners' Bill which secures a due remuneration to the medical witness, and which parliament last session declared its intention to afford. This is a shabby trick towards those to whom the medical profession is really indebted for first bringing the matter forward; but as it is of little consequence through whose medium the boon is conferred, we most earnestly recommend our brethren to petition in favour of the proposed measure. Such interference on their part is now rendered absolutely necessary, because the circumstance of this fragment of the bill having been taken up by Mr. Wakley, brings its passing into a degree of jeopardy which no one could have anticipated, and which it will require all the influence of medical men with their parliamentary friends to counteract.

THE LATE DR. JOHN CHEYNE.

We regret to announce the death of Dr. Cheyne, formerly of Dublin, and Physician-General to the Forces in Ireland. He was well known to the profession by his various practical dissertations, particularly those on Hydrocephalus, Croup, and other Diseases of Children; by his works on the Pathology of the Pharynx and Bronchia, and on Apoplexy and Lethargy. He also published, conjointly with Dr. Barker, an account of the Epidemical Fever in Ireland; and contributed various papers to the Dublin Hospital Reports, and to the Cyclopædia of Practical Medicine.

Dr. J. Cheyne was born on the 3d February, 1777. He was originally of Leith. After having been some years Surgeon in the Artillery Corps, he returned to Leith, where he obtained considerable practice. In the year 1795 he took the degree of M.D. at Edin-

burgh. Having married an Irish lady, he was induced about the year 1809, to settle in Dublin, where he obtained the appointment of Professor of Medicine, and became Physician to the Meath Hospital. The confidence of the profession in his experience and excellent judgment, with his delicate and honourable conduct, drew him into the highest and extensive practice, and obliged him to resign his public duties, except those belonging to the important post of Physician-General, to which he was appointed in the year 1820. For many years his professional receipts were very large: but his health broke under the fatigue. When in a state of great debility, a domestic calamity occurred, which seemed quite to overwhelm him: one of his sons was accidentally shot while on an excursion in the country; and unfortunately, as Dr. Cheyne hurried from town to his assistance, the postillion rode over and killed a child. These distressing circumstances, we have reason to believe, hastened his retirement from Dublin; his departure from which metropolis drew forth public expressions of regret from all the medical bodies. He brought his family with him to England, and bought a property in Buckinghamshire, where he lived in retirement during the last few years. He died, after an illness of some months, on the 31st January, 1836.

Dr. Cheyne was of the most amiable disposition, joined to a pleasant humour. He felt himself sinking, without losing his natural cheerfulness, and died in the confident hope that he was entering on the better part of his existence.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY,

Tuesday, Feb. 23, 1836.

HENRY EARLE, ESQ. F.R.S. IN THE CHAIR.

THE first paper read this evening was from the pen of Mr. Buller, detailing the particulars of a case of *Dislocation and Fracture of the Lumbar Vertebræ*. A preparation of the bones was exhibited.

At the request of the President, a paper on nearly the same subject, by Mr. R. A. Stafford, was read: it gave an account of a case of *Dislocation and Fracture (?) of the eleventh and twelfth Dorsal Vertebræ*.

It appears that, in August last, the patient, a man 31 years of age, was occupied in cleaning the windows of a first-floor; when, feeling himself become giddy and about to fall, he made a spring backwards, to clear the iron railings of the area beneath: he fell upon his buttocks, and was for a short period senseless. A crowd collected, and Mr. Stafford happening to be in an opposite house, he immediately ran across to the man's assistance. By this time those about him had raised him from the ground, supporting him on his feet. He was extremely pallid, and complained of severe pain in his back, but he had walked one or two steps. He was immediately carried into the house and laid upon a bed. Mr. Stafford examined him. His body was bent forward, and slightly twisted towards the right side. At the eleventh dorsal vertebra the spine projected, and between the spinous process of that bone and the spinous process of the twelfth dorsal vertebra there was a chasm, into which the three first fingers could be placed with ease, being in measurement full two inches in length. The superior parts of the vertebral column projected over the inferior; so that the lower part of the body was carried a little forwards, and the spine was not in the same line as it is in its normal form. There was no paralysis or numbness in the lower extremities, and no loss of motion, excepting the weakness which would naturally ensue from such an accident. The bladder and rectum, as will presently be seen, possessed their full powers, and no other symptom existed to denote so severe an injury to the spine, excepting the pain in the back.

As the slightest movement of the body might have displaced the vertebral column still more (for it was already torn), and thus wounded the medulla, the man was carefully laid upon a litter and carried to the St. Marylebone Infirmary. He then was cautiously placed upon his back on a double-inclined plane bed, at its lowest angle. He could not, however, at first bear this position long, from the extreme severity of the pain of the injured part. He therefore was occasionally moved on his right side, which was done with the greatest care. He was cupped on the injured part as often as the symptoms required the loss of blood, purged, and kept strictly on the antiphlogistic regimen; taking diaphoretics during the febrile action. When the violence of the pain had subsided, which was in about four or five days, he was placed entirely on his back and kept perfectly quiet. The chasm between the eleventh and twelfth dorsal vertebræ gradually lessened, the pain subsided, and the patient in three months left the Infirmary quite well, except the deformity, and being weak in the back.

During the whole treatment, no unto-

ward symptom happened: the bladder and rectum performed their functions naturally, and no paralysis whatever occurred.

It would (as Mr. Stafford observed) be extremely difficult, without a dissection of the spine, to account for the displacement of the vertebræ in this case. The author endeavoured to explain the occurrence in this way:—That in consequence of the sudden jerk given to the back, in endeavouring to clear the palisades (for the man acknowledges that he made an effort, even during his descent, to do so), that the action of the muscles tore asunder the intervertebral substance between the eleventh and twelfth dorsal vertebræ, fracturing or dislocating, at the same time, the articular joints; and hence the gaping or chasm between the two spinous processes. Fracture of the body of the vertebra, with dislocation or fracture of the articular joints, might also have produced the same phenomenon.

The most remarkable feature, perhaps, in the case, is, that the medulla received no injury, and that there were no symptoms at any time to show that there was either pressure upon or any lesion of the cord, or its membranes.

Mr. Earle exhibited the fractured vertebræ to which he had called attention at the last meeting. They had since been sawn longitudinally, and now left no room to doubt that their conformation was owing to a complicated fracture, and not disease of the bones. The spinal cord, at one place, must have been compressed into the calibre of a goose-quill.

A desultory conversation now arose on the subject of injuries of the spine; towards the conclusion of which, the President suggested that it would be desirable to have a paper drawn up containing the joint experience of several of the members; and he thought that this might be best effected in the manner of the old French Academy—by a commission selected from among the Fellows of the Society.

The reading of a paper *On an anormal Structure of the Valves of the Heart*, by Dr. Kingston, was commenced; but, in consequence of the lateness of the hour, it was discontinued—to be renewed at the next evening meeting.

CLINICAL LECTURE

ON

TIC DOULOUREUX;

Delivered at the Middlesex Hospital School,

By Sir Charles Bell.

Before leaving this hospital, I mean to give you some clinical remarks; a practice which I have pursued for one-and-twenty years: it was my earliest duty, and it shall be my last, to the pupils of this hospital.

There is an indescribable pleasure in reflecting on the successful treatment of diseases attended with pain amounting to agony. On Thursday last re appeared a patient (Charles Delafield) in whom some of you were much interested during the early part of last summer. He presented himself a miserable object; his head surrounded with a night-cap and rolls of flannel, which almost hid a face pale and wasted with incessant pain. Seeing him so proper an object of the charity, I gave him a letter, and wished him to come into the house. He expressed himself grateful, but he dared not; for he could not bear the restraint even of lying in bed, and had no relief from pain but in continual work in his business, which was that of a carpenter. His complaint was *tic douloureux*, and of that most severe kind which fixes in the centre of the cheek: it came like a flash of lightning upon him. I exhausted my little store of remedies, and still he returned, not weekly but daily, a miserable object—a study for the painter, if he desired to design "the last man,"—a man despairing.

After some weeks of attendance, one morning (whilst I was surrounded with the out-patients) this man, not waiting his turn, burst through the crowd, calling out he was cured! This, no doubt, he did from his confidence in the interest young and old had taken in his sufferings. I knew not what I had given him, but on looking to his card, I found the following:—

℞ Ol. Tiglii. (Croton) gtt. j.; Mas. Pil. Colocynth. Co. ʒj. Misce et fiant. pil. xii. Mitte. Pil. Galban. Comp. xii. One of the purgative pills and two of the gum pills to be taken on going to bed.

The pills operated quickly, and rather violently, upon him; but he continued them; the pain leaving him, and a remarkable change taking place for the better in his countenance, no doubt from his obtaining sleep as well as freedom from pain.

Before I go further, I shall recal your attention to the pathology of this complaint, and venture to repeat what I formerly stated to you. It has appeared to me surprising that authors have omitted to found on the anatomy of the nerves, which leads so directly to the satisfactory explanation of the symptoms in this disease. The sympathetic nerve we have seen to be a whole system of nerves spreading every where, possessed neither of sensibility nor power over the voluntary muscles; it is nevertheless acknowledged to

have important offices in controlling and combining the whole economy of the system, and to have its centre in the abdominal viscera. The very circumstance of its affording no phenomena like other nerves, should lead us to conjecture that, as this system resembles in structure the nerves of sensibility and motion, it must have powerful, though secret, influences.

I was careful to point out to you that the connexions of this system, or (if you will) of this nerve, are universal; but that the habits or mode of demonstrating it, leads us to pay more attention to the branches which extend into the head, though neither larger, nor probably more important, than those which extend into the plexus of the axilla, or into the sacro-ischiatic nerve.

Are we to admit or to deny this influence of deranged bowels—of visceral irritation—in producing external pains, local paralysis, or partial spasms? No man who attends to disease can deny the existence of this influence. Taking this as admitted, the line of connexion is clearly laid down in the anatomy.

Nor can we deny, I think, the effect of the confluence and mixing of internal nerves with such as go to parts external and exquisitely sensible; and that, through this connexion, external pains become significant of internal disease, or more commonly of irritation and disordered function.

One step further in this inquiry. The fifth nerve is the most exquisitely sensitive of all the nerves of the frame: the sensibilities it bestows are enjoyed in a higher degree than those produced through any other nerve of the system. It is also the seat of most severe pain.

Impressed with these facts, the moment that we see the map of the relations of the sympathetic nerve with the second division of the fifth, by a large and direct branch, and lesser connexions of the same nerve with all the branches of the fifth, we surely need look no further in explanation of the frequent and intimate dependence of a painful affection of the face upon the state of the digestive organs.

It is rather remarkable that Mr. Abernethy, who did so much to direct the attention of the profession to the influence of the stomach and bowels on local affections, should have abandoned his ground on the occasion of the triumph of the principle. I allude to that passage of his work when he writes, "I shall only say, that to me tic douloureux appears, in general, to be as much a constitutional affection as gout, or rheumatism; and that constitutional treatment is that which seems most likely to be of advantage in this as well as in nervous affections generally."

Most certainly the mere exhibition of blue pill and the bitter draught (though they will alleviate) will not cure the painful affection of the great nerve of the face. But consider the length of the intestinal canal: above all consider how strangely distinct portions of that canal are affected by different medicines. Does not this imply a distinction in portions of the tube, which may, in their disturbed condition, affect remote parts, and with various effects? This, I confess, has long been my opinion; and that although the common means of relieving a headache, or a megrim or clavus, may fail in this, yet that we ought not to despair of finding a purgative which, peculiar in its properties and effects, may reach the seat of this irritation, and may consequently influence the tic douloureux; and what more likely than the croton, in proper combination? I was acting under this conviction when I prescribed the croton oil.

But let us return to the result of experience. Since the period when Delafield appeared suddenly among us, like him who drew Priam's curtain, I have had four cases of pure *tic*, cured by the same means.

The first instance was in the lady of the Rev. R. H., of Kent. She sent for me to the hotel; she described her sufferings, the nature of which I shall presently narrate. I prescribed for her, and took the precaution of recommending her to shew the prescription to her medical friend in the country, and to make him a party to the proceeding. After some time she returned to town, with the most animated expressions of the benefit she had received; and on Friday last I saw this lady's husband, who spoke only of the fear of the return of the disease.

I shall state a case almost within your own sphere of knowledge, since the lady was attended by Mr. Wood*, late house-surgeon, and who shews his regard for the old hospital by being occasionally with us:—

Mrs. W. came to Gordon's Hotel, to be under my care and Mr. Wood's. She looked miserably, being continually in dread of pain. The attack begins by a deep and agonizing pain on the right side of the nose or cheek; it then ranges to the back of the head and neck, returns through the roof of the mouth, and fixes in the place first affected (the canine tooth and lateral incisor tooth are exquisitely sensitive); and this is its course invariably. "The pain is periodical; it has not varied, in the time of its return, five minutes for eleven weeks. It attacks her at one o'clock in the morning, whether she be asleep or awake. Last

* Now practising in Bolton-Street.

Sunday night she sat up till one o'clock, to see if she could prevent it; but it came at the appointed time. It continues from one till eight, when it gradually abates; during all this time she cannot remain in bed, but walks about the room. The attack recommences at half-past ten in the morning."

In conjunction with Mr. Wood, I gave this great sufferer the combination of pills I have mentioned to you; and the report after three days was to the effect, that "the pain does not come on till three hours after the usual time of attack, which time she has gained for refreshing sleep."

She went for a week to the neighbourhood of Windsor; returned in a few days; resumed her pills, the ol. tiglii being increased to the sixth of a drop in each pill. She had also a comforting draught, with infusion of gentian and of cloves, with tincture of orange peel and spirit. ammon. aromat; and on my second visit after her return, I had the pleasure of seeing her in great spirits, and entirely free from pain.

On the 17th of this month I took this note of a lady's suffering from tic douloureux:—"She acknowledges to have bad health; she has weak digestion, flatulence, no acidity, but torpid bowels constitutionally, which obliges her to take a little pill. She thinks her complaint commenced from cold, caught in driving in an open carriage; it has continued fourteen weeks; it is a violent pain on the cheek-bone, in the eye, and in the temple. The pain is so violent and so sudden, that she compares it to what might be the effect of a blow with a hammer on the eye; it comes on whilst she is sitting at dinner; the eye pours out water. The pain usually continues from one till five in the afternoon. She is well at night, and passes the hours of sleep tranquilly; she has swallowed pounds of iron; has used veratria externally."

I hope to report favourably of this patient; having recommended her to continue under her excellent physician, with the hints as to medicine which I have given you. I need hardly add, that before these patients came to me, they had tried bark, steel, ammonia, arsenic, belladonna, and iodine, and all the usual remedies to correct digestion. The belladonna and blue pill was the medicine which the late Dr. Warren depended on. The external application which the last patient found to be most beneficial, was laudanum and obacco infusion.

Some have appeared to me to confound the disease of the nerve with the true tic; and I would preserve the name, to distinguish it from various other painful affections of the face, necessarily seated in the fifth, which is the only nerve that bestows sensation here. We have had in the hospital, patients suffering from excruciating pains of the face, from disease of the parts surrounding the nerve; and no doubt similar pains arise from disease of the bone; but you will have no difficulty in distinguishing the true tic, by the suddenness of its attack, by the perfect intermission, and more especially by the circumstance of the sensibility of the parts, and the action of the muscles, being unimpaired; whereas in those painful affections which arise from the actual presence of disease, there is numbness of the parts supplied by the branch of the fifth nerve which is affected; or the nature of the complaint is evinced by the inflammation spreading to the third nerve, and affecting the eye-lid.

I must not dismiss this subject without adverting to the opinion expressed in a work which is in your hands—the Lectures of Sir Astley Cooper, by Mr. Tyrrell. I allude to the passage where he describes the operation of dividing the branches of the fifth nerve; and not these only, but the portio dura of the seventh nerve, which is described as the most frequent seat of this disease. I wish Sir Astley Cooper had looked to this passage, and given it the guard of a note: nobody is better aware of the effect of the division of the portio dura, since I formerly told you that, directly on the publication of my first paper on the nerves, he furnished me with examples of the effect of cutting it across.

But the division of the branches of the fifth, though it has been practised by every surgeon of eminence in the last half century, is not to be copied. It produces only the effect of a severe impression; the advantage is temporary, if any, and the root of the evil is not reached.

The complaint the most likely to be mistaken for the true tic douloureux, is that pain felt on the superficial branch of the fifth consequent on disease of the bone or sockets of the teeth influencing an internal branch of that nerve. But this can be ascertained by careful observation.

On the whole, that disease which is marked by the sudden and violent pain—as, when a patient, in speaking to you, starts as if lightning had struck him, and applies his finger to his face and to the branches of the fifth pair of nerves, the infra-orbitary or superciliary holes, or angle of the eye, and when he remains thus holding his head, speechless, and rocking on his seat—such a pain will not be mistaken for the disease in the nerve: it is the true *tic*, as I must presume depending on remote irritation.

To sum up, I feel authorized to say,

that the tic douloureux is of that class of pains where the irritation of internal parts affects an external and sensitive nerve; where the disease is not actually seated in the nerve, but results from a remote irritation. Nor is it the consequence of disease embracing the trunk of the nerve affected; as in the patients from whom these preparations before me were taken. I feel equal confidence that the source of the disease is in the abdominal viscera—not arising from disease otherwise formidable, but rather from disordered function, which I apprehend to be the reason why patients suffer for a long succession of years unsubdued in strength, unless by watchfulness and the exhibition of poisonous medicines which are in vogue.

I have stated to you that I have had five cases in succession of painful affections of the face, varying considerably in their character: some where the pain shoots suddenly, and for a short period, and coming irregularly: others strictly periodical, and these cured by the very simple means I have told you; the sixth may be a failure. But these are sufficient to countenance the opinion I have offered; and that you are still to seek the means of relief by correcting the morbid condition of the viscera.

LECTURES

ON THE

DISEASES OF THE NERVOUS SYSTEM.

By M. Andral.

As published in the *Gazette des Hôpitaux*, with the approval of the learned Professor.

HÆMORRHAGE OF THE NERVOUS CENTRES.

Effects produced by Cerebral Hæmorrhage on Digestion—Circulation—Respiration—Secretion—Generation—Various Complications of Symptoms—Certain Rare Affection—Duration and Progress of Cerebral Hæmorrhage—Treatment of the Attack, and of the Symptoms which remain after—Prophylaxis.

We have next to pass in review the various affections which are produced in the functions of nutritive life, by hæmorrhage of the nervous centres.

Digestion presents no marked change except in complicated cases. I ought, however, to remark that there is constipation of greater or less obstinacy; but I already pointed out this while speaking of the muscles of the rectum, the contractility of which is diminished, or altogether abolished. The mucous membrane of the alimentary canal also becomes less sensible, and it is astonishing to witness how doses of purgatives are now borne, such as would under other circumstances have been inadmissible.

Even the *Circulation* offers nothing which is precise or constant, so that the state of the pulse admits of no general description. Sometimes, at the moment of the hæmorrhage occurring, it is strong and vibrating; at others, it is small, weak, and compressible. These characters of the pulse require great attention in reference to the treatment. Some remarkable circumstances have been observed with respect to the circulating system, and great importance has been attached to the condition of the vessels in the face, as indicating the serous or sanguineous form of the effusion. But this assumption does not hold good, for all those who have hæmorrhage of the brain have not redness or flushing of the face; on the contrary, some of them have the countenance remarkably pale. In sanguineous apoplexy, a certain degree of suffusion of the eye has been frequently observed; and, indeed, hæmorrhage into the brain has frequently been preceded by bleeding from the mucous membranes.

Respiration is not very notably affected where the cerebral hæmorrhage has been trifling: but this does not hold good with respect to the mesocephalon, however inconsiderable the hæmorrhage. The slightest lesion of this, or of the *tuber annulare*, produces an immediate and direct modification of the function of respiration. I do not find that any specific observations have been made with regard to the influence in these respects, of hæmorrhage into the cerebellum. I have said, that if the bleeding into the hemispheres be trifling, no modification of breathing is produced, but if it be considerable, this function may be impaired to as great an extent as in effusion into the mesocephalon or medulla oblongata.

Secretion—requires no comment, unless, indeed, it be that the urine is not voided with the usual facility, owing to the paralysis of the bladder, as I have already stated.

With regard to the *Generative organs*, it has long been remarked that erection takes place in certain hæmorrhages. No account was taken of this phenomenon, and it was confounded with what happens in strangulation; it was attributed to asphyxia and turgescence of the venous system, till Gall came, and placed the organs of generation under the influence of the cerebellum. Proceeding upon this idea, some persons have endeavoured to shew that erection always took place when the cerebellum was the seat of the effusion. What number of cases are there in support of this opinion? Seven instances have been published, in which erections were present

simultaneously with hæmorrhage of the cerebellum; but let me add, that such erections have also been met with in other cases, where there was no such hæmorrhage. In the seven cases alluded to it was the middle lobe which was affected. Six of the patients belonged to M. Serres, who has recorded them either in his Anatomy of the Brain, or in Magendie's Journal de Physiologie. The other case, related by M. Guyot, also presented hæmorrhage of the middle lobe. One of those related by M. Serres was very remarkable, inasmuch as a woman, 70 years of age, who had hæmorrhage of the middle lobe of the cerebellum, had the menses return at this advanced period of life; and at the time of her death had the uterus filled with blood, and the ovaries injected.

The preceding cases are unique, and for myself I have not found a single instance in which any affection of the genital organs has been coincident with hæmorrhage of the lateral lobes of the cerebellum. But frequently, when the middle lobe is diseased, the medulla oblongata in which it lies participates in the change in such manner as to render it very difficult to say from what point the symptoms originate. On the other hand, whilst there is paralysis as to sensation and motion in the limbs and other parts, the erection alluded to must be regarded as of a nature quite opposed to palsy. Besides, this erection is produced without any lesion of the cerebellum—as for instance, by certain inflammations of the spinal cord; and M. Segalas, by touching the spinal marrow at a particular point with a needle, was able to excite erections, and even emissions. Certain accidental productions, such as softening, &c. have sometimes produced some change about the genital organs; but at present I speak exclusively of hæmorrhage.

Complication of symptoms. — I shall here conclude what I have to say of the symptoms which usually attend hæmorrhage of the nervous centres. But these symptoms do not always present themselves with the marked characters I have described; they may also be complicated with other phenomena, or be replaced by symptoms altogether new, depending either upon affections of the cerebral mass, or of other parts, the lesions of which then become mixed up with those of the nervous system.

As to those complications which are connected with the nervous centres, they may present themselves in affections of the intellect or motion. Thus in some persons there are cramps, which are not to be regarded merely as produced by the effusion, but by the inflammation which surrounds it; at other times convulsions are observed, which come on at intervals, and affect only the paralyzed limbs. Sometimes, one side of the body being paralyzed, the other is a prey to convulsions; but these convulsions do not depend upon the effusion—they arise from the inflammation of the meninges in its neighbourhood. Are we to regard these convulsions as always depending on inflammation? When we bleed patients for apoplexy, we sometimes see frightful convulsions come on while the blood is flowing, so that we are obliged to tie up the arm again. In such cases the bleeding cannot have induced inflammation, and the convulsions are to be attributed to the too sudden abstraction of blood.

Certain other more rare effects. — I have two or three times seen individuals who, at a longer or shorter period before, had been affected with cerebral hæmorrhage, and who had ever since suffered from a singular necessity of walking directly forwards, this being occasionally interrupted by an imperative necessity of walking backwards,—the impulse in either case being inevitable. Either of the above modifications of motion may be present without the other. How are these curious facts to be explained? Magendie, in the course of his experiments, by cutting the part of the hemispheres behind the corpora striata, or by cutting these parts themselves, produced in various animals an irresistible necessity of moving forwards; if, on the other hand, he removed the cerebellum, the animals always ran back, as if seeking to avoid something which frightened them. Is there any thing analogous to these artificial lesions in the brains of apoplectic patients who present the same phenomena? Have lesions been found corresponding to these aberrations of motion? I do not think that any such cases, in man, are well authenticated, unless in one instance, wherein lesion of the cerebellum was found in a patient who always had a great tendency to walk backwards. As to the rest, this disposition to walk either backwards or forwards is extremely rare.

Sometimes the hæmorrhage has been found in one of the peduncles of the cerebellum. It is well known that, according to the experiments of the same professor, if those parts be cut in one of the lower animals, it begins to turn round and round till it be completely exhausted. Accordingly M. Serres found on the dead body of a patient who had shewn this tendency to wheel round and round, a hæmorrhage into the right peduncle: this case, so far as I know, is unique.

I have also said that there were some unwonted phenomena to be mentioned in reference to the intellect; that is to say, some which are wanting in the great majority of cases. Among these is a violent

delirium, which shews the presence of an inflammation of the brain or its meninges; and this may take place either on the first appearance of the hæmorrhage, or some days after the attack. A certain degree of dulness, or somnolence to a greater extent than I described under the general symptoms, may also be occasionally met with.

If we now turn our attention beyond the nervous centres, we shall find various acute or chronic inflammations taking place simultaneously with these hæmorrhages; and such inflammations present a character altogether peculiar, dependent upon the cerebral lesion. The most conspicuous circumstance is the tendency to adynamia, resulting from the compression, by which the vitality of the individual is altered. In such cases, sloughs form with great readiness on the points where the body rests for any considerable time.

Duration of hæmorrhage of the nervous centres.—This will vary according to the seat of the lesion. It rarely proves fatal at once; there is always some interval between the effusion and death—such as a quarter of an hour, one, two, three, four, five hours, &c. More usually the interval is yet longer; and when you see a person fall dead, as if shot, do not infer that it is a case of apoplexy, for this kind of death does not occur even from hæmorrhage of the mesocephalon: your suspicions ought rather to be directed to rupture of the heart, or great vessels. Sometimes, in such cases, nothing is met with, and then some vague hypothesis is created; but it is generally made in bad faith, or by persons who have not investigated the case sufficiently.

Progress.—Frequently, when it has once commenced, such a case makes constant progress one way or the other. Sometimes, from the attack till death, there is a succession of changes; the relapses are frequent, and it rarely happens that an individual who has once had an apoplectic stroke fails to die of the disease. The prognosis is therefore formidable in itself, and from the frequency and facility of relapses. As to the rest, the complaint presents great varieties, according to, 1st, its seat, which may be either in the mesocephalon, in the hemispheres, the cerebellum, or spinal marrow. 2dly, The nature of the symptoms: thus it may be with or without loss of intelligence; with or without various complications. 3dly, The intensity of the symptoms, which may be distinguished into weak, medium, and strong; and this old division is one which it is convenient to retain. 4thly, Upon the complications with other diseased states, which may take place either in the substance of the brain, or in the membranes, or in other organs.

Treatment.—The method of treatment may be distinguished into that to be adopted during the attacks, into that directed against the accidents which follow it, and into that intended to prevent a relapse.

1. During the attack the essential part of the treatment consists in the abstraction of blood, which ought to be had recourse to abundantly, both generally and locally, but particularly the former. From these we obtain a variety of effects: they present an obstacle to the continuance of the hæmorrhage, and they remove the congestions which have a tendency to take place all over the brain, and which, rather than the hæmorrhage itself, are the cause of death; they prevent inflammations, which otherwise become developed in a manner more or less speedy and violent. Besides all this, bleeding favours the re-absorption of the blood which has been effused. Some recommend opening the veins of the arm; others those of the neck; others those of the feet. Bleeding from these last is often difficult, and at all events it is usually easier to obtain blood, and to as great an extent as we please, from the arm. Magendie and some others recommended puncturing the occipital arteries. What is of most importance is to abstract a sufficient quantity; and we must not fear to take a pound: the English go even to the extent of two pounds at once.

But is it always necessary to have recourse to the abstraction of blood? I have found in my practice that it is so, and that two, three, or even four bleedings, are requisite; but if the symptoms do not then yield, and the patient becomes weak, the coma will only be increased by farther evacuation. I have seen some cases where nothing had been done, beyond applying a few leeches; and others, where only a clyster was administered; and yet the patients, after lying three days in a state of coma, recovered, all the symptoms disappearing, except the paralysis. This does not show that we ought not to bleed, but only that the state of coma may pass off without this remedy, and that bleeding, carried too far, may be productive of harm. The same holds good with respect to the inflammations of other organs, in all of which there is a point, beyond which bleeding fails to be of any service. In the pathological, as in the physiological condition, there is a certain period necessary to bring either a fatal or favourable termination. A certain degree of power is required by nature for accomplishing the breaking up and absorption of the clot: bleeding, practised judiciously, favours

this, but when carried too far, impedes it. If there be any one disease more than another in which nature makes an astonishing effort at reparation, it is in hæmorrhage of the brain. Bleeding from an artery has frequently been tried in these cases, and the effects have been much praised, especially in the temporal artery; but the facts are not sufficiently numerous, and I much prefer opening a vein. An American physician has practised arteriotomy at the wrist, in apoplexy, with success, but this does not seem to deserve imitation. Under particular circumstances, leeches may be applied to the thighs, the groins, or the anus. The head ought to be kept uncovered, and moistened occasionally with cold water, but the application of ice requires great caution.

It is necessary to act on the skin and the alimentary canal by medicines and clysters; but emetics, which were long erroneously regarded as useful, must be avoided.

Treatment of the sequelæ of apoplexy.—Have we the means of directly combating the paralysis? Certainly not, inasmuch as it is but a symptom. However, there is a period, long after the attack, when we think that all the clot has been absorbed, we may directly stimulate the paralytic limbs, or the nerves going to them; and what leads me to say so is, that cases have been met with in which individuals have died paralytic, long after the apoplectic seizure, in whom no lesion whatever has been found in the brain; or if any change, at all events this has been exceedingly slight. Under such circumstances the paralysis was doubtless perpetuated, merely because the patients had lost the habit of moving the limbs, and had made no effort to regain it. Electricity and nux vomica, employed too soon, may lead to a return of the hæmorrhage, and so cause the immediate death of the patient.

In old palsies it has been customary to try mineral waters of various kinds, and in various ways. Baths of all sorts are also used.

In those patients who shew a tendency to the adynamic form of disease, I find it useful to give them habitually some light tonic, as bitters, or steel,—directing my attention rather to the general system than to the head in particular. The means I have just mentioned restore to the system the degree of energy required for carrying on the absorption.

The *preservative* means consist in abstracting blood from time to time from those who exhibit signs of cerebral congestion. Without this condition the bleedings would be useless. The same remark also applies to various kinds of disease.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

February 18, 1836.

William Parker Hoare.
Arthur Noverre.
Charles Pickering.
John Dommett Bishop, Calne, Wilts.
James Robb, Ockbrook.
Thomas Prichard, Anglesea.
Thomas Norris, Wigan.
Henry Whittaker Baker, Ludlow.
George Smith, Bridlington.
Edward Headlam Greenhow, Tynemouth.

February 25.

Samuel Lamb, Stourport.
Samuel Nicholson, Manchester.
Thomas Young, F.L.S., Taunton.
C. H. M. Mules, Ilminster.
William Bingley Lamb, Wakefield.
John Field, Tong.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XXIII.

OF SULPHUR.

History, &c.—This substance must have been known at a very early period, though Stahl is the first who gave a definite value to the word *sulphur;* for the ancients used it to signify the general cause of combustibility, and, therefore, every combustible was said to contain it. By some this word is derived from *sal*, and *πυρ, fire;* by others, from *solum* and *πυρ*. Our common term, brimstone, seems to be a corruption of *brin* or *brenstone*, or, as Piers Ploughman writes it, *brynston*, and literally means *burning stone*.

Native state.—It is abundantly met with in nature, principally in the inorganic, but also in the organic kingdom. *Native*, or *virgin sulphur*, is found uncombined with any considerable portion of other ingredients, and is divided by mineralogists into *common* and *volcanic*. The first exists in the oldest rocks, namely, the inferior stratified ones (as mica slate), and the unstratified ones (as granite.) Volcanic sulphur abounds in the neighbourhood of volcanoes, of which it is one of the products. In the neighbourhood of Vesuvius there is a hill which has long been famous as a repository for this substance; I allude to Solfatara, denominated by the ancients *Forum Vulcani*, or the Court of Vulcan. It is a kind of half-extinct volcano, from which are constantly evolving sulphuretted hydrogen, muriatic acid, and aqueous vapour. (Fig. 92).

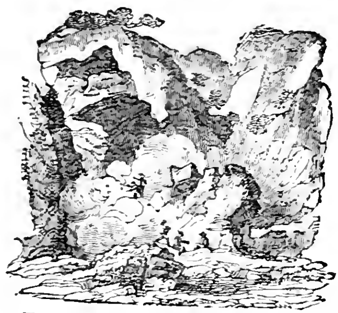

FIG. 92.—*Warm Spring of Solfatara.*

Sulphur is also found native in a state of combination. Thus sulphurous acid gas exists in considerable quantities near Ætna and Vesuvius; and sulphuric acid is found in the free state, as well as in combination, forming sulphates. Sulphuretted hydrogen, or hydrosulphuric acid, is developed from sulphureous waters, and from the soil in volcanic countries. Lastly, pyrites, or metallic sulphurets, are met with in great abundance: I need only instance the sulphurets of lead, copper, and iron.

Sulphur likewise exists in the organized kingdom; but I shall only cite garlic and eggs, as containing it.

Preparation.—It may be obtained in two ways,—by the decomposition of the native sulphurets, or by the purification of native sulphur.

(*a*) *Purification of native sulphur.*—To free native sulphur from its impurities, it is distilled in earthen pots (fig. 93, 1 1), arranged in two rows, in a large furnace; the top of the pot, which serves for the introduction of the sulphur, and for the removal of the residuum, being kept closed during the operation. The upper and lateral part of

each pot communicates with an inclined tube of about two inches diameter, and

Fig. 93.

four long. When the fire is lighted in the furnace, the sulphur fuses and sublimes, and passes through this tube into another pot (2), placed on the outside of the furnace, and perforated near its bottom to allow the melted sulphur to flow into a pail (3) containing water, where it congeals, and forms the rough or crude sulphur (*sulphur crudum*). This crude sulphur is further purified by distillation in large cast-iron vessels, and it then forms the *refined sulphur* of commerce. When fused, and cast into wooden moulds moistened by water, it constitutes the *stick*, *roll*, or *cane sulphur* (*sulphur in baculis*) of the shops.

For medicinal use it is reduced to a pulverent, or rather granular form, by sublimation from a large iron retort or pot into a chamber, or sulphur house. In this state it forms the *flowers of sulphur* (*flores sulphuris*), or *sublimed sulphur* (*sulphur sublimatum*). As a little acid is formed in the process, it requires washing, and then becomes *washed sulphur*, or *sulphur lotum* of the Pharmacopœia.

(*b*) *Decomposition of the metallic sulphurets.*—In some places sulphur is obtained by roasting or distilling the sulphurets of iron or copper. At the Paris mines in Anglesea, it is prepared by roasting copper pyrites; and the sulphur which is volatilized is collected in chambers, connected with the domes of the furnaces by means of horizontal flues. In Saxony and Bohemia, sulphur is obtained by distilling iron pyrites (*bisulphuret of iron*) in earthen tubes, placed in a long furnace or gallery. About one-fourth of the sulphur is disengaged by the heat, and passes into a receiver, where it is condensed in water; the residue is the sesqui-sulphuret of iron. The rough sulphur thus obtained is purified by fusion, which is sometimes twice or thrice repeated; the lighter impurities which rise to the top are skimmed off, and the liquid sulphur poured from the heavier sediment which falls to the bottom. The dregs remaining after the purification are called horse brimstone, or dregs of sulphur (*sulphur vivum*; *sulphur caballinum*; *sulphur griseum*.) This sulphur may be further purified by distillation, as mentioned in the last process.

Properties.—Pure sulphur is brittle, crystallizable, and, at common temperatures, solid; of a yellowish-green colour, without smell, and with a very weak and almost imperceptible taste. Its specific gravity is about 1·99. It is a bad conductor of electricity, and, therefore, by friction becomes powerfully electric. It is a bad conductor of heat, and when grasped in the warm hand crackles, and sometimes breaks to pieces. It is fusible and volatilizable; but the points at which these phenomena occur are variously stated. When heated to about 300°, in contact with atmospheric air, it takes fire and burns with a pale blue flame, and at the same time emits a large quantity of fumes having a peculiar suffocating odour (*sulphurous acid.*)

Sulphur is said to be a *dimorphous* substance; that is, the primary form of the crystals of native sulphur, or of those deposited from the solution of this substance in bisulphuret of carbon, is a rhombic octahedron; while that of the crystals obtained by the fusion and slow cooling of sulphur, is an oblique rhombic prism. Now these two forms are incompatible, and cannot be derived the one from the other: the first belongs to the *rectangular* or *rhombic right prismatic system*; the second to the *rectangular* or *rhombic oblique prismatic system*.

When sulphur is heated to 340°, it becomes viscid; and by increasing the heat the viscidity increases, until the temperature arrives at between 400° and 500°. If while in this state it be suddenly cooled, as by throwing it into water, it remains quite soft, so that it may be drawn out into threads. The cause of this change, which seems to be merely physical, is not understood. The atomic weight of sulphur is 16.

Characteristic tests.—Sulphur is easily distinguished from other bodies, by its colour, its fusibility, and its volatility, and by its burning with a blue flame, and the evolution of sulphurous acid gas, the odour of which can be easily recognised.

Impurities.—Rough sulphur is always mixed with variable quantities of foreign substances. Vauquelin distilled 200 grains, and obtained a residuum of 0·82, composed of silica, carbonate of lime, iron, bituminous charcoal, alumina, and magnesia, but the proportion of earthy matters is generally more considerable. Sulphur obtained from pyrites sometimes contains orpiment, (*sesqui sulphuret of arsenicum.*) The purity of any specimen is determinable by dissolving it in oil of turpentine, which does not act on the impurities.

Physiological effects.—In doses of one or

two drachms, sulphur acts as a very mild purgative, without exciting the vascular system, or occasioning griping. Given in smaller but repeated doses, it is said to operate as a stimulating diaphoretic. That it becomes absorbed is shown by the smell of sulphuretted hydrogen, which it communicates to the sweat, urine, and milk, and by silver articles in the pockets of patients, becoming blackened. Various ill consequences have been attributed to the continued employment of it. Thus it has been said to cause inflammation of the bowels; and in confirmation of this we are told, that in the Veterinary School at Lyons, it has been found that a pound of sulphur given to a horse brought on intestinal inflammation, and death. I know not what the effects on horses may be, but I believe it to be a very safe remedy for the human subject, and I say this from a somewhat extensive experience of its effects.

Uses.—Sulphur is employed both internally and externally.

(*a*) *Internally*—It is given for various purposes. *In affections of the rectum*, as stricture, hæmorrhoids, and prolapsus, it is a valuable agent as a mild purgative. I have frequently employed it when patients had great disgust for castor oil. In order to promote its purgative effect, it will be sometimes necessary to conjoin magnesia or the bitartrate of potash. *In chronic cutaneous diseases*, more especially prurigo, impetigo, and scabies, the internal use of sulphur is sometimes attended with great benefit. There are various other cases in which it has been recommended, such as chronic catarrh, asthma, gout, rheumatism, worms, &c.; but I think it is unnecessary to do more than allude to them. Some years ago it was proposed as a preventive against measles, though I believe the only real prophylactic is isolation.

(*b*) *Externally*—Sulphur is a most valuable remedy in various skin diseases, more especially seabies; and notwithstanding many substitutes have been proposed for it in the latter disease, none are so generally successful. Those who ascribe this disease to the presence of a small insect, the *acarus scabei*, explain the efficacy of sulphur frictions, by supposing that sulphur kills the little parasite. But before adopting hypotheses of this kind, first let the fact be proved that the itch is *caused* by an insect. It is unquestionably true, that in many persons affected with this disease, parasitic insects of peculiar characters have been found; but we have yet to learn whether these were causes, effects, or mere accompaniments of the cutaneous affection. Rayer says it is indubitable that the number of insects bear no proportion to that of the vesicles, and that it is rare to discover these insects on the abdomen and groin, although the eruption of scabies is here very common: moreover, he says, scabies is known to continue when no more acari are to be discovered.

Sulphur is also useful in various other chronic skin diseases, as porrigo.

Baths of the vapor of sulphur have been employed, according to Rayer, with advantage. Do not confound these with baths of the vapor of burning sulphur, that is, baths of sulphurous acid gas, which I shall notice hereafter.

Administration.—Internally it is usually given in the form of an electuary, or suspended in milk, in doses of from one to three or four drachms. The *lac sulphuris* is a more pleasant preparation for internal use than the sublimed sulphur. Externally sulphur is employed in the form of ointment. In the London Pharmacopœia are two sulphur ointments. The *unguentum sulphuris* is composed of three ounces of sublimed sulphur, and half a pound of lard. The other is the *unguentum sulphuris compositum;* it contains besides sulphur and lard, powder of white hellebore-root, nitre, and soft soap; but it is a very irritant application, and consequently is inapplicable in some cases. The great objection to sulphur frictions is their disgusting odour. The late Dr. Bateman recommends the following formula, as obviating "both the smell and sordid appearance of sulphur ointment:"

℞ Potassæ Subcarbonatis, ʒss.; Aquæ Rosæ, ℥j.; Hydrargyri Sulphureti Rubri, ʒj.; Olei Essent. Bergamot. ʒss.; Sulphuris Sublimati, Adipis Suillæ, aa. ℥ix. Misce secundum artem.

(*a*) *Precipitated Sulphur.*

History and synonymes.—This substance (called also *lac sulphuris*, milk of sulphur, and *hydrate of sulphur*) was known to Geber, the Arabian chemist.

Preparation.—Boil 1 part of sublimed sulphur with 2 parts of slacked lime in 8 parts of water. Filter, and add muriatic acid: sulphur is precipitated.

Theory.—The explanation of this process is very complicated. When sulphur and lime are boiled together, two salts are formed, namely, a bisulphuret of calcium, and hyposulphite of lime. The following formula will explain this part of the change:—

Re-agents.	Results.
6 S	2 (Ca + 2 S)
3 $\dot{Ca}$	$\dot{Ca}$ + (2 S + 2 O)

So that you see 6 atoms of sulphur react on 3 of lime, and generate 2 of the bisul-

phuret of calcium, and 1 of the hyposulphite of lime. On the addition of muriatic acid, both these salts are decomposed. By the action of 2 atoms of muriatic acid on 2 atoms of the bisulphuret of calcium, we obtain 2 atoms chloride of calcium, 2 of sulphur precipitated, and 2 of sulphuretted hydrogen.

Re-agents.	Results.
$2\,(Ca + 2\,S)$	$2\,Ca\,Chl$
$2\,H\,Chl$	$2\,S$
	$2\,S\,H$

1 atom of muriatic acid acting on 1 of the hyposulphite of lime, produces 1 atom of chloride of calcium, 1 of water, and 1 of hyposulphurous acid; which latter is immediately decomposed into 1 of precipitated sulphur and 1 of sulphurous acid.

Re-agents.	Results.
$\dot{Ca} + (2\,S + 2\,O)$	$Ca\,Chl$
$H\,Chl$	$\dot{H}$
	$2\,S + 2\,O \begin{cases} \ddot{S} \\ S \end{cases}$

Now the sulphuretted hydrogen (developed by the action of the muriatic acid on the bisulphuret of calcium), reacts on the sulphurous acid (formed by the spontaneous decomposition of the hyposulphurous acid), and forms water and sulphur.

Re-agents.	Results.
$\ddot{S}$	$2\,\dot{H}$
$2\,S\,H$	$2\,S$

However, from the smell, it is evident a portion of the sulphuretted hydrogen escapes unchanged.

Properties.—Precipitated sulphur agrees in most of its properties with sublimed sulphur, but is much whiter, and is in a finely pulverent form. Berzelius says, that when melted, it gives out a little sulphuretted hydrogen; and on cooling, resumes the yellow colour it had before boiling it with the alkali.

Composition.—It is composed of sulphur, with a little water; and hence it is frequently termed *hydrate of sulphur*. According to Bucholz, however, when well dried, it contains hardly a trace of water, and, therefore, any present under ordinary circumstances must be regarded as hygroscopic; so that the term hydrate is hardly applicable to it.

Impurities.—If sulphuric be substituted for muriatic acid, in the manufacture of this substance, sulphate of lime will be formed, and mixed with the precipitated sulphur. The impurity may be detected by volatilizing the sulphur in a crucible, or by solution in oil of turpentine or liquor potassæ.

The *effects*, *uses*, and *doses*, are the same as the common sublimed sulphur already noticed.

(*b*) *Sulphuretted Oil.*

History.— Sulphur is soluble in both volatile and fixed oils, and formulæ are still found in some continental works for the preparation of pharmaceutical compounds of them. The present is the only solution of sulphur contained in the London Pharmacopœia. It was formerly denominated *balsam of sulphur*.

Preparation.—It is prepared by boiling together two ounces of washed sulphur and a pint of olive oil. It cannot be regarded as a mere solution of sulphur in oil, since the odour of sulphuretted hydrogen which the compound possesses proves that the oil has undergone partial decomposition; in fact, the heat to which the oil is raised, to boil it, causes a chemical change.

Properties.—It is a dark reddish-brown viscid substance, having an extremely unpleasant odour.

Effects.—Locally it acts as an acrid irritating substance. Its remote action is that of a stimulant, causing thirst and febrile disorders. It has been supposed to possess expectorant and diaphoretic properties.

Uses.—It has been used as a local application to foul ulcers. For internal use, it is resorted to in pulmonary affections. Its unpleasant taste and smell in most cases preclude its employment.

The *dose* is from 10 to 40 or 50 drops.

Carbon.

History.—The term carbon, (from *carbo*, coal), was first employed by Morveau, Lavoisier, and Berthollet, to designate the pure matter of charcoal. To Lavoisier we are indebted for proving that by combustion in oxygen gas, the diamond and charcoal furnish the same product—namely, carbonic acid.

Native state.—Carbon is copiously met with in nature. When pure and crystallized, it forms the diamond: combined with oxygen, it constitutes carbonic acid, which is found in the atmosphere, in certain mineral waters, and in combination with bases (as lime): it occurs combined with hydrogen, either as carburetted hydrogen gas, or as bitumen: graphite or plumbago (which is carbon usually mixed with iron), is also a native form of carbon: lastly, carbon is a constituent of all organic compounds.

Properties.—It is solid, infusible, and not volatile. By combustion in oxygen gas, it

produces carbonic acid. Its other properties are so different, that three varieties of it are made:—

(*a*) The *diamond*.

(*b*) *Plumbago* or *graphite*, used on the continent as a medicine.

(*c*) *Charcoal*, also used in medicine.

(*a*) *Plumbago.*

History, &c.—The substance denominated *plumbago*, *graphite*, or *black lead*, was formerly regarded as a chemical compound of carbon and iron, and accordingly was denominated *percarburet of iron;* but the quantity of iron present is subject to great variation, and in some specimens from the Brazils there is hardly any, so that the iron is now regarded as an accidental substance. The finest specimens are brought from Borrowdale, in Cumberland.

Characteristics.—It is known by its physical characters, and by yielding carbonic acid when burned in oxygen gas. Sulphuret of molybdenum very closely resembles plumbago in appearance.

Physiological effects.—Various properties have been assigned to it, but further evidence is wanting to establish its action on the body.

Uses.—It has been employed both externally and internally in chronic diseases of the skin, such as herpes. When used externally, it is mixed with lard or some other fatty body. Internally, it has been given in doses of 12 grains to a drachm.

(*b*) *Charcoal.*

History.—More than three hundred years before Christ, Theophrastus described the method of making charcoal.

Preparation.—*Vegetable* charcoal is procured by burning billet wood, piled up in conical heaps, which are covered with turf and sand, to prevent the access of the atmosphere, a few holes being left near the bottom, and one at the top, to occasion a draft. *Animal* charcoal is obtained by distilling bones or ivory in iron stills: it contains phosphate and carbonate of lime, from which it may be freed by washing with dilute muriatic acid.

Properties.—It is black, inodorous, insipid, and brittle: a good conductor of electricity, but a bad one of heat; it absorbs various gases without effecting any chemical changes on them, except in some particular instances. One volume of boxwood charcoal can condense within its pores 90 volumes of ammoniacal gas, but only $1\frac{1}{2}$ volumes of hydrogen gas. Another remarkable property of charcoal is that of removing the colour of various animal and vegetable infusions; an effect which is commonly said to be of a mechanical nature, but an experiment made by Bussy would seem to prove that the colouring matter and charcoal enter into chemical union; the colouring matter acting the part of a feeble acid, the charcoal that of a weak base. The best kind of charcoal for decolorizing is that obtained from animal matters; and therefore, for all ordinary purposes, *bone black* (called in the shops *ivory black*) will answer the purpose. Charcoal absorbs organic odorous matters, thus destroying the odour of putrefying or rancid substances; but in this respect it is far inferior to chlorine and the chlorides.

Characteristics.—Charcoal is known by its combustibility in oxygen gas, the product being carbonic acid; and by its physical properties. The form or texture of charcoal varies with that of the substance from which it has been obtained.

Physiological effects.—Charcoal is, I believe, an inert substance; for Burdin has given a pound of it daily, without any other obvious effect being produced than the blackening of the stools. A variety of properties and virtues have been ascribed to it, as I believe, without foundation. It has been called anodyne, emmenagogue, tonic, purgative, &c.

Uses.—In this country, charcoal is used as a therapeutic agent, principally as an antiseptic, to absorb the fœtid odour evolved by gangrenous and phagedenic ulcers. For this purpose it may be used in the form of powder or of poultice. Its disinfecting and antiseptic powers, however, are much inferior to those of chlorine, or of the chloride of lime. As a tooth-powder it is a valuable agent, freeing the teeth from the foreign matters which cover them, and at the same time counteracting the unpleasant smell of the breath arising from decayed teeth or disordered stomach. Brachet states that it checks caries of the teeth. Internally it has been exhibited in various affections of the alimentary canal, such as dyspepsia, cardialgia, diarrhœa, and dysentery. The beneficial effects said to have been produced in these cases, can only be referred to the action of charcoal on the secretions of the bowels; an explanation apparently supported by Dr. Chapman's statement, that in dysentery, where the stools are highly acrid and offensive, charcoal entirely divests them of their bad smell and acrimony. In consequence of the advantage said to have been obtained by Dr. Calcagno, of Sicily, by the use of charcoal in intermittents, it was tried by Dr. Calvert, physician to the British forces at Palermo, and with success. In this country, however, it is, I believe, never resorted to in ague by medical practitioners. Charcoal has been recommended in various other diseases, but experience has not confirmed its efficacy.

Application.—In the Dublin Pharmacopœia there is a formula for a *charcoal cataplasm;* the simplest mode of preparing it is to mix charcoal with a common linseed-meal poultice: it is applied to foul ulcers, to destroy the odour.

PHOSPHORUS.

History.—This substance was discovered in 1669, by Brandt, an alchymist at Hamburgh; and received its name from being luminous in the dark (from φως, light; and φορεω, I carry).

Native state.—It is found in both kingdoms of nature, generally in the form of a phosphate. It is a constituent of the cerebral substance, and a French chemist some little time since asserted, that in madmen there is an excess—in fools, a deficiency of it!

Prepared.—It is prepared from bone ashes *(phosphate of lime),* by digesting them in sulphuric acid; by which sulphate and superphosphate of lime are procured. The latter is distilled with charcoal, which abstracts the oxygen from the phosphoric acid of the superphosphate, setting free the phosphorus, which is volatilized.

Properties.—It is a pale yellow, semi-transparent, crystallizable solid. Mitscherlich says the cystals are rhombic dodecahedrons; so that they belong to the regular or tessular system.

Characteristic tests.—Phosphorus in substance is easily recognized by the following characters: its waxy appearance, fuming in the air, being phosphorescent or luminous in the dark, and, by friction or gentle heat, causing it to inflame, and, lastly, by its burning with a most intense white light and smoke of phosphoric acid. A solution of phosphorus in oil, æther, or alcohol, may be known by its garlicky odour, and when rubbed on the skin, rendering the latter luminous in the dark.

Physiological effects.—Phosphorus ranks among the irritant and corrosive poisons. According to Orfila, its activity depends on its absorbing oxygen, and thus becoming converted into an acid which acts as a corrosive poison, like the other mineral acids. Hence, therefore, ætherial and oleaginous solutions are more active poisons, inasmuch as the oxidation of the phosphorus is effected more rapidly. On man it also acts as a poison; and in Dr. Christison's work you will find references to several cases: in one, $1\frac{1}{2}$ grain, in another instance, 3 grains, caused death. Cases, however, are reported, in which 6, 10, 12 grains have been swallowed without any hurtful effect; but doubts have been entertained as to the correctness of the statements. Thus the authors of the *Dictionnaire de Matière Médica'e* think the phosphorus employed must have undergone some chemical change. I once administered 16 grains of phosphorus to a man, without any hurtful effect; and judging from its physical characters, I should say the phosphorus was that usually met with in commerce. The man here alluded to was Chabert, some years ago renowned in London under the name of the "*Fire King.*" I carefully weighed out 16 grains, placed them in a spoon, and put them in his mouth; and he washed them down with a tumblerful of water. He offered to take this dose daily. How he counteracted the effects, I know not; but I suspect he excited vomiting, for within ten minutes after swallowing the phosphorus, he left the room for about a quarter of an hour.

Administered in small doses, it is regarded as a stimulating substance, exciting the nervous, vascular, and secreting organs. It has more particularly been supposed to stimulate the sexual organs, and to act as an aphrodisiac.

Phosphorus becomes absorbed. When a solution of it in oil is injected into the jugular vein of a dog, or into the pleura, white vapours of phosphorous acid are evolved from the mouth, and death shortly takes place; in consequence, as Orfila imagines, of the phosphorus absorbing oxygen, and, in passing through the pulmonary vessels, exciting almost instantaneous inflammation.

Uses.—Internally it has been employed in typhus fever; in some chronic diseases of the nervous system, as epilepsy, paralysis, melancholy, amaurosis, &c.; in cholera; in dropsy, &c. When resorted to now, it is more frequently as an aphrodisiac.

Administration.—Internally it is exhibited either in substance, or dissolved in oil or æther. But I believe the safest plan is to dissolve it in oil, and then make the oily solution into an emulsion, by mucilage. Thus digest for several days, one part of phosphorus, cut in pieces, in sixteen parts of olive or almond oil. A solution is thus obtained, which may be given in doses of from 15 to 30 drops, in mucilage or other convenient vehicle. This same oil, mixed with lard, may also serve for external use.

Antidotes.—Our objects are to stop the oxidation of the phosphorus, and to neutralize the resulting acid as fast as it is formed. To attain the first of these indications, give large quantities of mild demulcent liquids, so as to envelop the phosphorus and exclude it from the air. Magnesia is to be exhibited, with the view of neutralizing the resulting acid of phosphorus. Parts burned with phosphorus are to be washed with a weak alkaline solution, to remove any adhering acid which might serve to keep up irritation.

THE PHYSICAL DIAGNOSIS OF DISEASES OF THE VALVES OF THE HEART, &c.

Read to the Harveian Society, Feb. 1st,

By Charles J. B. Williams, M.D. F.R.S. &c.

President of the Society.

Few departments of practical medicine have derived more improvement from modern pathology than that relating to diseases of the heart. Yet I apprehend there are few who have had much experience in the theoretical and practical study of this subject, who will not in candour admit that our knowledge of it is still in an imperfect state, and that what we already know should serve as a basis for future researches, rather than satisfy us with its present sufficiency. The now acknowledged frequency of idiopathic affections of the heart, is in itself a sufficient reason for our making their signs a matter of prominent importance; and the considerable progress which has been already made in the diagnosis of these affections has compensated for the labours by which this knowledge has been obtained. But we should unduly limit the value of the physical signs of affections of the heart, if we confine their utility only to those which are idiopathic. These signs are constituted by the physical properties of the heart and arteries, as exhibited in the performance of their functions; and when these properties are changed by other causes in the system, besides those which primarily or exclusively affect the heart and arteries themselves, these signs will be also changed in proportion. Now although it is not professed that the diversified modifications which the function of the circulation undergoes in the various diseases of the body in which it is affected, have all their distinctive signs, yet I may venture to say, that by the physical exploration of the heart and arteries, in addition to feeling the pulse (this being itself also a physical sign), we may often obtain a much more accurate knowledge of the state of the circulation than can be gained in any other way; and this knowledge is sometimes immediately useful in elucidating the pathology of the case, and in suggesting the appropriate line of treatment.

But this field, though rich in promise, has scarcely yet been entered; and my reason for naming the subject is the hope of inducing others to assist in its cultivation. If any one accustomed to auscultation will take the trouble to examine half a dozen patients of different constitutions, and labouring under various complaints, especially those of opposite states, the sthenic and asthenic, cachectic and plethoric, nervous and inflammatory, he will find in the character, proportion, and degree of loudness of the sounds of the heart—in the nature and extent of the impulse, both of the heart and of the arteries—and in the interval between the ventricular systole and the radial pulse—he will find in these such marked differences as will convince him of the existence of particular physical signs, and further study and observation will teach him the value of these signs in the diagnosis and treatment of diseases, when their other characters are deficient or equivocal. To introduce illustrations of this position now, would be premature, inasmuch as the simpler diagnostics of flagrant organic disease of the heart, are by no means generally appreciated; but in commending to the attention of the Society the utility of auscultation of the heart in general, I could not resist the opportunity of enhancing the commendation by pointing to further advantages, which I hope will ere long be fully developed and acknowledged.

To the successful study of the pathology of the heart's condition and function, a knowledge of its physiological state and phenomena is essentially necessary. The cases which I have now to submit to the attention of the Society, are meant chiefly to illustrate the views which I have elsewhere advanced with regard to the healthy and morbid sounds of the heart*. Even on these common forms of valvular disease, ideas more precise than those commonly expressed in published cases and hospital reports, must be entertained, before their more prominent signs can prove truly characteristic: and until greater distinctness and accuracy on the essential points be observed, the cases become

* The Pathology and Diagnosis of Diseases of the Chest, &c. 3d Edit. Part III.

but imperfect facts, encumbering rather than improving the history of the subject.

It might, at first sight, appear of little consequence to be able to distinguish between the different forms of valvular disease, since the general character and treatment of all much resemble each other; but this is less the case than is generally supposed, particularly in the earlier stages of organic lesions of the valves; and the utility of the distinction is still more apparent in the fact, that without a knowledge of it, we shall often be unable to discriminate between organic and functional disease, and between the signs of old structural lesions, and some of the characteristic indications of incipient pericarditis. For example, the leather-creak of pericarditis often resembles certain valvular murmurs, and sometimes they are only to be distinguished from it by a full knowledge of those characters which distinguish one valvular murmur from another. The following cases, which occurred chiefly at St. George's Hospital, will illustrate the only physical signs that I have hitherto found distinctive.

Diseases of the Aortic Valves.

Wm. Watson, æt. 45, labourer; a patient at St. George's Hospital, November 9th —Has been rheumatic and had palpitation for more than six years. Suffers now from severe palpitation on ascent or quick movement, from cough, dyspnœa in paroxysms, and great sickness. For the last five or six weeks his legs have been swelled. He is also occasionally attacked with severe angina, which generally attacks at night. Pulse now 72, full and thrilling, but regular.

A double sawing murmur accompanies the pulsations of the heart. The first sawing, accompanying the impulse, is loudest and harshest at the top of the sternum, is deeper below this and to the left; it is heard also in the carotids. A whizzing murmur is heard, instead of the natural second sound, most distinct at the lower end and to the left of the sternum. Both murmurs are slightly audible in the back. Impulse of the heart diffused.

Diagnosis, written November 12th.* — *Obstructive and regurgitant disease of the aortic valves; probably diseased coats of ascending aorta. Heart enlarged.* Perhaps disease of the pulmonary valves (?).

November 26th.—Died suddenly in the water-closet.

Sectio. — Nov. 28th. — Some bloody fluid in the pericardium. Heart much enlarged, especially the left ventricle, whose walls were an inch thick, and cavity double the natural size. Aortic orifice ossified at the roots of the valves. The free margins of two aortic valves much thickened and shortened; that of the third less so; they could not nearly close the orifice. Ascending aorta somewhat dilated, and studded with fibro-cartilaginous deposit, in some of which were osseous laminæ. One large one projected from the origin of the coronary artery, and must have been directly in the current from the heart. The other valves were healthy.

John Hetcher, a patient of Dr. Macleod, June 30th.—Reports that he was quite well until nine weeks ago, when, after exposure to cold when heated by violent exertion, he had cold chills and general pains, especially across the chest; for which he was bled. Ever since, his breath has been short, with dyspnœa and occasional hæmoptysis. Legs much swelled. Liver large. He is subject to bilious vomiting.

The whole cardiac region dull on percussion, on and to left of the sternum. A loud double sawing was heard instead of the natural sounds, and was most distinct, with pulsation, at the top of the sternum. It was heard also in the carotids.

Diagnosis, written June 30th.—*Regurgitant disease of the aortic valves; probably dilatation of the arch of the aorta.* (Query, disease of the pulmonary valves?) The extent of dulness on percussion led me to suspect also effusion in the pericardium.

July 2d.—In a fit of palpitation, the heart acting violently, and pulse in carotids tumultuous. Each pulsation consists of a first impulse with sawing sound, then a second sawing, then a second impulse with a short sound; there is then a short interval. The pulse at the wrist is feeble, with a second weaker intermediate beat, corresponding with the second impulse of the heart. This double pulsation seems to depend on the regurgitation from the aorta, which causes the second sawing, stimulating the heart to a second con-

* The diagnoses mentioned in these cases were communicated, at the time, to several pupils and others present.

traction. This paroxysm subsided suddenly, and the pulsations became simple and regular, though quick, and still attended with the to-and-fro sawing, without any of the natural sounds.

July 6th.—A pulsation in the jugular veins, especially the right. Add to the diagnosis, *dilatation of the right ventricle.* Died the next day.

Sectio, July 8th.—Great œdema of the lower extremities up to the abdomen. Heart more than double its usual size, and presenting a flat surface four or five inches long, and three inches wide, in contact with the anterior parietes of the chest. (Hence the dulness on percussion.) Right ventricle and auricle much dilated; the parietes of the latter very thin. Right auriculo-ventricular orifice admitted three fingers. Membranous centres of tricuspid valve thickened, with a yellow deposit, not so hard as cartilage. Left ventricle dilated to nearly three times its ordinary capacity; its parietes at apex $\frac{1}{2}$ an inch, at base $1\frac{1}{4}$ inch thick. Columnæ carneæ greatly enlarged, and contrasted remarkably with the thread-like cordæ tendineæ, which seemed more slender than natural. The membranous portions and margins of the mitral valve thickened with a substance almost cartilaginous, but were large and mobile, and seemed sufficient to close their orifice. Aortic orifice more than three inches in circumference at the root of the valves, one of which was large, the other two considerably smaller, and must have permitted regurgitation. All were thickened, and on the large one were two short projecting bodies, of the same fibro-cartilaginous material that thickened the valves. Aorta greatly dilated from its origin to the commencement of descending portion: its coats thickened and puckered with several osseous scales, some of which protruded slightly into the artery. The pulmonary valves were thin, and as large as the largest of the aortic valves, and seemed quite sufficient to close the orifice, which was $2\frac{3}{4}$ inches in internal circumference. There were some spots of pulmonary apoplexy in the lungs.

William Gregory, æt. 36, shoemaker, a patient of Dr. Chambers.

Dec. 1.—Says that he was quite well till about eleven weeks ago, when he was attacked with a bad cough, shortness of breath, and some pain in the chest, which have continued.

Dec. 3d.—Expectoration deeply tinged with blood; legs swelled; pulse 96, full, and strong, but immediately receding under the finger; impulse of the heart diffused, not abrupt. A double sawing sound, loudest at the middle of the sternum, accompanies systole and diastole of the ventricles. The first sawing is heard in the carotid and subclavian arteries, where it is short, hoarse, and deep; the second sawing, superficial and whiffing, at the middle and to the right of the sternum; the natural second sound (flap) scarcely if at all heard.

Diagnosis, written Dec. 3d.—*Regurgitant and obstructive disease of the aortic valves; probably diseased ascending aorta* (dilated?); *hypertrophy and dilatation (?) of left ventricle.*

Dec. 7th.—Pulsations now irregular, every third beat being earlier and slighter. The sounds are now triple, there being a third, like the first, but shorter; (a second systolic action excited by the regurgitation from the aorta, as in the case of Hetcher).

Breathing became more and more difficult, and he died on the 14th.

Sectio, Dec. 16th.—A whitish red spot of lymph on the apex of the heart, under the pericardial covering; the muscular fibre there darker in colour. Left ventricle hypertrophied, an inch thick in parts, at apex three-quarters of an inch; its cavity rather smaller than natural, but elongated. The aortic valves were much diseased. The free margin of one, and of a portion of another, had become separated from their bodies, and formed a cord across the mouth of the aorta. The membranous portions, which ought to have been attached to this margin, were forced back into the ventricle, and afforded free passage to the blood backwards. These broken portions were ragged, very frangible, and elongated with soft red vegetations; one portion contained an osseous concretion. The root of the broken valve was also partially forced back into the ventricle, the two inner coats of its sinus having given way, so that an aneurismal pouch would soon have been formed there. The other valve remained attached; its arterial surface was smooth, and its sinus somewhat dilated; but it was much thickened, and covered with soft reddish vegetations on its ventricular surface, and similar depositions extended also over the membranous portion of the ventri-

cular surface of the mitral valve, which was otherwise healthy, and appeared to close well its orifice. In the ascending aorta (which was not dilated) there was some of the common deposition (miscalled atheromatous); there was some also at the arch, with two small osseous spiculæ, which formed slight projections from the surface. At the mouth of the innominata were two roundish laminæ of bone. Around these osseous depositions, as well as around the vegetations of the valves, there was a margin of redness in parts which could not be washed off. Pulmonary valves healthy; so were the tricuspid, but thin. Auricles and right ventricle natural. About eight ounces of bloody serum in the right pleura. The lungs were engorged, and in the right was an apoplectic spot. A white hardish degeneration, as large as a French bean, in one kidney.

In the three preceding cases, the diagnosis was pretty exactly verified by *post-mortem* inspection. The sonorous passage of the blood through the altered aortic orifice and tube constituted the murmur accompanying the systole, audible at the top of the sternum and in the carotids, as well as in the region of the heart. The second murmur, more or less whiffing, heard *instead of* the *flap* constituting the natural second sound, indicated a reflux of blood through the insufficient aortic valves into the left ventricle at its diastole. These cases, therefore, confirm the rules which I have given for the detection of diseased aortic valves, in my work on the Diseases of the Chest *. The only exception to this is in the complete absence of the natural second sound, although the pulmonary valves were healthy. I explain this circumstance by the constantly distended state in which the right cavities of the heart must have been kept in consequence of the insufficient propelling power of the left apparatus: this distention prevented the valves from flapping back with sufficient force to be audible. It is, therefore, useful to bear in mind that, although my experiments prove that the second sound is generally produced in both sets of semilunar valves, regurgitant disease in only one set, the aortic, may in some cases entirely supersede this sound. I have, however, also met with cases in which, besides the to-and-fro sawing indicating disease of the aortic valves, the natural double sound, with the second flap, was still audible to the right of the sternum, being produced in the right ventricle and pulmonary valves.

Elizabeth Holland, æt. 26, Dec. 24, a patient of Dr. Macleod, had rheumatism two years ago, since which has had dyspnœa and palpitation on exertion. Has become much worse for the last 11 days, with oppressed breathing, and pain below the left mamma; countenance pale and anxious; orthopnœa; pulse quick, and rather sharp, but regular. Both sounds of the heart heard well, with a sharp impulse below the left mamma. A rough bellows murmur with the first sound, heard best at top, and to left of sternum; heard also in carotids and subclavians, and in the left inframammary region, where it loses its roughness; it is less audible to the right of the sternum, where the double natural sound is very distinct.

Diagnosis given, Dec. 24.—*Disease of the aortic valves.* The general signs made Dr. Macleod and myself conclude that there was recent pericarditis. The distinctness of the sounds and impulse discountenanced the supposition that there was liquid in the pericardium, and the absence of the leather-creak, or sound of friction, rendered it probable that the inflammation had attacked the pericardium already adherent to the heart.

Sectio, Dec. 26, 12 hours after death.—Pericardium closely adherent, and could with difficulty be torn from the heart; the united membranes thickened, and very red; no recent lymph; heart about the usual size; aortic valves quite thin at the free margins, and perforated with several smooth oval holes, four in one valve, and two in each of the others. That with four was moreover very thin and elongated, the corpus arantii, with its thickening or hem, being 1-4th of an inch within its free margin, which was extremely thin. The smaller portion of the mitral valve was little more than a fringe: the other portion somewhat thickened, with cordæ tendineæ inserted on the whole of its ventricular surface, but it seemed sufficient to close the orifice, which was small. There were three small perforations also in the pulmonary valves.

* Page 197, *op. cit.*

No doubt the perforated state of the aortic valves acted as so many loops, catching the current from the heart, which was unduly excited by the pericardial inflammation, and thus caused the rough bellows sound.

These holes must have admitted of regurgitation from the artery at the ventricular systole, but in jets too small to produce sound. I suspect that such perforations of the arterial valves are not very uncommon, for during the last twelve months I have met with them in six cases, in all of which they would have been overlooked without more care than that usually bestowed on post-mortem examinations of the heart. In two of these cases there had been no symptoms of disease of the heart; and there was found besides no other change in the organ, except the remarkable shortness of the smaller portion of the mitral valve, which I shall have to notice further on. In another case there was also universal adhesion of the pericardium, and in two others, thickening of the mitral valve. These perforations are generally accompanied by a remarkably thin, atrophied state of the valves, and they are always roundish or oval, with perfectly smooth and somewhat thickened margins. I am inclined to think that they are allied in character to the shortened conditions of the mitral and tricuspid valves, to be noticed hereafter.

Diseases of the Mitral Valve.

A. C., æt. 22, nursemaid. Has had short breath, palpitation, dry cough, and pain in chest and head for the last three months; before which she lived in the country, and was quite well. Pulse now regular, but rather quick; a bellows murmur with first sound, heard best below left mamma; not heard in the arteries; catamenia regular, but scanty. Was somewhat relieved by acting on the secretions, regulating the diet, and enjoining tranquillity. The bellows murmur with first sound still continued: it was slightly audible in the back. Dimensions of the heart apparently not increased.

About two months afterwards she was attacked with bilious fever; pulse from 120 to 160, sometimes irregular; occasionally violent palpitation, with still the same bellows murmur; at times delirious; skin very hot; tongue brown, and furred. She was treated with calomel every three hours; leeches and ice to the head; leeches to epigastrium; saline draughts, &c.

The fever went on for a fortnight, when it gradually abated, tongue having become clean, skin cool, pulse more moderate, and dilirium gone; but there was still occasional palpitation, with a feeling of sinking; and one night she was attacked with sudden cough and dyspnœa, and died in a few minutes.

Sectio.—Lungs universally crepitant and healthy, but bronchi filled with frothy mucus; pericardium very thin and transparent; heart rather small, but walls and cavities well proportioned. It showed no other disease than a remarkable thinness and shortness of the membranous portions of the mitral valve, so that they could not have closed the orifice. Cordæ tendineæ fewer than usual, but their muscular pillars were very large. Intestines remarkably thin and pale; slight redness of mucous membrane of duodenum; the rest healthy.

I have reason to believe that shortening or wasting of the membranous portions of the mitral and tricuspid valves is by no means uncommon; and I have often found slighter degrees of it in cases where the heart had manifested no morbid symptoms during life. The smaller or posterior segment of the mitral valve is often little more than a fringe to which the cordæ tendineæ are attached; and unless there be at the same time a shortening or rigidity of these cords, or an enlargement of the auriculo ventricular orifice, it does not appear that much regurgitation ensues from this condition of the valve*. It is where the anterior or larger portion is shortened, stiffened, corrugated, or otherwise rendered unfit, or especially where, the tendinous cords being thickened and shortened, the valve cannot fall back close to its fellow, here regurgitation will accompany the systole of the ventricle, and if this be with sufficient force, it will be marked by the characteristic deep bellows murmur, heard below the left mamma, and in the other parts of the region of the heart, and not heard in the great arteries.

Charles Foster, æt. 25, gardener, a

* The best mode of opening the heart to display the ventricles and their valves, is to cut from the apex nearly to the base at right angles with the plane of the septum. If this be done accurately, the incision will expose the valves *in situ*, without severing the tendinous cords.

patient of Dr. Seymour, has been subject to rheumatism for four years. At his first attack he had palpitation, and was cupped on the chest. Has felt his breath short for only six weeks past, during which time his legs have become œdematous, and face puffy.

Pulse now regular and pretty strong. A bellows murmur, with the first sound, heard best an inch below left mamma; not heard at top of the sternum, nor in the carotids. Impulse diffused, and rather abrupt; region of heart more dull than usual on percussion.

Diagnosis, written about the end of October.—*Regurgitant disease of the mitral: dilatation with hypertrophy.*

Nov. 24th.—Had somewhat improved, but is again worse, and is now expectorating red viscid sputa (peripneumonic). Died on the 26th.

Sectio, Nov. 27th.—Heart much dilated, with some hypertrophy; no adhesion of pericardium; cordæ tendineæ of mitral valve thickened and shortened; the orifice dilated, so that it could not be closed by any position of the valve. Left auricle much dilated; a small vegetation on one of the aortic valves; the rest natural. The right lung inflamed in the first and second stages.

William Cooper, æt. 42, footman, a patient of Dr. Seymour, has had rheumatism occasionally from boyhood; and at the age of 20 suffered greatly from it. For the last two years his breath has been very short, with palpitation on exertion. These symptoms have much increased in the last five weeks, and he often wakes suddenly with a feeling of oppression and palpitation.

Dec. 15th.—Pulse very weak, irregular, and intermitting; pulsations of the heart from 140 to 160,—every fifth beat delayed, and many not propagated to the wrist; impulse felt most in epigastrium; diffused and indistinct on left side. Sounds weak; the first short, distinct, and somewhat rough, as if accompanied by a brief filing; the second weak, not audible in all pulsations.

Diagnosis in this case doubtful, on account of the quickness and weakness of the heart's actions, which were scarcely enough to cause a characteristic murmur; but all the signs rendered it probable that both sets of valves of the left side of the heart were much diseased; and this was the opinion given.

Symptoms increased more or less from day to day. Was once temporarily relieved by bleeding.

Dec. 26th.—Coughed up some half-coagulated blood, after suffering great oppression. Was bled again. Died the same night.

Sectio, Dec. 27th.—Body not emaciated. Subcutaneous veins marked all over the body by the brownish-red lines of sanguineous imbibition. About half a pint of serum in the right pleura, with some shreds of lymph. Many old adhesions on the left side. Lungs much congested, especially the right, in portions of which were some dark patches of pulmonary apoplexy. Pericardium throughout closely adherent to the heart, except a space of the size of a crown-piece on the posterior surface. Adhering membranes moderately thickened. Lining membranes of heart, valves, and arteries, deeply tinged with the claret red of imbibition. Aortic orifice contracted, admitting only a little finger; one of its valves rigid with bony deposit. They were all adherent to each other at the commencement of their margins, which at one conjunction formed separate fræna, between which and the membranous portions of the valves a probe could be passed. These valves would have admitted of some regurgitation. The left auriculo-ventricular orifice would only admit a finger. In its ring, and extending into the chief segment of the mitral valve, was a large irregular osseous deposit, which was broken on opening the orifice: the broken part was half an inch thick, and porous or cancellated, and the deposition of osseous matter an inch and a half in extent. The loose portion of the valve was thickened, but still flexible. Its tendinous cords thickened and corrugated, and their muscular pillars much enlarged. Tricuspid valve slightly thickened. Pulmonary valves healthy, except a *little oval perforation* near the attachment of the free margin of two of them. Left auricle much dilated, and lining membrane thickened, but the other cavities and walls were in ordinary proportions. Slight fibro-cartilaginous deposits at the arch of the aorta, but not causing roughness of surface.

In this case there was extensive disease, both obstractive and regurgitant, of the left valves of the heart, without the production of distinctive sounds;

and it illustrates well the position which I have elsewhere advanced, that in the production of valvular murmurs, as of sound in general, there must be motion of sufficient velocity, as well as a resistance or modifying influence opposed to it. The blood was not propelled through the contracted orifices with a force which could throw their resisting portions into vibrations sonorous enough to give the characteristic murmurs.

I have several more cases of this negative character, which it would be useless to relate.

OBSERVATIONS

ON

URINARY DEPOSITS.

By R. H. Brett, Esq. M.R.C.S.

[Continued from p. 851.]

Accidental Deposits from the Ingesta.

Having thus noticed, in a very imperfect manner, I fear, those deposits the constituents of which may be found in healthy urine, although not always in the same state of combination as we find them in that fluid, and having endeavoured to point out as completely as I was able the readiest modes of distinguishing them from each other, both as regards their physical character as well as their chemical habitudes, I now pass on to the consideration of the second class of deposits, viz. those which result from certain ingesta being taken up by the absorbents, and, after forming certain combinations, being transferred into the urinary canals. It is a well-known fact that many substances that have been received into the digestive apparatus, are removed again from the body with the urinary secretion, without undergoing any very marked change. A great many medicinal agents escape from the system by this outlet. The *oil of turpentine* and certain *balsams* communicate a well-known agreeable odour to the urine of individuals using these substances medicinally.

It has been affirmed by Cantu that *mercury* has been detected in the urine of persons using that substance in the form of ointment; he states that the urine in those cases yielded a deposit which, when dried and mixed with charcoal, gave by sublimation globules of metallic mercury. It has been satisfactorily proved by experiment that *nitre*, *prussiate of potass*, and *iodine* in the form of an hydriodate, have found their way into the urine of persons taking them in medicinal doses. The curious phenomenon of a blue, or bluish-green, deposit has been observed in the urine, and this substance has proved to be prussian blue. In all these cases, however, I believe the parties had been previously taking large doses of ferruginous preparations.

Garnier and Delens have several times observed urine of a blue colour; and this tint has appeared to depend upon a peculiar substance suspended through the fluid, which was not, however, prussian blue. It was but slightly soluble in water; neither alkalies nor acids altered its colour, excepting the nitric acid, which destroyed it. Braconnot has observed that this substance is entirely devoid of taste and smell, is of a deeper blue colour than prussian blue, and exists in particles of extreme fineness. When heated it yielded carbonate of ammonia and an empyreumatic oil, and was soluble to a slight extent both in water and alcohol at the boiling temperature. When the blue substance was treated with boiling alcohol, it imparted a green colour to that menstruum, which let fall upon cooling a powder of a deep blue colour, and almost crystalline structure. This blue substance taken up by alcohol was found to be soluble in acids, even the vegetable ones, such as the oxalic and gallic; its colour, however, becoming changed by such treatment from blue to red. The red acid solutions of this substance became again blue when the acids were saturated by an alkali. The blue substance being precipitated, the urine from which this blue deposit had taken place deposited, upon the application of heat, a fresh quantity of colouring matter, but of so deep a colour as to appear almost black, but which in other respects exhibited the same properties as the preceding. Braconnot seems to regard these peculiar deposits in the light of salifiable bases.

A black colouring matter has also been observed in the urine. Dr. Marcet

has noticed the urine of a child which contained neither urea or uric acid, and the colour of which was sometimes as black as ink. When treated with an acid it did not at first undergo any apparent change, but after some time it began to deposit a number of black flocculi, and became clearer. This black precipitate was insoluble in water and alcohol; but the sulphuric and nitric acids dissolved it, acquiring a black tinge. Water poured into these acid solutions precipitated it afresh, without its having suffered any material change. It was dissolved also by the caustic and carbonated alkalies, being thrown down from such solutions by the acids. With the metallic oxides it formed insoluble compounds, of a brown colour. Dr. Prout regards it as a weak acid, to which he has given the name *Melanic* acid. This organic substance, however, bears no inconsiderable resemblance to a black matter obtained from the urine by the following process:—Evaporate urine to a syrupy mass; add sulphuric or muriatic acid to it. After some time wash with pure water, by which means most of the adhering salts are removed. The brownish black mass remaining is to be treated with alcohol. Part only is dissolved, a part remaining in the form of a black powder, having many properties in common with that substance first noticed by Marcet. According to Berzelius it contains 65 per cent. of carbon. It is not improbable that the peculiar colouring matter in the urine of the child, noticed by Dr. Marcet, resulted from some morbid change principally taking place in the organic matter which gives to urine its peculiar colour in the normal state. It must be here observed, that the two deposits just spoken of, viz. the blue and the black, are not to be considered as coming under that class of urinary sediments immediately before our notice; such, I mean, as result from the transference of certain substances from the digestive apparatus to the urinary channels; they however, appeared of too much interest to be passed over in silence.

According to Woehler, who instituted a series of experiments on man, as well as on dogs, certain of the vegetable acids, when taken in frequently-repeated doses, caused an abundant deposit to take place from the urine. He swallowed tartaric acid in repeated doses, and found that his urine deposited upon cooling a white crystalline powder of tartrate of lime. The urine was also rendered unusually acid; and upon the addition of muriate of lime in solution to it, a further precipitate of a white colour took place. He found also that the citric and malic acids produced the same effects. Gallic acid also communicated to the urine the property of blackening the per-salts of iron. The experiments of Woehler would also seem to shew, that although certain of the uncombined vegetable acids can pass into the urinary secretion, either free or associated with bases, without undergoing decomposition by the vital agency of the digestive apparatus, still that when the neutral salts formed by the combination of vegetable acids and alkaline bases are introduced into the stomach, they undergo decomposition, and pass into the urine in the state of carbonates. But the extraordinary power of the vital principle in decomposing original compounds, and either simply re-arranging, or adding to, their elementary principles, so as to give rise to fresh combinations, is not limited to organic substances: thus sulphuret of potassium, when administered internally, has been detected in the urinary secretion in the mixed form of sulphuret of potassium and sulphate of potass.

Oxalate of Lime.

I have not spoken of the oxalic acid, or the deposit of oxalate of lime, in the urine, in connexion with that class of sediments which result from ingesta being transferred from the organs of digestion into the urinary apparatus, because, although experiment and observation alike have shewn that such a transference is as applicable to the oxalic as to any other vegetable acid, there can be no doubt that large concretions of oxalate of lime, as well as sediments of the same salt, are not unfrequently met with in cases where it has been quite impossible to refer it to the effect of certain ingesta, either containing the acid in a free state or saline form. What the peculiar condition of the system may be, or what may be the state of the urinary apparatus to give rise to this peculiar secretion, we are altogether in ignorance of. The experiments of Woehler go to prove that oxalic acid taken into the stomach

passes into the urine combined with lime.

M. Magendie relates the case of an individual who passed an orange yellow coloured concretion, consisting of the oxalate of lime. That person had been in the habit of eating large quantities of sorrel daily, for nearly the space of a year. The oxalate of lime, indeed, in the form of a urinary sediment, is an exceedingly rare occurrence. Dr. Prout had only seen it once when he published his work on Calculous Disorders, but had noticed it in some instances apparently mixed with what he calls the lithic amorphous sediments. Magendie in his work says that he has never seen it in the form of sediment. In the case related by him, and which I noticed above, the concretion was six or seven lines in length, and two lines in diameter.

I have myself detected this salt more than once in those non-crystalline deposits, consisting principally of the lithates; but even in such deposits I believe it has not unfrequently been confounded with urate or lithate of lime, which last is almost constantly found in small quantities mixed with the urates of ammonia and soda. This source of fallacy may be effectually avoided by taking care to remove previously all the matter contained in the deposit which is soluble in boiling water. If there shall then remain an insoluble substance, yielding by ignition a white ash, dissolving with effervescence in muriatic acid, and giving other evidences of the presence of carbonate of lime, there can be little doubt that oxalate of lime was mixed with the urinary deposit. If, on the other hand, all the urate of lime had not been carefully separated before ignition, the latter by its decomposition would yield carbonate of lime, which, if taken under such circumstances as evidence of the previous existence of oxalate of lime, would be evidently erroneous.

I have lately had an opportunity of examining a specimen of urine letting fall the oxalate of lime in the form of a non-crystalline sediment. The urine was given to me by Mr. Bird; and as it offers some points of considerable interest, both from the nature of the deposit as from other conditions of the urine itself, I shall briefly relate the case, and the result of experiments on the urine.

The individual, a man of about 35 years of age, has for the last twelve years been employed in a sedentary occupation; was formerly in the army, in a foreign service, when he was in the habit of eating large quantities of sour crout. Never had to his knowledge partaken of preparations of sorrel. Rather more than twelve years ago he attempted to raise, in a constrained position, 1 cwt. in each hand. In this, however, he failed, but felt something give way in his loins, followed by hæmaturia. This continued for some months, and then went off without medical aid; since which, upon any particular exertion, especially during the summer, he has had a discharge of bloody mucus in his urine, mixed with an amorphous deposit. During the winter he is generally free from these symptoms. They returned, however, in November, 1835, with increased severity, attended with extreme lumbar pain; no pain in the course of the ureters, no numbness of the thighs, or retraction of testicles. It was at this time that the urine was examined: it was of a dark reddish-brown colour, opaque from the suspension of the insoluble matter through it; its specific gravity was 1·060, exceedingly high; it exerted an acid re-action, which it did not lose for some days. After remaining twenty-four hours at rest, a deposit ensued, of a greyish-brown colour, the supernatant liquor still remaining turbid, though in a less degree than at first. When thrown upon a filter, a perfectly transparent fluid, of a rich claret colour, came through; the residue on the filter was washed with distilled water, until the wash fluid was no longer coloured; the insoluble residue on the filter was found of a greyish-brown colour, evidently tinged with the colouring matter of blood, which could not be entirely separated by washing. When a portion of it was treated with a little diluted nitric acid, and heat applied, a solution was obtained without effervescence, yielding, by evaporation, a saline pellicle, of a pale yellow colour, but giving not even the slightest trace of the presence of lithic acid or a lithate: when a portion was incinerated, it blackened, and rapidly passed into a bulky white ash (the rapidity with which the carbonaceous matter is dissipated, both in calculi as well as in urinary deposits consisting of oxalate of

lime, is highly characteristic); this white ash was abundantly soluble in muriatic acid, with evolution of carbonic acid gas. The acid solution was boiled, and treated with an excess of caustic ammonia; no precipitate ensued, pointing out the absence of the phosphates. The further addition of oxalate of ammonia caused a copious precipitate to take place. The claret-coloured fluid which had been separated from the deposit by filtration was then boiled; it became opaque from albuminous impregnation, and a number of light flesh-coloured flocculi came down; these, when collected on a filter, possessed a brick-red colour, were very difficult of incineration, and yielded a fixed residue, of a pale-brown colour, consisting mainly of oxide of iron. The urine, when filtered after ebullition, differed in no respect from the healthy secretion in colour.

Deposit of Red Particles of the Blood.

It is a well-known fact, that in various diseases connected with a deranged condition of the kidney, the red part of the blood, mingled with a smaller proportion of serum, finds its way into the urinary bladder, where it becomes mixed with the natural urinary secretion, giving very different appearances to the latter fluid under different circumstances of admixture, and according to the length of time it has been mixed with it. Thus it sometimes happens that in consequence of the small quantity of the colouring matter of the blood present, it shall remain for a considerable time either in a state of solution or mere suspension in the urine, without, however, interfering with its transparency, at the same time communicating to it a greenish tinge, so precisely like that produced by the colouring matter of bile, that it would be impossible to distinguish the one from the other by mere inspection; at other times, the quantity of red colouring matter being more abundant after the urine has stood some time, a copious precipitate, of a bright vermillion colour and granular appearance, possessing also considerable specific gravity, manifests itself: the brightness of the colour is sometimes exceedingly striking, quite equal to that of arterial blood, and doubtless resulting from the action of the salts of the urine upon the colouring matter of the blood; for it has been clearly shewn by Dr. Stevens, that certain saline substances have the power of converting the black colour of venous into the bright red of arterial blood. When, however, the deposit is examined some considerable time after the urine has been voided, it will frequently be found to have assumed a dingy brown colour; and it is in these cases that the supernatant fluid usually possesses a greenish colour, from small portions of red colouring matter (the latter having undergone some change) being still suspended through it. It sometimes happens that urine containing blood assumes quite a gelatinous appearance after it has been voided, moulding itself to the form of the containing vessel, looking not unlike thin calves'-foot jelly, tinged with red colouring matter, the latter occupying generally the lower stratum of the mass. When urine of this description is briskly agitated, the gelatinous appearance is entirely destroyed, and when thrown upon a filter, it passes through without much difficulty, leaving behind a small quantity of mucus, tinged with red particles. In some cases urine of this description contains mere traces of urea and uric acid, but in all cases is highly albuminous; it is occasionally, though not necessarily, alkaline in its reaction. This state of things was well marked in the case of a girl, a patient in Guy's Hospital, who died of fungoid disease of the kidney.

How to distinguish this Deposit.

Having thus noticed the more striking physical characters of that form of deposit which consists of the red particles of the blood, it is necessary that those chemical means should be pointed out which are alone capable of distinguishing it from all other urinary sediments, more especially since certain colouring matters, even of a vegetable nature, are capable of being transferred into the urinary secretion, and communicating to it and its ordinary deposits a colour in many respects little differing from that possessed by the colouring principle of the blood; for example, hematine, the colouring matter of the hæmotoxylon campechianum—olizarine, that of the rubia tinctorum—and the colouring matter of rhubarb—are all capable of passing undecomposed into

the urine; the two first also have a strong affinity for calcareous salts, especially phosphate of lime; they are also capable of tinging the alkaline and earthy lithates: therefore, without a due knowledge of this fact, and of the proper means of determining the difference, such tinged urine and sediments might be put down to the effect of the colouring matter of the blood.

In the first place, then, it may be stated as an invariable rule, that urine containing red particles of blood, either in the form of a deposit, or merely suspended through it, becomes affected by the application of heat, either manifesting a turbidity, or undergoing coagulation,—for red particles are never passed without an accompanying portion of serum, by which the urine acquires an albuminous impregnation; besides which the red particles of the blood, when freed as much as possible from serum, are themselves coagulated by heat, in consequence, I believe, of the constant association of the red colouring matter with fibrine or albumen, so modified as to be capable of undergoing solution in water; and it is not improbable that it is only when the red parts of blood are combined with a certain quantity of fibrinous matter or modified albumen, that they are capable of undergoing solution in water,—for where red particles form a sediment in urine, they are found insoluble in water, although they are still combined with a certain quantity of fibrinous or modified albuminous matter. If this deposit be collected on a filter, washed and dried, it will pass into a dingy red or brown colour, although when suspended through, or deposited in urine, it possesses a bright red hue. If it be ignited, it inflames, evolving a strong odour of burnt horn, and ultimately leaves an inconsiderable pale red ferruginous ash. This circumstance alone would serve to distinguish it from any other deposit which might assume a similar colour. When thrown down from the urine, from any of the urinary salts which may become precipitated, tinged with vegetable colouring matter, such as hematine or olizarine, it will yield a white ash by ignition, or leave no fixed residue at all. Again, the vegetable colouring matter will be changed from red to blue, or bluish violet, by the action of an alkali, and the acids will rather heighten the red tint.

[To be continued.]

CASE IN WHICH DEATH ENSUED

IN CONSEQUENCE OF

NITRIC ACID POURED INTO THE EAR;

ALSO A CASE IN WHICH THE EPIGLOTTIS WAS DIVIDED, IN AN ATTEMPT AT SUICIDE.

By J. Morrisson, M.D., M.R.C.S.,

And Surgeon to the Newry Dispensary and Fever Hospital.

Catherine O'Neill, aged 40, of a naturally good constitution, but latterly addicted to occasional drunkenness, had a quantity of nitric acid poured into her right ear, on the 6th of June, 1833, while in a state of intoxication.

I saw her about a week afterwards, when she stated that she and her husband were in the frequent habit of quarrelling; that she was roused from her sleep on the day above mentioned, by a severe burning pain in the right ear, and that this continued, though in a much milder degree, for two or three days, but had then altogether subsided; also, that she has since been very weak, unable to stand without assistance, and confined to bed; but has had no thirst, pain of head, nor heat of skin. The daughter of this woman stated, that her father on coming in, and finding her mother in bed drunk, went out, and returned in a few minutes, when he poured a great part of the contents of a phial which he had in his pocket into her mother's ear, and that the sides of her face and neck were immediately changed to a yellow colour, which could not be washed off*. She also states, that in six days afterwards a thick, stringy, membranous slough, was detached from the auditory foramen; and that this was followed, on the subsequent day, by a very copious hæmorrhage, probably to the amount of twenty ounces; and that on the day after this, her mother totally lost the use of her right arm, and was in such a state of debility, as to make the family expect her immediate dissolution, and cause her father, expecting that he would be committed as his wife's murderer, to perpetrate the act on himself which will be afterwards mentioned.

* It was discovered that O'Neill, the husband, procured nitric acid when he went out at the time specified.

There were now, the eighth day after the receipt of the injury, several ulcerated spots over the surface of the ear, particularly in the concha; and the lobe seemed to have altogether lost its vitality. Part of the face and neck was also in a state of ulceration; there was a trifling ichorous discharge from the meatus externus, and the sense of hearing was abolished. There was no headache, nor was there any apparent febrile symptoms. Pulse 88, small, weak, and intermitting; the skin's temperature below the natural standard; there was no stupor, stertor, nor vertigo; the debility seemed alone to demand attention.

Notwithstanding the plugging of the ear, and the application of astringent lotions, together with the internal administration of tonics, animal broths, &c., the hæmorrhage returned to some extent, almost daily, for about a month, when it ceased, and the general debility during that time increased. A fortnight after the beginning of the illness, the right side of the body, the use of which, from the onset, seemed gradually declining, was so deprived of its usual power, and its different parts so affected with frequent tremulous motions, which even in bed were quite apparent, as to make it evident that one half of the body was labouring under paralysis agitans. This latter affection continued about five weeks, when a considerable amendment took place, both as respects it and the general state of the system. The muscles of the right side were now more under the dominion of the will, and the tremulous motions had very nearly subsided. The woman at this time determined on seeing her husband, who was in hospital here, and by the support of two persons she walked through several streets to him; but on her return home she felt greatly exhausted, sunk into a state of general prostration, and so continued till her demise, which took place about six weeks afterwards. The side which had been subjected to the paralytic affection, with the exception of the arm, which remained totally deprived of its use, was for several weeks before her death quite free from the tremulous motions, and as capable as the other of the voluntary. Articulation remained distinct, and the mental faculties were unimpaired; the powers of the system at large, more than of individual parts, seeming to have undergone such thorough decay. There was, however, some cough, with muco-purulent expectoration, and night perspirations.

Dr. Mollan and I examined the body after death. There was much emaciation; the lower part of the right ear was away; a cicatrix occupied the remaining portion, and the meatus externus was much wider than natural. The dura mater presented no unusual appearance except in one spot, about the diameter of a sixpence, opposite the foramen auditorium internum, which seemed of a somewhat darker colour than it should be, but it was not thickened nor adherent on either side. There was not effusion of serum, lymph, nor pus, but a clot of blood about the size of a pea was found lying exactly at the entrance of the meatus internus. No morbid appearance could be discovered in any part of the brain, save some semblance of ramollissement of that portion of it which corresponded to the petrous portion of the right temporal bone; and even this was very conjectural. The right petrous bone itself, however, was completely carious, and the seventh nerve of this side, when compared with that of the other, *seemed* to have undergone a degree of wasting. These were the only appearances worthy of remark which the examination of the head had elicited. The lungs presented nothing peculiar.

This case seems to me interesting in several points of view, but particularly the following:—First, in the very novel and singular mode which was resolved on to effect death. Second, in perfect paralysis of the arm, and in paralysis agitans of the side, occurring conjointly and at the same side with, and following such an injury as is mentioned; and these coming on after copious evacuations of blood, and subsiding (the paralysis agitans was totally done away with very soon after the hæmorrhage from the ear ceased) as the blood subsided*. And third, in such extensive caries of the petrous part of the temporal bone, without the sensation of pain, or of almost any symptom either before or after death, to denote inflammatory

* Would the detriment which the portio mollis of the seventh must have received from the action of the nitric acid, and the communication of the affection to the calamus scriptorius, or corpus restiforme, to both of which we know this nerve is connected, throw any light on the pathology of paralysis agitans?

action either of it, the brain, or its membranes.

Case II.—On the morning of the 14th of June, 1833, John O'Neill, a barber, aged 44, husband of the woman whose case formed the preceding subject. On the eighth day after having poured the nitric acid into his wife's ear, supposing she was dying, he made a dreadful gash with a razor into his own throat, between the os hyoides and thyroid cartilage*.

I saw him very shortly afterwards, and had him conveyed to the hospital. The wound extended very deep, and so far across the neck, as to lay bare both carotid arteries, though neither was injured. Speech was altogether suspended when the wound was open, but returned, though nearly inaudible, when closed; and air passed through the wound freely. The surface of his body was cold, his face pallid, pulse scarcely perceptible, and his shirt, waistcoat, &c. saturated with blood. The hæmorrhage had then ceased. He was greatly tormented by cough. The wound was sponged and cleansed, when these vessels commenced to bleed anew. These were secured, the edges of the wound approximated by means of four sutures and adhesive straps, and the patient placed in bed with his head well raised by pillows. When visited in the evening, he was labouring under a constant suffocative cough; his deglutition was most difficult, and part of his drink came through the wound. The tube of a stomach pump was attempted to be passed into the œsophagus in the morning, so as to give him his drink, &c. by this means, but without avail, as the most violent cough and sense of suffocation were induced whenever the extremity of the instrument came near the seat of the wound. An attempt was now made to pass an elastic tube, but with a similar result; so that any drink which he got down, and which I believe was very little, was taken in the ordinary way. On the next morning, the cough and difficulty in deglutition were fully as urgent as on the day preceding; and as these were most harassing, and the drink continuing to escape through the wound, I resolved on opening this anew, fearing I had included a portion of the mucous lining of the trachea in the ligatures, as I could in no other way account for such a continued cough. On removing the dressings and sutures, I found the mucous membrane had been perfectly free from both, and could not discover any thing either by touch or vision which would be likely to excite such seeming irritation. I again put in three sutures, kept the wound closed by raising the head so as that the chin would rest on the upper part of the chest, retained it in this position by bandages, and dressed it, with the view of diminishing the seeming irritability of the part, with small bits of lint which had been made a little moist with tincture of opium. In the evening the harassing cough still continued, but he then could swallow some liquid put into his mouth imbibed by a bit of sponge; but from the receipt of the injury to this time, he said he was quite certain no fluid had entered the œsophagus. The next day, both the cough and difficulty in deglutition had in some measure abated. The opium dressings were persevered in. From this period all the uneasy symptoms gradually subsided, the wound commenced to granulate, the cough became much less urgent, and deglutition was performed with tolerable ease. He was discharged from hospital about four weeks afterwards, the wound being then healed, and his health nearly restored; some cough, hoarseness, and a low croaking voice, merely remaining as untoward symptoms. About three months afterwards, this man was admitted into hospital, on account of an inflammatory affection of the bladder; this was accompanied by a low typhoid fever, and quickly succeeded by death.

On inspecting the appearance of the parts connected with the former injury of the throat, it was found at the *post mortem* examination, that the epiglottis was deficient in almost the entire of its left lateral half; that its edge at this side was thick and marked by an indentation of about a line in depth, and that the arytenoid cartilage of the same side was considerably enlarged, and as as it were forced over toward its fellow, as if to supply the place where the epiglottis was wanting.

This case which was seen by several of the medical gentlemen of this town, also appears to me interesting, not only in giving us the symptoms of an injury

* We give this paragraph as we find it in our Dublin cotemporary.—Ed. Gaz.

of the epiglottis, but in shewing that disease may act to a great extent, even on this important organ, without such serious consequences ensuing, as might, at first sight, be naturally imagined. From the constant cough, sense of suffocation, inability to swallow, and almost total loss of voice, which immediately supervened the wound of the throat, I think it may clearly be inferred that the epiglottis had been injured, and as its left lateral half was found wanting at the *post-mortem* examination, I presume it may also be inferred, that the injury consisted of an incision extending from the left side of its base, in a somewhat longitudinal direction, probably not so far as to cause amputation in the first instance, but so far as to incapacitate that side from maintaining its vitality, and of course causing it soon afterwards to slough off. Wounds of the epiglottis are very rare, and it is difficult to conceive how the present one was inflicted, unless we suppose the most determined efforts at self-destruction.*

SUGAR OBTAINED FROM THE BLOOD OF A PATIENT, IN DIABETES.

To the Editor of the Medical Gazette.

Sir,

Having lately succeeded in obtaining sugar from the blood of a diabetic patient, and finding that the possibility of doing so has been denied by Wollaston and Marcet, I have been induced to make the fact public through the medium of your journal.

The eminent chemists above-mentioned failed in detecting the ferrocyanate of potash in blood, when they knew it to be actually present, which should have made them more cautious in denying the presence of sugar. Besides, the experiments of Wollaston on serum, with and without an admixture of sugar, were not sufficiently decisive to be considered an *experimentum crucis*.

The subject of the following experiments is at St. George's Hospital, under the care of Dr. Wilson, at whose request I examined the blood and urine. The case is well marked, the urine having amounted to twenty-eight pints in the twenty-four hours.

Four ounces of urine, when slowly evaporated to dryness, and purified by alcohol, produced two drachms of whitish sugar, in the form of granular masses, into which it broke spontaneously.

As twenty-four pints of urine were passed on this day (October 26th), the whole quantity of sugar formed in the system would amount to a pound and a half in the twenty-four hours.

Some weeks after, when the daily quantity of urine had decreased to about sixteen pints, eight ounces of blood were drawn towards evening. It yielded about five ounces of opaque serum, of a milky appearance, which was treated in the following manner:—

On gently heating it, a quantity of albumen was deposited; the liquid assumed a dark colour, and on being poured off and evaporated to dryness, left an abundant semitransparent residue.

On digesting this mass in hot alcohol, a solution was obtained, of a very pale straw colour, which, by spontaneous evaporation, produced crystals of carbonate of soda and chloride of sodium.

A thick syrup was left, which, being carefully drained off upon a watch-glass, and evaporated to dryness, became a light brown transparent mass, which, being somewhat charred, smelt strongly of burnt sugar.

Its taste, though not purely saccharine, was nevertheless decidedly sweet, and could be exactly imitated by a mixture of salt and sugar. In its appearance, deliquescence, and general properties, it perfectly resembled a former specimen prepared from the urine, which was also charred.

The syrup produced by its deliquescence, on being mixed with sulphuric acid, was instantly blackened, and deposited small carbonaceous flakes.

The whole quantity obtained from 8 oz. of blood, was about 4 grains; it would therefore require 7½ pounds of blood to furnish a drachm. This being the case, I think the error of Wollaston and Marcet lay in their attempting, not to *obtain*, but to *detect* the sugar; a substance whose only characteristic property (its sweetness) is completely obscured by foreign admixture.

To conclude: the hypothesis of Rollo, that diabetes originates in the stomach,

---

* Dublin Medical Journal; March 1836.

is greatly confirmed by the circumstance that sugar exists in the blood; as the want of proof for this fact has been generally considered its weak point.

I am, sir,
Your obedient servant,
CHARLES MAITLAND.

St. George's Hospital,
Feb. 26, 1836.

DEATH BY THE GUILLOTINE.

To the Editor of the Medical Gazette.

SIR,

THE arguments of MM. Sue, de Fontenelle, and others, which you gave in your last number, satisfy me that death by the guillotine is not quite so instantaneous as many have supposed. But I cannot agree with M. Julia de Fontenelle that pain is for some time felt *both* in the head and in the body. I can no more believe the latter, than that when a man's leg is amputated, the man feels pain, and so does the leg. The fact seems to be, that the individual (so far as the head, *minus* the trunk, can constitute individuality) suffers pain—until hæmorrhage from the cerebral vessels takes place—which is not immediately, but, according to Mojon and others, after the lapse of seven, eight, or ten minutes.

I have been reminded, by your notice of the subject (which was induced, I presume, by the recent executions in Paris), of a case which I read in an American medical publication, the Boston Journal, about a year and a half ago. It was communicated by Dr. Spencer, of Ticonderoga; the following is an abstract which I took at the time:

"E. D., aged 50, a man of hale constitution and robust, in making an effort to scale a board fence, was suddenly precipitated backwards to the ground; striking first upon the superior and anterior portion of the head, which luxated the dentata anteriorly on the third cervical vertebra. He was at length discovered, and taken in (as the patient said) after he had lain nearly an hour, in a condition perfectly bereft of voluntary motion; but being present I did not even suspect that the power of sensation was also gone, until the patient (whose speech remained almost, or quite perfect, and who was uncommonly loquacious at that time) said, did he not know to the contrary, *he should think he had no body*. His flesh was then punctured, and sometimes deeply—even from the feet to the neck; but the patient gave no evidence of feeling, and when interrogated, answered that he felt nothing; 'and,' added he, 'I never was more perfectly free from pain in my life,' but he remarked that he could not live, and accordingly sent for his family, twelve miles distant, and arranged all his various concerns in a perfectly sane manner.

"The head was thrown back in such a position as to forbid his seeing his body. The pulse was much more sluggish than natural. Respiration and speech but slightly affected, but were gradually failing; but he could articulate distinctly until within a few minutes before his death. *All the senses of the head remained quite perfect to the last.* He died forty-eight hours after the fall.

"Repeated attempts were made to reduce the dislocation, but the transverse processes had become so interlocked that every effort proved abortive. There was, undoubtedly, in this case, a perfect compression of the spinal marrow, which prevented the *egress* of nervous influence from the brain, while the pneumo gastric nerve remained unembarrassed."

This case, I think, proves conclusively that no agony, no suffering, no sensation whatever, can exist in the *body* after its connexion with the brain is dissolved. With the *head*, however, it is quite another thing. The brain and cerebral nerves are evidently possessed of sensibility, and can execute their functions as long as the encephalic circulation is maintained.

Your obedient servant,
PHILANCHUS ANGLICUS.

Feb. 29, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue a abréger."—D'ALEMBERT.

Zeitschrift für die gesammte Medicin, mit besonderer Rücksicht auf Hospitalpraxis und ausländische Literatur. Herausgegeben von DIEFFENBACH, FRICKE, und OPPENHEIM. Band I, Heft 1, und Heft 2. Hamburg; 1836.

OUR readers may be glad to know what this new Hamburgh medical journal

contains. The parts for January and February are before us, and give a fair idea of what the work is likely to be. Though, as its title states, its object is medicine generally, yet it has a special view to hospital practice, and the novelties in foreign medical literature. It professes to take for its model the English and French journals.

In their preface the editors point out the superiority of the clinical information procured in large hospitals, over that obtained within the limited range of private practice: they say they have already secured several contributors belonging to hospital establishments; and they invite others to come forward speedily with their interesting cases.

They dwell with evident satisfaction on the happy locality of Hamburg, as peculiarly suited for giving the earliest information respecting the literary productions of France, England, Holland, Denmark, Russia, and even America; and accordingly, confident in their resources, instead of coming out once in two months, like the Magazine of Foreign Literature. which preceded them, they have resolved to appear monthly.

The departments into which the journal is divided, are—1. Original papers; 2. Abstracts, or analyses of new medical works, chiefly foreign, and of a practical kind; 3. Bibliography, or an account of such new works as do not well admit of analysis; 4. Articles from foreign journals, condensed; 5. Original notices of new facts in surgery, midwifery, materia medica, &c.; 6. Miscellaneous department for personal news, correspondence, the principal professional occurrences of the day, &c.; and 7. The well-arranged index of literature which is to accompany the volume for the year.

The opening paper is by one of the editors, Herr von Fricke, of the Hamburgh General Hospital; he gives an elaborate *Report* of the surgical practice in that institution during the first six months of last year. This is followed by another paper, by the same author, *On the treatment of Orchitis by Compression.* To both these articles we shall probably take another opportunity of reverting.

In the analytical department we find a very full account (yet unfinished) of *Bouillaud on Diseases of the Heart:* critical abstracts of *French, Perier, and Coudougnés, on the nature of Cholera; Caffe on Poisoning with Tincture of Colchicum;* an ample sketch of the late discussion in the French Academy of Medicine *on Lithotrity* and *Lithotomy;* and a notice of a work by M. Franc, of Lyons, *On suprapubic Extraction of Stone from the Bladder.*

Then come the condensed abstracts from foreign journals, arranged under the several heads—Medicine, Surgery, Pharmacy, and Statistics; after this, there are short critiques on nine or ten new books, all foreign; and, finally, the miscellanies give us the *news*—among which we observe the announcement of Dr. *Parish's* (Paris's) appointment to the chair of Materia Medica in King's College. By the way, this is the only misspelt name we have noticed in our contemporary: we hope he will avoid the mangling and mutilation of proper names so shamefully practised by the French.

The February number opens with a paper, by Herr von Oppenheim, *On Amputation at the Hip-joint.* Drs. Stintzing and Trier, the physician and surgeon of the Hospital at Altona, are the next contributors: they supply *a Report* of their establishment for the year 1834. To these original papers we shall also recur.

The analyses in the second number are—1. of *Brayer's Nine Years at Constantinople*; and, 2. of *Arntzenius' treatise on Suicide*, published at Utrecht.

Among the papers extracted from foreign periodicals, we are glad to see *Mr. Daniel Noble's Observations on the Nerves of Taste, as distinguished from common Sensation;* and *Dr. Sloan's Case of Twenty-three Days' Starvation in a Coal-mine:* both from this journal. There are also extracts from the MEDICAL GAZETTE in the department of pharmaceutics—*Mr. Pereira on the Comparative Efficacy of various Diuretics*, and *Dr. Greenhow on the use of Sea-water.*

Notices of ten recent publications follow; and the miscellanies (among which, however, we do not observe any thing that would be particularly new to our readers) close the rear.

This general description of our new Hamburgh contemporary may serve for the present: we shall, as we have said, on subsequent occasions pay him our more particular respects.

A Manual of Medical Jurisprudence and State Medicine, compiled from the latest legal and medical works of Beck, Paris, Christison, Foderé, Orfila, &c. By MICHAEL RYAN, M.D. &c. &c. Second Edition.

WE did not notice this book when it was first offered to the public, because we thought it would die the death it deserved, or make a second appearance, after some time, in a much altered shape. It has now come forth in what is called a *second edition*, with all its old imperfections *multiplied* on its head. A more trumpery and worthless "Manual" has not issued from the press for many a day. *Trumpery* we entitle it, because the author has begged, borrowed, and—"compiled," the materials of which it is made up from all quarters; it is indeed "a thing of shreds and patches"—patches, too, which are occasionally of no small size—and almost in every instance selected without a particle of taste or judgment. *Worthless* we call it, because there is not half a page of what might seem to be the author's own that can be relied on: his references are few and carefully vague, and the hand of the plagiary can everywhere be detected.

The book, we observe, is extensively advertised as "Ryan's and Beck's Medical Jurisprudence." Now this we take to be a little "too bad" and too barefaced; especially when the only relation between the parties, whose names are so unceremoniously packed together, is that of pillager and pillagee. Beck is certainly plundered unmercifully; but he must not complain, for he has many brethren in the same predicament — Paris and Fonblanque, Christison, Orfila, &c.—all laid under levy of black mail, with the gentle denomination of being *compiled*. Dr. Ryan's motto surely ought to be what Voltaire applied to a kindred soul—

> "Il compilait, compilait, compilait !"

for he is a compiler *par excellence*.

But we hold that there is one quality in a good compiler, of which Dr. Ryan has no notion;—we mean that of *honestly* appropriating to each party what belongs to each. *Suum cuique* is not a part of his system. The author of the "Manual" so mixes up his own muddy cement with the harder materials employed in his crazy superstructure, that ordinary observers cannot say whose is this, or whose is that, part of the performance. There may be cunning in this—but there is no wisdom. Were the authors who have been plundered only to reclaim their property, our *compiler* would soon resemble the plucked daw in the fable. As an instance at once of the unfairness, and the slap-dash mode of compiling adopted by Dr. Ryan, we may mention, that in the body of his book we find two entire pages copied *litteratim* from a recent number of this journal, being an abstract of an article from the *Annales d'Hygiène*, in our exact phrases and words, yet without the slightest acknowledgment. The same trick was played, a short time since, in publishing the same extract in "my" journal,—but we said nothing, as few could have seen it there. We merely ask, is this fair, "honest Michael?"

It may be thought that we are somewhat severe in this notice, especially as we have not pointed out the particular overt acts and delinquencies which we lay to the author's charge. To do this, however, would occupy more space than we can at present afford. But only let the author, or his publisher, *reclaim* against our judgment, and we promise to bring forward such a body of evidence in support of our opinions, as will at once set the matter at rest. If we cannot serve up a rich banquet of blunders,—half a dozen at least on an average for every page we open,—and show on the part of the *compiler* a sample of literary unfairness (to use the mildest term) seldom heretofore exhibited, we are content to forego all character as honest and trustworthy critics.

A word or two more with Dr. Ryan ere we part—and that on the subject of fresh *compilations*.

In our last number but one, we published a lecture on White Swellings, by M. Lisfranc; last week the same paper appeared in the Medical and Surgical Journal, without any acknowledgment. Now that it was filched from us, is proved by this—that the lecture was not delivered as we gave it, but appeared in disjointed parts, some of which we took and omitted others, but so arranged as to make a complete paper. Well, where we began, our contemporary begins—where we ended, he ends—what

we omitted, he omits—what we inserted, he inserts. But let it not be supposed that the theft was made openly, or the reference to our journal omitted accidentally: oh, no! the beginnings of the paragraphs and sentences are carefully altered throughout the first page—as far, in fact, as he thought there was any risk of their being compared—after which the copy is exact, word for word, and line for line. Poor drudge!—he ought either to have left the wretched cheat unattempted, or to have given it a better disguise.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

PRINCIPLES *versus* PRACTICE.

QUACKERY ADVOCATED IN PARLIAMENT.

We last week alluded to the circumstance of both the medical and clerical professions having their vile quack nuisances to contend with: and we had almost ventured to congratulate the members of the other learned faculty on being free from all such pestilent annoyance. The profession of the bar has, indeed, ever been famous for taking good care of itself—not only in securing the dignities and emoluments of office, but in banishing from all possible competition, those unqualified intruders, whose impudence, urged by penury and avarice, would prompt them to try their chance as Counsel. Persons of profligate character, and notorious for their misdeeds, having often exhibited before courts of justice in the quality of accused, and having escaped the vengeance of the law through their peculiar adroitness and effrontery combined,—such persons, we say, flushed with their good luck, have often beeen known to advocate the propriety of throwing the bar open, and to declaim against the injustice of *monopoly* in that learned quarter. We give both the bar and bench the highest credit for hitherto resisting so successfully the inroads of those self-interested pretenders.

These remarks have been suggested to us by some late antics of the representative of Finsbury. We allude to his manœuvres, the other night, to introduce the *open* system into the *legal* profession. He who affects to contemplate quackery in *medicine* with such hatred and horror, it appears is most anxious to encourage every charlatan who wishes to figure in the courts of law in the character of an advocate. What this inconsistency of principle betokens, or what prospect the *honourable* member may at present have in view, we venture not to say; but the facts are as we state them.

On Wednesday night last, when Mr. Ewart's Prisoners' Counsel Bill was in committee, Mr. Wakley endeavoured to introduce, as as amendment, a clause that prisoners should not be limited for their defence to Counsel learned in the law. "Why," he asked, "should there be any such limitation? Why might not the prisoner be aided by *whomsoever he thought proper*, whether a member of the legal profession or not? He possibly might receive for answer, that Counsel were best qualified; but to that he should rejoin, *let the public judge for themselves*."

If this be not a direct plea for quackery generally, we are satisfied to forfeit our right henceforth to draw the simplest inferences. But we can see more in it than a mere oversight committed by the *honourable* member. It will be recollected that he has had no small experience of the practice of the bar, having been so often engaged in his own defence. However, let us hear what the Attorney-General said in reply.

The Attorney-General said that in

every country at all approaching to civilization, the practice of the law was under some sort of discipline and control. Whether it should continue to be so in this country, or being so, whether that control should reside in the societies which at present exercised the privilege, or be transferred to other authorities, were questions apart from the measure under discussion. If the proposition of the *honourable* member for Finsbury were adopted, *any convict three weeks returned from Botany Bay might put on a wig and gown, and take his place at the bar*. * * What the *honourable* member for Finsbury proposed amounted to permitting *any* person to defend a prisoner, and thus *an accomplished London thief might be appointed counsel, and be brought down to take his station beside the gentlemen of the bar!*

It is scarcely necessary to add, that Wakley's proposition was scouted.

But while we can admire the warmth with which the learned Attorney-General spurned the idea of having himself and professional brethren degraded by the association of quack counsel, we cannot help wondering that he did not put it to the Finsburian representative whether he thought it proper to countenance quack practitioners in *medicine*?—for the principle is exactly the same. If pettifogging pretenders to the character of counsel are to be admitted to plead at the bar, because *prisoners* make choice of them, and "because the public have a right to judge for themselves,"—*à fortiori*, the Eadys, the Morisons, and the whole host of mountebanks and charlatans, must be accounted fit and proper practitioners of medicine; because *patients* choose to have them, and the public *have a right to judge for themselves!* The learned Attorney-General probably did not think it worth while to bandy arguments *ad hominem* with the Finsbury M.P.; but *we* conceive it our duty to warn the profession what sort of advocate they must expect to find in Mr. Wakley to support measures for the suppression of quackery. He has even given notice, it seems, of an intention to bring in a Bill with that especial object. What its fate may be in such hands it is difficult to hazard a conjecture; but we would recommend the *honourable* member to be prepared for one ground of opposition which the measure may possibly meet with—namely, that it comes before the House introduced by a party who has so openly advocated the rights of charlatans.

REMUNERATION OF MEDICAL WITNESSES.

The member for Finsbury has obtained leave, we find, to bring in a Bill for the remuneration of professional witnesses attending coroners' inquests. We did not foresee any difficulty in carrying the point thus far, for the principle was generally admitted last session in Mr. Cripps' Bill, and the amount of the fee for *post-mortem* examinations actually fixed. Nor, indeed, do we despair of the measure being *ultimately* carried,—although, excellent as its object is, its chance of success is rendered not a little precarious by the unlucky hands into which it has fallen.

ANOTHER TRIUMPH OF PHRENOLOGY.

FIESCHI'S HEAD.

It was our lot, a few weeks ago, to record a remarkable example of the infallibility of phrenology, as displayed by Dr. Elliotson's examination of one Rhugoburg Sing, "in every respect a highly respectable character,"—who was hanged in India "for killing one man and wounding two others."

The examination of the head of Fieschi, which has recently taken place in Paris, is no less felicitous. Dr. Lelut, a gentleman of acknowledged experience and skill in such investigations, has found the organs of *vanity*, *firmness*, *courage*, and *destructiveness*, "extremely small, or altogether wanting!" The case is perfect, and would be weakened by comment.

BOMBASTES FURIOSO.

"SINCE our last, *three* out of *five* London Medical Journals have opened their fire upon *us and our institutions*, we conclude in anticipation of a critical session of parliament. The coincidence is not accidental; we are fully aware of the designs of our enemies, and prepared to meet them; we are *girded for the fight*, and that fight shall not be with shadows, but *hilt to hilt, in the face of our fellow-citizens!*"—DUBLIN JOURNAL.

Bless the silly, pugnacious, little man, what is he raving about? What *five* journals are those, three of which have opened a fire upon him? We did not think there were so many in London. But if he dreams that *this* journal is one of the three, we beg him to awake, and know that here has been no fire opened upon him and his institutions. *We* never thought "us" worth powder. Hoity-toity, what a doughty champion we have to deal with!—"girded for the fight"—"hilt to hilt"—and doing battle "in the face of our fellow-citizens!" What a formidable opponent we have got! we fancy we see a new Bombastes throwing down the gauntlet to us, or rather hanging up his boots, strutting about in his slippers, (ought he not to have a strait waistcoat?), and bidding us defiance—

> "Whoever dares these boots displace,
> Must meet *Bombastes* face to face!"

SCHOOL OF PHYSIC IN IRELAND.

LETTER FROM DR. LENDRICK.

To the Editor of the Medical Gazette.

SIR,

I BEG leave to state the facts connected with the recent proceedings in the School of Physic in Ireland, to which you allude in your Gazette of Saturday last (20th Feb.)

I was elected Professor of the Practice of Medicine during the Christmas recess in 1832, and found that my predecessor (a *locum tenens*) had been engaged in a dispute with the Professor of Anatomy and Surgery, the latter having at the beginning of that session commenced to lecture on surgery at 3 o'clock, an hour that had appertained to the Professor of the Practice of Medicine during the eighteen preceding years.

From the advanced period of the session nothing could be done on my part; however, on the remonstrance of several students as to the inconvenience sustained by them from the delivery of two medical lectures at the same hour, I applied to the Provost and Senior Fellows before the ensuing winter. I suppose it is unnecessary for me to specify in full the inconvenience to which I allude, as the letter which bears Dr. Macartney's name (Gazette, p. 820,) states the objection of "interfering with tutors' lectures and those on divinity." The interference of two *medical* lectures with each other, would of course be still more objectionable, and such a practice is, in this city at least, unprecedented in any school.

On the 9th of November, 1833, I received a letter from the Registrar of T. C. D.*, informing me that the Board would not require as a qualification for a degree, attendance on any medical lectures delivered at 3 o'clock, except those on the practice of medicine. The Provost also mentioned, that *all* the facts of the case had not been stated, nor the consequences of the interference of hours, when the Board had permitted the surgical lectures at 3 o'clock the preceding session.

The letter of the Registrar was immediately forwarded by me to the Professor of Anatomy and Surgery.

A letter was sent from the Board to Dr. Barker (Registrar to the Professors) on the 30th of October, 1834, informing him that they would not recognise any medical lectures at 3 o'clock except those on the practice of medicine, and which he communicated to the parties concerned: I believe they also stated that whatever lectures were delivered by one Professor, they would consider but as one course. Just before the Christmas ensuing, the Registrar of T. C. D. wrote to the Professor of Anatomy and Surgery, prohibiting the delivery of his lectures at 3 o'clock, but on his remonstrance as to the advanced period of the session, and the inconvenience attendant on an alteration, the Board assented to his delivering the remainder of the course, with an intimation however, that they would not permit in future the delivery of a part of his statutable course at 3 o'clock.

Here then are *four* distinct resolutions of the Provost and Senior fellows between the date of the Provost's letter that you quote, Sept. 29, 1832, and your next quotation, Oct. 13, 1835. Why have you (who appear to have had access to the correspondence†) not only omitted to make the

---

* Trinity College, Dublin.

† Dr. Lendrick is here in error: we have seen no letter from the Provost or Board dated in the intervening period.—ED. GAZ.

slightest allusion to them, but even called on your readers to "mark the change that took place on the opening of a fourth session?"

Since the Provost and Senior Fellows have by law the power to make "rules and orders" to regulate the conduct of the University medical professors, who receive a large emolument (I believe several hundred pounds annually, each) from the *University funds*, independently of the pupils' fees, and since the practice to which the Board objected, continued, notwithstanding the order made by them *before* the commencement of the present session (see Gazette, p. 820,)—what alternative was left but to close their Anatomical and Surgical theatre at 3 o'clock? They must else either have permitted two medical lectures to be delivered at the same hour, or required the Professor of the Practice of Medicine to surrender the one hour possessed by himself and predecessors (now) for twenty-one years, in order that another Professor might select a second, to which he had only laid claim three years since, and against which claim five distinct resolutions, progressively more peremptory, had been enacted and promulgated in vain.

You assume that the Board have prevented the Professor from lecturing *twice* in the day; this is not the case; it is in the Professor's power to select for *additional* lectures on anatomy or surgery either the hour from 9 till 10, or, that from 12 till 1. Besides, he can lecture at any hour before 9 or after 5 P.M.; and I suppose it is unnecessary to add, that the medical lectures at Edinburgh commence at 8 in the morning, or that Sir Astley Cooper delivered for many years the best *surgical* lectures probably in Europe, at 7 in the evening.

Should the Professor decline to deliver surgical lectures at any other hour than 3 o'clock, it is not for me to calculate the consequences to our School of Physic; I can only say that no possible modification of the regulations would enable the student to *complete*, as you suggest, his education for the Edinburgh degree here, or indeed any where else, except at Edinburgh itself; inasmuch as the regulations of that University require that, at least, *two courses* should be attended at Edinburgh.

If, notwithstanding the well-meant "*warning*" of your correspondent, the foreign students should resort to our School of Physic as heretofore, with the object of graduating in Edinburgh, it will be in their power to make surgery one of the two courses they are *indispensably* required to attend there; and they will therefore suffer no inconvenience from the want of it as a separate course in our school, should even the deficiency continue. However, separately or not, the Professor *must** teach surgery to the students, and, I conceive, that the completeness of a school depends on what is taught, and not on its nominal division into departments under the same Professor.—Excuse this hasty letter.

Your obedient servant,
CHARLES LENDRICK.

PLAN FOR SECURING ADEQUATE

MEDICAL ATTENDANCE ON THE COUNTRY POOR.

PAROCHIAL DISPENSARY SYSTEM.

To the Editor of the Medical Gazette.

SIR,

I HAVE read with much satisfaction the several articles in your Gazette on the subject of medical attendance on paupers under the New Poor-law system, the evils of which are ably exposed both in your editorial remarks and by your correspondents, and with singular perspicuity and force by your correspondent "Ruricola." Nevertheless, I must confess I was disappointed by his last communication in your number for January 16, in which he explains his plan for amending the system; and notwithstanding the unqualified approbation you express of his scheme, I am induced to send for insertion, in your next number, one which I think still better adapted for all the purposes so ably advocated by you and him, as well as your other correspondents.

My plan is neither more nor less than the establishment of a Parochial Dispensary in every district, to which one, two, or three surgeons, might be appointed, according to circumstances.

The first object that should be kept in view by all parties, is to furnish, in the easiest and readiest way possible, proper medical and surgical assistance to such of the poor in every district, as cannot afford to purchase it for themselves.

The second object ought to be, so to arrange and distribute the medical charge of the poor amongst the practitioners of each district, as to do away with undue monopoly, and the undertaking on the part of any single individual, duties (and duties of such importance, too) which it is mo-

* I mention this, as you say "that surgery is no longer deemed requisite to be taught in the University of Dublin."

rally, not to say physically, impossible he can ever perform; and also to set aside that disreputable and degrading competition, by which one practitioner is induced to underbid another.

These two objects are not only compatible with each other, but they so far coincide, that the means which best promotes the one, will be found most effectually to secure the other; and the attainment of both will be attended with advantages to the public at large far more important than could arise from any paltry pecuniary saving.

To illustrate my plan, let us take a market town which is the centre of a union of parishes, the whole including a population of say from 10,000 to 20,000 inhabitants: let us suppose from two to six or eight medical practitioners reside in the town. A small house, containing at least three rooms, should be taken for a Dispensary, or two or three contiguous apartments in the Workhouse may be appropriated to that purpose. One of these rooms must be furnished with drugs, and the necesary means of compounding them, the fittings-up of which may cost ten or fifteen pounds. The necessary drugs, &c. will probably cost from fifteen to thirty pounds per annum. An apothecary or dispenser will be required; and either a junior practitioner who had not fully established himself, and whose time is consequently not entirely filled up, or the son or assistant of one of the medical men, or even a dispensing chemist, might in every such town be found to undertake the necessary duties, and probably for a salary of from fifteen to thirty pounds per annum.

In such a district as we are speaking of, two or three surgeons would be required, who should be chosen from the surgeons of the town, if possible by the rate-payers generally; but whether by them or the Guardians, some such rules as the following ought to be attended to in the selection:—

1stly. No surgeon should be appointed who had not resided at least two years in the district.

2dly. The preference should always be given to men of some experience, but who are not so old as to be infirm, and thus likely to make the office a sinecure.

3dly. The preference should likewise be given to members of the College of Surgeons; such a preference is due to them on all occasions from the public, as they have taken the only means in their power to prove to the world that they have been regularly educated, and are qualified to fulfil the duties of their station: others may be qualified, but the presumption is not in their favour, and it is, to say the least of it, highly discreditable to any man in the present day, to have entered upon the practice of his profession without a surgeon's diploma.

4thly. The surgeons should be chosen annually, and if, where there are several eligible candidates, a rotation could be established, it would be desirable.

5thly. The surgeons for the time being should be *ex officio* members of the Board of Guardians; they would be very useful members on many occasions, and always ready to be appealed to in cases of alleged sickness or infirmity, but of course would be excluded from the right of voting on all questions relating to themselves.

6thly. The salaries of the surgeons should vary according to circumstances. Let us suppose, in the present case, that the district or union includes a circuit of about five miles from the central town, and that it is in a medium state as to pauperism. I suppose a salary of from 50*l.* to 100*l.* per annum (take the medium, 75*l.*) to each of the two or three surgeons, would afford a very moderate remuneration for their services. It would, however, be much more respectable and consonant to the feelings, than any compensation calculated at so many shillings per head, as proposed by Ruricola and some others.

Thus we have seen that the whole expense of providing attendance and medicines for such a district, consisting, perhaps, of ten or fifteen parishes, would not exceed between 200*l.* and 300*l.* per annum,—a smaller sum, probably, than had been paid under the old system for far less efficient services. Of course, the principle being understood, it would be easy to vary the plan according to the peculiar circumstances of different districts. Let us glance at one or two such cases.

It may happen that a union may consist of two or three towns, each having resident surgeons, with or without a number of villages. In these cases a Dispensary, with one or more surgeons attached to it, should be established in each of the towns, and the country places united to those towns to which they are most contiguous.

Again, it may happen that villages included in a union may be so distant from the town or towns of such union, as to render applications for medical aid to the Dispensaries established there very inconvenient to the poor, and perhaps they may have been heretofore in the habit of employing medical men in other towns or villages nearer to them, but not now included in their union. In all such cases the districts in question should continue to be attended by the same practitioners, and from the same stations as before; for

it would not only be positive injustice to the established practitioners to force new men into their districts under the pretence of serving the poor, but most inexcusable cruelty to the poor themselves, to oblige them to seek for medical assistance at a distance of seven or eight miles, perhaps, from their homes, when they might obtain it, and had been accustomed to obtain it, within two or three. And it may be observed here, that whatever advantages in other respects may be expected from more extended unions, the dispensary districts ought never, if possible, to extend beyond a circuit of five, or at most six miles, from the central town or station; and in the larger unions these stations should be multiplied according to their extent.

Then as to the rules for regulating the Dispensaries, they would be very simple, and such as would naturally occur to all medical men; in short, they would be pretty much the same as those which regulate charitable Dispensaries in cities: each surgeon would have his days, and would be bound to attend all applicants on those days; he would also have his hours of attendance at the Dispensary, where all patients who were able would be expected to appear. Having once taken charge of a patient, he should attend him throughout his illness, as often as would be necessary. Then rules might be laid down for consultations, operations, &c. according to the convenience of the surgeons.

Extra fees should be allowed for midwifery, and perhaps vaccination. The surgeons should keep brief journals of the cases, and enter their prescriptions in the same book. Minor regulations would readily be suggested as they were called for. One word as to the admission of patients into the Dispensary:—In all cases, the certificate of a guardian, or parish officer, stating that the applicant belonged to the district and was receiving parish relief, or was an inmate of the Workhouse, would be a sufficient title to relief; in other cases, the certificate (of which there should be printed forms) of any guardian, or respectable rate-payer, stating that the applicant resided in the district, and had no visible means of paying for medical advice, should be admitted.

It will be observed, that one of the principal and most essential features of this plan is the establishment of a common Dispensary for the distribution of medicines; and as this is a great innovation upon the former practice, it will probably be the first to be objected to, as entailing an additional and unnecessary expense. There are several weighty reasons why surgeons who attend the poor should not be called on to supply them with the necessary medicines, but they are not all such as could be fully appreciated by the public. One, however, I will venture to state, because it is of itself quite sufficient to justify the innovation, and will be readily understood by every one. It is this:—The greatest advantage that the public (and the poor especially) would derive from the plan now suggested, would arise from the active competition amongst the surgeons of the Dispensary: he who attended most diligently, and proved himself most skilful in the treatment of his patients, would be most sought after by the poor; but mark the unfairness that would arise if his diligence and extra exertions entailed upon him likewise an additional expense for medicines. Add to this, that the Dispensary system will bring the medical treatment of the poor more completely under the eye of the public, and I think its advantages will be sufficiently apparent.

I fear I have trespassed too much on your space and on the patience of your readers; nevertheless, the subject is one of primary importance at the present moment, and if you think the plan I have propounded applicable to the exigencies of the occasion, you will join with me in requesting that other journals and respectable newspapers would take the trouble to reprint it, that it may be circulated widely amongst the public.—I remain, sir,

Your constant reader, and

A Country Practitioner.

March 2, 1836.

ROYAL INSTITUTION.

Friday, Feb. 19, 1836.

Professor Faraday on Magnetism as a common character of all the Metals.

The lecture of this evening was highly interesting, as it contained the first announcement of a *new fact*, or what is likely to be, ere long, generally admitted as such, though at present it rests wholly on analogical evidence. In proceeding to give his proofs that magnetism belongs to every known metal, the accomplished lecturer called attention to the other general properties of metals—their gravitation, their fusibility, combustibility, &c. — all of which are possessed by metallic substances in extremely different degrees. That magnetic power should belong only to two metals, iron and nickel, Dr. Faraday argued, was contrary to the usual disposition of nature, especially as it is under-

stood that either iron or nickel, raised to a certain temperature, becomes as destitute of magnetic virtue as any of the other metals. It was the observation of this last circumstance which seems to have led the Professor to infer, that most probably, if not quite certainly, if we could lower the temperature of the other metals—copper, tin, lead, &c.—to a sufficient degree, we should find them endowed with magnetism. All this was beautifully illustrated by experiment. But as we happen to have before us a paper just published by Dr. Faraday himself on this subject, in the *Philosophical Magazine* (for March), we shall probably make our readers best acquainted with his views by quoting his own words:—

"General views have long since led me to an opinion, which is probably also entertained by others, though I do not remember to have met with it, that *all* the metals are magnetic in the same manner as iron, though not at common temperatures, or under ordinary circumstances. I do not refer to a feeble magnetism, uncertain in its existence and source, but to a distinct and decided power, such as that possessed by iron and nickel; and my impression has been that there was a certain temperature for each body (well known in the case of iron), beneath which it was magnetic, but above which it lost all power; and that, further, there was some relation between this *point* of temperature, and the *intensity* of magnetic force which the body when reduced beneath it could acquire. In this view iron and nickel were not considered as exceptions from the metals generally with regard to magnetism, any more than mercury could be considered as an exception from this class of bodies as to liquefaction.

"I took occasion, during the very cold weather of December last, to make some experiments on this point. Pieces of various metals, in their pure state, were supported at the ends of fine platinum wires, and then cooled to a very low degree by the evaporation of sulphurous acid. They were then brought close to one end of one of the needles of a delicate astatic arrangement, and the magnetic state judged of by the absence or presence of attractive forces. The whole apparatus was in an atmosphere of about 25° Fahr.: the pieces of metal, when tried, were always far below the freezing-point of mercury, and as judged, generally at from 60° to 70° Fahr. below zero.

"The metals tried, were arsenic, antimony, bismuth, cadmium, cobalt, chromium, copper, gold, lead, mercury, palladium, platinum, silver, tin, zinc, and also plumbago; but in none of these cases could I obtain the least indication of magnetism.

"Cobalt and chromium are said to be both magnetic metals. I cannot find that either of them is so, in its pure state, at any temperature. When the property was present in specimens supposed to be pure, I have traced it to iron or nickel.

"The step which we can make downwards in temperature, is, however, so small, as compared to the changes we can produce in the opposite direction, that negative results of the kind here stated could scarcely be allowed to have much weight in deciding the question under examination, although, unfortunately, they cut off all but two metals from actual comparison. Still, as the only experimental course left open, I proceeded to compare, roughly, iron and nickel with respect to the points of temperature at which they ceased to be magnetic. In this respect iron is well known *. It loses all magnetic properties at an orange heat, and is then, to a magnet, just like a piece of copper, silver, or any other unmagnetical metal. It does not intercept the magnetic influence between a magnet and a piece of cold iron or a needle. If moved across magnetic curves, a magneto-electric current is produced within it exactly as in other cases. The point at which iron loses and gains its magnetic force appears to be very definite, for the power comes on suddenly and fully in small masses by a small diminution of temperature; and as suddenly disappears upon a small elevation, at that degree.

"With nickel I found, as I expected, that the point at which it lost its magnetic relations was very much lower than with iron, but equally defined and distinct. If heated and then cooled, it remained unmagnetic long after it had fallen below a heat visible in the dark: and, in fact, almond oil can bear and communicate that temperature which can render nickel indifferent to a magnet. By a few experiments with the thermometer it appeared that the demagnetizing temperature for nickel is about 630° or 640°. A slight change about this point would either give or take away the full magnetic power of the metal.

"Thus the experiments, as far as they go, justify the opinion advanced at the commencement of this paper, that all metals have similar magnetic relations, but that there is a certain temperature for each beneath which it is magnetic in the manner of iron or nickel, and above which it cannot exhibit this property. This magnetic capability, like volatility or fusibility,

* See Barlow on the Magnetic Condition of Hot Iron. Phil. Trans. 1822, p. 117, &c.

must depend upon some peculiar relation or condition of the particles of the body: and the striking difference between the necessary temperatures for iron and nickel appears to me to render it far more philosophical to allow that magnetic capability is a general property of all metals, a certain temperature being the essential condition for the development of this state, than to suppose that iron and nickel possess a physical property which is denied to all the other substances of the class."

THE LATE PROTESTS FROM THE METROPOLITAN SCHOOLS.

To the Editor of the Medical Gazette.

SIR,

I PERCEIVE with great pleasure, that the Students of the Metropolitan Schools have nobly come forward to disclaim any participation in the late disreputable transactions at the Crown and Anchor Tavern, and in just, yet temperate language, have expressed their disapprobation of the whole proceedings. Permit me, sir, as a Student of a Provincial School, to give my testimony in accordance with theirs; a testimony in which, I am sure, a majority of Provincial Students concurs, and which will tend to remove that odium which may have become attached to us, as a body, in consequence of the ill-directed efforts of some of our misguided brethren.

It would be superfluous on my part to make any observations on the proceedings of the meeting; the pages of your journal record sufficient to excite feelings of disgust in every unprejudiced mind; yet I cannot but remark, that the replies of the candidate, even as they are reported in the Lancet, if not decidedly erroneous, savour strongly of presumption. An air of self-confidence, and of contempt, is visible throughout, while that profundity of knowledge which alone could have warranted these, no where appears. If this be the case, need we be surprised that the examiner should have expressed (perhaps not in a very gentlemanly manner) his feelings at this improper bearing; and if the replies referred to above may be taken as evidences of the general professional knowledge of the candidate, it is not, I think, assuming too much to say, that his examination must have been far from creditable, and thus have afforded sufficient grounds for his rejection. In the eyes of the more industrious students, the Examiner is acquitted of injustice, and they are confirmed in their diligence and application,—new stimulus also is given to unassuming and unobtrusive merit.

I say the industrious class, not that I wish to imply that there was a want of industry on the part of the candidate, but, if I may be permitted the use of a technical expression, he was "ground"—for how long I know not. It is said that some require to be "ground" for more than two years; be that as it may, "grinding" has become a very lucrative profession, and the "grinders" a very important class of men; and if we may judge from some remarks made at the late meeting by one of the most eminent of the class, they alone are capable of determining as to the competency of a student to practise our profession.

Notwithstanding this, sir, I cannot divest myself of the opinion that this system is every way injurious to the interests of many students. Catechetical instruction cannot impart a knowledge at all comparable, either as to durability or usefulness, with that derived from close observation and study; yet there are many who rely upon it alone, and neglect every opportunity for solid and lasting improvement.

This is a matter of common observation, and its increasing prevalence has induced me to offer these remarks; and, in conclusion, I would observe, that if to a love for our profession are added industry and patient research, we may, without artificial aids, most certainly avoid

> Esse mala, exiguum censum, &c.

I am, sir,
Your obedient servant,
Σ.

Hull, March 3, 1836.

REPUBLICATION OF MR. LAWRENCE'S WORK ON MAN.

To the Editor of the Medical Gazette.

SIR,

I PERCEIVE you not only reject the letter I wrote in reply to Mr. Wickham, but you state I "ought to have more sense than to send a letter utterly unfit for your pages."

I had ever imagined that justice was even-handed, and that the editors of public journals professed its impartial distribution as the rule of their conduct. If such be the rule which you profess, I am at a loss to understand how you will reconcile the exclusion of my letter on account of its "coarse personalities," when you have admitted a no very measured attack upon my character and honesty as a publisher.

It is true Mr. Wickham did not mention

my name; but, sir, who can doubt (and I put it to your candour whether you for a moment doubted) the following sentence was directed to apply to me—" or with the *moral honesty* of the man who can *plunder* his fallen brother, and *rob* him of the only gains of their unhallowed craft."

I know nothing of Mr. Wickham any more than he does of me; but I humbly submit that as nice a sense of honour may be found in the breast of a p or bookseller as in the heart of a surgeon; and the good taste which precludes me defending myself from attack in the pages of your journal, should have saved me the necessity (by the suppression of what I conceive a very virulent, wanton, and uncalled-for, reprehension of my motives and intentions) of a reply.

However, sir, I leave the matter in your hands: your own character as a journalist is as much at stake as mine; and unless you admit my reply to Mr. W., I should hope you will be able to reconcile such a course upon much more tenable and adequate grounds than any you have yet advanced.

I call upon Mr. Wickham himself to explain why, in denouncing the principles inculcated in a certain publication, he has not thought proper to do so only after a period of three years since the last edition, and seventeen years subsequent to the first—why his zeal should have slumbered so long, only to burst forth at last in a tirade involving the unlucky publisher in his anathema.—I am, sir,

Your obedient servant,

EDWARD PORTWINE.

124, Aldersgate-Street,
Feb. 26, 1836.

[We can assure the reader that the above is a *very mild* letter compared with the former one sent us by Mr. Portwine. We ought, perhaps, to add, that the facts of the case stand thus:—Mr. Lawrence publishes a book containing certain passages, which are generally looked upon as calculated to do harm, particularly to young men: the author, either from conviction, or in deference to the opinion of others, suppresses the work at a considerable loss. Upon this another party avails himself of the literary labour of Mr. Lawrence, and issues a fresh edition. Mr. L. appeals to the Court of Chancery; and Lord Eldon rules that the work being *contra bonos mores*, is not entitled to the protection of the law. The publisher then sets at nought the author's wishes, disregards the alleged immoral tendency, and renders accessible to all a work of which he dare not have published a single copy, had not the law, in its wisdom, declared it to be too bad to be acknowledged as the property of any one.—ED. GAZ.]

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XXIV.

THE MINERAL ACIDS.

UNDER the head of *mineral non-metallic acids*, I shall examine *sulphuric, sulphurous, nitric, hydrochloric, nitro-hydrochloric,* and *carbonic* acids.

(a) Sulphuric Acid.

History, synonymes, &c.—This acid was known to Geber, the Arabian chemist, in the seventh century. In the state in which we usually meet with it in English commerce, it is termed *protohydrate of sulphuric acid, oil of vitriol, spirit of sulphur,* &c.

Native state.—It occurs in both kingdoms of nature. It is found in the waters of many volcanic regions. Thus the *Rio Vinagre* (the Vinegar River), which descends from the volcano of Gurose, in Colombia, to Popayan, has received its name from its acid properties, which it derives from being impregnated with sulphuric and hydrochloric acid.

Rivero states that a *litre* (equal to 1 $\frac{75}{100}$ imperial pints) of this water consists of—

	Troy grains.
Sulphuric acid	16·679
Hydrochloric acid	2·811
Alumina	3 706
Lime	2·471
Iron	traces.

Issuing from the crater of Mont Ida, in Java, is a river which also contains this

FIG. 91.—*Cascade of Vinagre.*

acid. In many of the grottoes of Italy it is likewise found. Dr. Thomas Thomson, in his "Mineralogy," states, that in Persia there is an earth so strongly impregnated with this acid, that it is used by the natives as an acidulous seasoner of food. Combined with bases (more particularly lime, alumina, barytes, and strontian), sulphuric acid is frequently met with.

Preparation.—The mode of manufacturing it varies in different places:—

1. *Nordhausen method.*—At Goslar, Nordhausen, and other parts of Saxony, the following process is adopted. Crystallized protosulphate of iron is calcined in the open air, and then distilled in earthen vessels. The product in the receiver is called *fuming sulphuric acid,* while *peroxide of iron* is left in the retort. Protosulphate of iron is thus composed:—

1 atom of Sulphuric Acid	=	40
1 atom of Protoxide of Iron ..	=	36
6 atoms of Water (6 × 9)	=	54
1 atom crystallized Protosulphate		130

By calcination, the greater portion of the water of crystallization is driven off, while the *protoxide* is converted, by the oxygen of the air, into *peroxide* of iron. By the subsequent distillation two atoms of sulphuric acid, combined with one of water, pass over.

2. *English and French methods.*—Although various methods of manufacturing sulphuric acid are adopted in England and France, yet they all agree in this, that by the combustion of sulphur, sulphurous acid gas is obtained, which is conveyed into a leaden chamber, where it becomes oxidized by an acid of nitrogen (nitric, nitrous, or hyponitrous acid), and converted into sulphuric acid.

(*a*) *The most improved plan* now followed in this country is the following:—Sulphur is burned on an iron plate, in a furnace, (Fig. 95, *a*,) the admission of air being regulated by one or more apertures in the iron door of the furnace. In the act of combustion every atom of sulphur unites with two atoms of oxygen of the air, and produces one atom of sulphurous acid gas; which is conveyed by a pipe or chimney (*f*) into a leaden chamber (*b*), the bottom of which is covered, to the extent of four or five inches, with water. The size of the chamber varies considerably in different manufactories. The one from which I made the accompanying sketch was 70 feet long, 20 feet wide, and 20 feet high.

To oxidize this sulphurous acid, and convert it into sulphuric acid, nitric acid vapour is generated (by the action of sulphuric acid on nitrate of potash, contained in an iron pot or basin placed on the furnace plate), and conveyed, along with the sulphurous acid, into the chamber. To facilitate the mutual action of the gases, steam is also conveyed into the chamber. Certain chemical changes now take place, one of the results of which is sulphuric acid, which dissolves in the water.

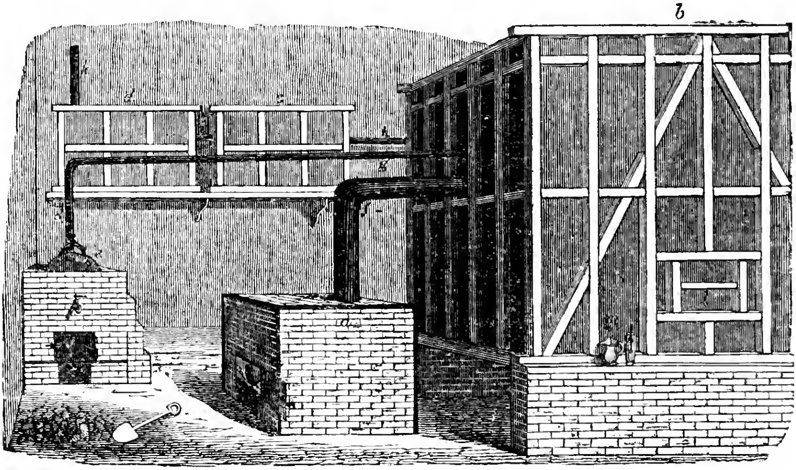

Fig. 95.

(*a*) *The furnace.*—In lieu of bars is an iron plate, on which the sulphur is burned. To heat this plate when the combustion is commenced, a few live coals are thrown on, and then a shovel-full of sulphur. The furnace-door has two apertures, one of which can be closed when the combustion is too rapid. On the plate is seen the *iron pot* containing the nitrate of potash and sulphuric acid. The sulphurous and nitric acids are conveyed by the chimney (*f*) into the *leaden chamber* (*b*). At the side of this chamber is seen the *man-hole* (*l*), by which the workmen can enter when the process is not going on. The strength of the liquid in the chamber is ascertained from time to time by a hydrometer: for this purpose a small portion of the liquid is withdrawn by the pipe (*m*). (*e*) The *boiler* supplying steam to the chamber by the pipe (*g*, *g*). (*c*) and (*d*) are *smaller leaden chambers*, through which the residual gas passes from the first, or large chamber, by the pipe (*h*) and (*i*), before it is allowed to escape into the air by the waste-pipe (*k*.)

Theory.—Let us now examine into the nature of the changes before alluded to. If dry sulphurous and nitrous acid gases be mixed, no change is observed; but if a few drops of water be admitted, a *crystalline compound* (*hydrate of hyponitro-sulphuric acid?*) is formed. When this comes in contact with a large quantity of water, effervescence takes place, binoxide of nitrogen is evolved, and sulphuric acid left

in solution. Davy thought this crystalline compound consisted of *sulphurous* and *nitrous acids*, and *water*; but Gaultier de Claubry states it is composed of

Anhydrous sulphuric acid....	68,000	or about	$4\frac{1}{2}$ atoms = 180
Hyponitrous acid	13,073		1 atom = 38
Water	18,927		6 atoms = 54
	100,000		272

Gay Lussac, on the other hand, regards it as a compound of *sulphuric* and *nitrous acids* and *water*, and his inferences are adopted by Dumas. Gaultier de Claubry's view is perhaps the most consistent, and therefore I shall adopt it, and accommodate our explanation accordingly.

Sulphurous acid abstracts oxygen from nitric acid, by which sulphuric acid is obtained, as well as some compound of oxygen and nitrogen (perhaps hyponitrous acid.)

Re-agents.	Results.
$2\ \ddot{S}$	$\dddot{N}$
$\overset{\cdot\cdot\cdot\cdot\cdot}{N}$	$2\ \ddot{S}$

It is probable, however, that the hyponitrous acid is not immediately formed, but that one atom of sulphurous acid abstracting an atom of oxygen from the nitric acid, the latter is converted into nitrous acid, which is further deoxidated by another atom of sulphurous acid; and thus is obtained the hyponitrous acid. It is not unlikely that binoxide of nitrogen may be also generated, as Dr. Thomas Thomson thinks.

By the union of hyponitrous and sulphuric acids with some water, the crystalline compound already spoken of is formed, and which, falling into the water of the chamber, is decomposed; the sulphuric acid is dissolved, and the hyponitrous acid converted into nitrous acid and binoxide of nitrogen. The latter gas escaping into the chamber, absorbs two atoms of oxygen, and is reconverted into nitrous acid, which, acting on more sulphurous acid, undergoes a similar series of changes to those already described.

On the large scale this crystalline compound is rarely formed, owing to the great excess of aqueous vapour in the chamber. It is, however, sometimes generated in the tube, or chimney, leading from the furnace to the leaden chamber.

Concentration.—When the liquid in the leaden chamber has acquired a specific gravity of 1·5, it is conveyed by leaden pipes into *rectangular leaden boilers*, where it is evaporated and concentrated; but in some manufactories this part of the process is omitted. The final concentration is effected by boiling it down in glass or *platinum retorts*; the latter, notwithstanding their great expense, are now usually adopted. The price, of course, depends on its size. Mr. Parkes had one which held 30 gallons, and cost about £360; but sometimes they are made so large that they are worth £1000. In this apparatus the acid is deprived of a part of its water and some sulphurous acid, and when it has attained a sufficient degree of concentration, it is drawn off by means of a platinum syphon into carboys.

By theory 16 parts of sulphur ought to yield 49 of protohydrate of sulphuric acid, namely—

16 of Sulphur.
24 of Oxygen.
9 of Water.
—
49 of Protohydrate of Sulphuric acid.

In practice, however, 48 parts may be regarded as the maximum; and few get so much as this.

(*b*) *Another method*, still followed in some manufactories, is the following:—Sulphur, mixed with one-eighth of its weight of nitrate of potash, (or of nitrate soda), is burned on iron or leaden plates, either placed within the chamber, or in a furnace on the outside.

Theory.—In this process one portion of the sulphur combines with the oxygen of the air, and forms *sulphurous acid gas*; while another portion decomposes the nitre, and furnishes *sulphate of potash*, and *binoxide of nitrogen*.

Re-agents.	Results.
2 Ox. (of the air.)	$\ddot{S}$
2 S	$\ddot{N}$
$\dot{K}\ \overset{\cdot\cdot\cdot\cdot\cdot}{N}$	$\dot{K}\ \dddot{S}$

The sulphate of potash is left on the plates; while the binoxide, escaping into the air, combines with two atoms of oxygen, and forms *nitrous acid*; which, reacting on some sulphurous acid, produces sulphuric and hyponitrous acids. The latter is decomposed by the water into nitrous acid and the binoxide, as mentioned in the previous process.

(*c*) Sometimes *bisulphuret of iron* is employed in lieu of sulphur to yield sulphurous acid.

(*d*) In France a mixture of treacle and nitric acid are boiled together, in order to produce the gases (binoxide of nitrogen and

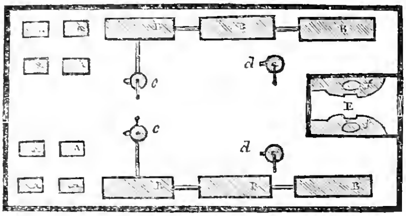

FIG. 96.—*Plan of a Sulphuric Acid Manufactory.*

A,—Rectangular leaden boilers.
B,—Leaden chambers.
E,—Retort house.

nitrous acids) necessary for the oxidation of the sulphurous acid. Oxalic acid is formed in the boiler (which is made of platinum.)

Preparation of anhydrous sulphuric acid.—Pure or anhydrous sulphuric acid may be readily obtained by distilling the *fuming* or *Nordhausen* acid in a glass retort, by a moderate heat, surrounding the receiver by ice. It condenses in a solid state in the neck of the retort, and in the receiver.

Properties.—(*a*) *Of the anhydrous or pure sulphuric acid.*—It is a crystalline solid, having very much the appearance of asbestos. It gives out dense white fumes in the air, like fluoride of boron. It melts at 64° F. and boils at from 101 to 122° F. It is composed of

1 atom Sulphur	16
3 atoms Oxygen (8×3)	24
1 atom Anhydrous Acid ..	40

(*b.*) *Properties of fuming, or Nordhausen sulphuric acid.*—This is a dark brown oily-like liquid, which gives out copious white fumes in the air. Its specific gravity is about 1.9. It is imported in stone bottles, having a stoneware screw for a stopper. Its composition is as follows:

2 Anhydrous Sulphuric Acid (40×2)	80
1 Water	9
1 Dihydrate of Sulphuric Acid	89

or,

1 Anhydrous Sulphuric Acid	40
1 Protohydrate of Sulphuric Acid..	49
	89

(*c.*) *Properties of protohydrate of sulphuric acid*, or the *strong sulphuric acid of English commerce.*—When pure, it is a colourless, transparent, inodorous liquid, of an oily consistence, having a specific gravity of 1,847 or 1,850. It boils at about 620° F. It has a most powerful affinity for water, and when mixed with this liquid evolves heat; condensation taking place. When exposed to the air, it abstracts water, and hence increases in weight.—It is composed of

1 atom Anhydrous Sulphuric Acid	40
1 atom Water	9
1 atom of the Protohydrate of Sulphuric Acid	49

Characteristic tests.—(*a*) If a solution of a barytic salt (say chloride of barium) be added to a liquid containing this acid in solution, a white precipitate of the sulphate of barytes is obtained, and which is distinguished from other insoluble barytic salts by two characters; namely, by its insolubility in strong nitric acid, or the alkalies; and secondly, by heating it with charcoal the sulphate is converted into the sulphuret of barium, which, by the action of muriatic acid, evolves sulphuretted hydrogen, easily recognised by its odour, and by its blackening paper moistened with a solution of sugar of lead. (*b*) Another test for sulphuric acid is a soluble salt of lead (as the acetate) which, occasions a heavy white precipitate of the sulphate. (*c*) Heated with organic matters, it gives out sulphurous acid gas, recognisable by its smell, and by its deoxidating properties. Thus, if we distil in a small tube retort, sulphuric acid with some gelatine, the liquid in the receiver will be found to contain sulphurous acid; and if to this a little iodic acid be added, sulphuric acid and free iodine are immediately formed: the latter may be recognised by its action on starch.

Impurities.—This acid is, I believe, never adulterated, though it is apt to contain impurities derived from its mode of manufacture. Thus it frequently holds in solution sulphate of lead, obtained from the leaden chamber. You may readily detect this by diluting the acid with water, by which the sulphate is precipitated.

Incompatibles.—It seems quite unnecessary to enumerate all the substances which are incompatible with this acid; because some, such as the alkalies, and their carbonates and many others, are known to every tyro. I would, however, particularly caution you against employing, simultaneously, sugar of lead and this acid. In more than one instance I have known a pill containing sugar of lead given in hæmoptysis, and at the same time draughts exhibited containing the infusion of roses—one of the ingredients of which, you are aware, is this acid. Now the efficacy of the lead is completely destroyed by the sulphuric acid, since an insoluble sulphate is formed.

Physiological effects.—In the *concentrated*

form, hydrous sulphuric acid is a powerfully corrosive poison. Its chemical action depends in a great measure on its affinity for water, so that when placed in contact with the animal tissues, it first destroys their vitality, and then exercises its attractive power for water—charring or carbonizing them, and giving rise to the formation of the sulphate of ammonia. Assuming the composition of the fibrous and albuminous tissues to be that which Raspail represents (though I would not have you infer I am an advocate for his notions in this respect),—the phenomena of the local action of this acid are readily comprehended:—the acid attracts the *water*, precipitates the *carbon*, and unites with the *ammonia*. On examining the stomachs of persons poisoned with this acid we sometimes find them whitened, but where the action has been more powerful they are usually blackened. Here is a wax model, executed by Mr. Miller, of No. 3, Theobald's Road, which shows admirably the destructive operation of this acid—the blackening of the part touched by the acid—the acute inflammation of the neighbouring parts. The unfortunate individual (a medical man) was assistant to my friend Mr. Saner, of Finsbury-square. In Dr. Roupell's plate the same kind of blackening is shown.

The *symptoms* of poisoning with this acid are as follows:—Alteration, or even destruction, of the soft parts about the mouth; burning pain in the throat, stomach, and bowels; frequently, alteration of the voice, from the swelling, &c. of the parts about the larynx; breath fœtid, from the decomposed tissues; constant and abundant vomiting of matters which may be bloody or otherwise, but which effervesce by falling on a marble hearth; bowels variously affected, sometimes constipated, though usually purged, the stools being bloody. The constitutional symptoms are principally those arising from a disordered action of the vascular system: thus the pulse is frequent and irregular, feeble, often imperceptible; extremities cold; great feebleness, or even fainting, with cold sweats. The same constitutional symptoms are observed when the stomach is wounded or ruptured. One remarkable characteristic is, that the mental faculties are unaffected, even up to a few minutes before death.

If the acid be *somewhat diluted* (as the dilute sulphuric acid of the Pharmacopœia) it ceases to be a corrosive, but is still a powerful irritant poison, causing acute gastro-enteritis.

When *largely diluted*—that is, in a state proper for therapeutic employment—its irritant operation is no longer perceptible, unless indeed the stomach be inflamed. In the latter case it excites pain, heat, and sometimes vomiting. If, however, this viscus be in a healthy or merely weakened condition, the acid acts as a *tonic*, that is, it increases the appetite, and assists the digestive function. In some cases of mild fever, and more frequently in hectic fever, it allays thirst, diminishes preternatural heat, checks profuse sweating, and even, I have in several instances seen, reduces the frequency of the pulse: these effects have given rise to its appellation of *refrigerant*. Sometimes it increases the secretion of urine,—at the same time rendering this fluid unusually acid.

The continued use of the acid, however, generates a slow kind of gastro-enteritis; heat and pain are experienced in the throat, stomach, and intestines; the digestive functions are disordered; gripings are frequently observed; sometimes purging, and subsequently fever. Of all the mineral acids employed, this, however, may be administered for the longest period without occasioning such symptoms. When thrown into the veins it coagulates the blood and causes death.

Modus operandi.—Administered in the very dilute state, this acid probably becomes absorbed, for it influences the quality of the urine, and sometimes communicates to the milk a griping quality. Its use is said even to be hurtful to the fœtus in utero.

Uses.—(*a*) *As a local agent* it may be employed as a caustic, an irritant, or as an astringent. As a *caustic* it has no advantage over many other agents, except that which arises from its liquid form, which, in most cases, renders it disadvantageous. For example, the difficulty of localizing it, would be an objection to its employment in the production of an issue, but would be an advantage in applying it to wounds,—such as those caused by rabid animals, or poisonous serpents, since the liquidity of the acid enables it to penetrate into all parts of the bites.

In *entropium*, or that disease in which the eyelid is inverted or turned inwards upon the eye, this acid has been applied as a caustic. In this complaint, the friction of the eyelashes on the globe is most distressing, giving rise not only to inflammation, but even ulceration of the cornea. Now when the disease is permanent, two modes of curing it have been proposed; either to remove a fold of the integument by the knife, so that, by the subsequent cicatrization, the lid may be drawn outwards—or to destroy a portion of the skin by a caustic, as sulphuric acid. The latter plan of treatment has been practised successfully by several eminent oculists, among whom I may name Mr. Guthrie and Mr. Lawrence. So also in *ectropium*, in which the lid is everted or turned outward, Mr. Guthrie has applied the concentrated acid to the

inner side of the everted lid with advantage.

Mixed with fatty matters, either lard or olive oil, sulphuric acid has been employed sometimes to occasion rubefaction—sometimes as a styptic—and lastly, as a remedy for the itch. Thus 1 part of sulphuric acid mixed with 6 or 7 parts of lard, has been employed as a rubefacient in paralysis; or applied to the skin in the second stage of inflammation of the joints, when the violence of the disease has subsided; or to wounds, to suppress hæmorrhage from numerous small vessels. Lastly, properly diluted, we employ this acid on account of its *astringent* qualities as a gargle, in ulcerations of the mouth and throat; but after using it the mouth should be carefully rinsed, to prevent the action of the acid on the teeth.

(*b.*) *Internally* we frequently employ the acid as a *tonic*, usually as an adjunct to bitter infusions. For example, in fevers, especially of the kind formerly termed putrid: when the violence of the disease has subsided, and when no marks of gastro-enteritic inflammation are present, you will occasionally find a few drops of the dilute acid may be given in the infusion of quassia, or of gentian, or even of cinchona bark, with great advantage. *To check profuse sweating* in pulmonary and other affections, whether phthisical or not, it is sometimes a valuable agent, though occasionally it fails to give the least relief. In *hæmorrhages*, as from the lungs, stomach, and uterus, it is administered as an astringent, but its efficacy is doubtful. So also in purpura hæmorrhagica it is given with the same intention, but though I have several times employed it, I have not observed any evident benefit derived therefrom. In *febrile diseases* generally it may be administered largely diluted, as a refrigerant, to diminish thirst and preternatural heat, but the vegetable acids are to be preferred. On account of its chemical properties it has been employed as an *antidote* in cases of poisoning by the salts of barytes and lead, but it is more advisable to give the sulphates, as of magnesia and of soda. In some forms of *lithiasis* it has been given with occasional advantage. But in order to place more clearly before you the cases that may perhaps be relieved by the employment of acids, I shall arrange urinary sediments in the following manner,—for I put out of the question the solid concretions or calculi, as we have at present no probable means of removing them except by a surgical operation (lithotomy or lithotrity):—

- 1. *Pulverulent* or *amorphous* sediments ....
  - (*a.*) *Lithates* (called also urates) of ammonia, soda, and lime, *tinged* by the *purpurates*, or by the colouring matter of the urine ......
    - 1. *Yellow* sediments; called by Prout, sediments of health, because they occur in the urine of healthy or slightly dyspeptic individuals, by errors of diet.
    - 2. *Red* or *lateritious* sediments, indicative of feverish, or inflammatory action.
    - 3. *Pink* sediments: these occur in dropsy, hectic fever, and visceral affections.
  - (*b.*) *Phosphate* of lime, and the triple phosphate of magnesia and ammonia; constituting sediments nearly *white*.
- 2. *Crystallized* sediments, commonly termed *gravel* ....
  - (*a.*) More or less *red*, and composed of nearly pure *lithic acid*.
  - (*b.*) *White*, composed of the *triple phosphate* of magnesia and ammonia.
  - (*c.*) *Dark blackish green*, composed of *oxalate of lime*: these are very rare.

Now you observe, from the above table, that the *white sediments* (whether amorphous or crystallized) are composed of the phosphates; while the *coloured sediments* (the dark blackish green excepted) consist of lithic acid, or the lithates. It must be admitted, however, that the colour of the sediments cannot always be relied on for distinguishing their composition, and, therefore, it is proper you should determine by chemical means to which of these two kinds of sediments the one under examination belongs. On this depends, in some measure, the plan of treatment to be adopted; for when the *white* or *phosphatic* sediments are observed, the use of the mineral acids will oftentimes be found beneficial; and the alkalies, their carbonates, and their vegetable salts, should be most carefully prohibited. On the other hand, when the deposits are *lithic acid*, or the *lithates*, the alkalies are beneficial, and the acids may be regarded as objectionable. The acids employed in the white or phosphatic deposits, are principally the sulphuric and

muriatic; the first being preferred, since it can be continued for a longer period without occasioning gastric disorder. You will, however, be much disappointed if you expect to effect a cure by a chemical mode of treatment merely, which, in fact, is to be regarded rather as a palliative than a curative means. Laxatives, alteratives, tonics, diet and regimen, &c. are among the most efficacious remedies. In *skin diseases*, especially lichen, the employment of sulphuric acid has been found beneficial.

Administration.—The *dilute sulphuric acid* of the Pharmacopœia, made of $1\frac{1}{2}$ fluid ounces of the strong acid, with $14\frac{1}{2}$ fluid ounces of water, may be given in doses of from 10 to 40 drops in any convenient vehicle. The *compound infusion of roses* is a very agreeable form of employing it. We may give of this infusion from 1 to $1\frac{1}{2}$ ounces. Another mode of exhibiting it is in the form of the *aromatic sulphuric acid*, of the Edinburgh Pharmacopœia. This compound consists of alcohol, sulphuric acid, and some aromatics (cinnamon and ginger), and is sold in the shops under the name of *elixir of vitriol*. In this preparation the alcohol is partially converted into sulphuric æther. It is given in doses of from 10 to 30 drops. In the Dublin Pharmacopœia is a formula for a *sulphuric acid ointment*, or *acid soap*. It consists of a drachm of the strong acid to an ounce of lard. The ingredients should be mixed in a mortar (of glass or earthen-ware).

Antidotes.—In the event of poisoning by the strong acid, instantly administer chalk, or magnesia, suspended in water, or whiting, or soap, or white of eggs, or gelatine, or milk. In the absence of any of the agents now mentioned, large draughts of water, or oil, or in fact any mild diluent, should be instantly administered, for a few minutes' delay may perhaps seal the fate of your unhappy patient. The case is afterwards to be treated as one of gastro-enteritis.

(b.) *Sulphurous Acid.*

History and synonymes.—Although known to the ancients, yet we are indebted to Stahl, Scheele, and Priestley, for the first accurate examination of it. It has been termed *volatile sulphurous acid*, *spirit of sulphur by the bell* (from the mode of procuring it).

Native state.—It escapes from the earth in a gaseous form, in the neighbourhood of volcanoes.

Preparation.—For chemical purposes it is prepared by mixing two parts of mercury with three parts of strong sulphuric acid, applying heat and collecting over mercury. The results are the bipersulphate of mercury and sulphurous acid.

Re-agents.	Results.
$4\,\dddot{S}$	$2\,\ddot{S}$
M	$\ddot{M}\,2\,\dddot{S}$

For pharmacological purposes, however, it will seldom be necessary to procure it in this way. By the combustion of sulphur in atmospheric air, this gas is readily obtained; and when we are about to employ it, either as a disinfectant or vapour bath, this method is always followed.

Properties.—In the gaseous state it is colourless and transparent; having a remarkable and well-known odour, incombustible, and not being a supporter of combustion. It reddens litmus and bleaches some colouring matters, especially infusion of roses. It is irrespirable, is absorbed by water, and has a specific gravity of 2·2.

Composition.—It is composed of

			Constituents.		Resulting Compound.
1 atom of sulphur	16	or by volume	oxygen = 16	& sulph. = 16	sulphurous acid =32
2 atoms of oxygen	16				
1 atom of sulphurous acid	32				

Characteristic tests.—Its odour (that of burning sulphur) is most characteristic. Peroxide of lead, with which it forms protosulphate of lead. A solution of it added to iodic acid, abstracts oxygen from the latter, and sets iodine free, which may be recognized by its producing a blue colour with starch.

Physiological effects.—It is a powerful local irritant: inspired in the pure state, it causes spasm of the glottis; but diluted with air, it enters the lungs, and occasions cough, heat, and pain. Applied to the skin, it produces heat, pain, and itching.

Uses.—It has been employed as a *disinfectant* from very remote periods, for Homer alludes to it both in the Iliad and Odyssey. In the cure of *itch*, baths of sulphurous acid gas are mentioned by Glauber, in 1659. At the Hôpital St. Louis, a very complete apparatus for the application of this remedy in diseases of the skin has been erected by D'Arcet: it is a kind of box, inclosing the whole body, with the exception of the head. The sulphur is placed on a heated plate in the lower part of the box. From ten to twenty baths, or even more, are requisite to effect a cure. Rayer, in his elaborate work on skin diseases, admits these baths are some-

times serviceable in chronic eczema, but objects to their use in scabies, on the ground of "the long continuance of the treatment necessary to relieve the disease."

As a stimulant in syncope, or asphyxia, this gas has been recommended by Nysten. It is readily applied by holding a burning sulphur match under the nose.

Antidotes. — When this gas has been respired, we may inhale the vapour of solution of ammonia. A few drops of the liquid may also be swallowed.

OBSERVATIONS ON URINARY DEPOSITS.

By R. H. Brett, Esq. M.R.C.S.

[Concluded from p. 851.]

Sediment containing Red Particles of the Blood.

I have already stated, that in some cases where the quantity of red particles is small, the urine suffers them to subside only after a considerable time, and the fluid possesses, in many cases, a greenish tinge, so strikingly analogous to that produced by biliary colouring matter, as to require means besides those afforded by mere inspection to distinguish the one from the other. This peculiar green tinge has been supposed to depend upon the ultimate blending of the peculiar red colouring matter of the blood with the yellow colour of the urine; and in certain cases, after blood has been drawn, and the usual coagulation of the red and fibrinous portions perfected, the super-natant fluid has possessed more or less of a green tinge; but I doubt whether this is to be set down solely to the admixture of red particles with the yellowish serum: for if we take dried cruor, finely powdered, and add it in variable proportions to healthy urine which is of a fine amber-yellow colour, no green tinge similar to that just alluded to can be produced. The same holds good if perfectly fresh or moist cruor be employed; if also, instead of employing urine, we make use of carefully-decanted serum of blood, or any fluid rendered yellow by colouring matter, the same state of things will be observed. I think I have observed, that when urine or serum of blood containing a small proportion of red particles suspended through or dissolved in it, has been allowed to remain for some hours, especially if the temperature be somewhat elevated, the fluid has assumed somewhat of a green tinge. This I am inclined to look upon as the result of decomposition, and probably the production of sulphuretted hydrogen, which, reacting upon the ferruginous matter contained in the blood, furnishes the green tinge in question. The following experiment in particular led me to entertain such a notion. A small quantity of colouring matter of blood was dissolved in water, sulphuretted hydrogen was then passed through the fluid; it first assumed a purplish tinge, and ultimately passed into a dingy green. Be this explanation correct or not, certain it is that mere artificial mixtures of the red particles of blood and yellow fluids are not capable of producing that peculiar green tinge which is occasionally observed in urine.

How distinguished from Bilious Urine.

Since, then, it appears that urine mixed with small quantities of red colouring matter of the blood does not unfrequently put on an appearance strikingly similar to bilious urine, it becomes a matter of first-rate importance to distinguish between them. In both cases there may be a deposit independently of the red particles of the blood on the one hand, or the biliary matter on the other, from the precipitation of some of the salts naturally existing in the urine, and which may become tinged with the colouring matter of the blood, or of the bile diffused through the secretion.

I have already observed that bloody urine always undergoes a change, more or less marked by the application of heat, in consequence of an albuminous impregnation. Now bilious urine does not undergo this change, inasmuch as there exists no albumen capable of being coagulated by heat, at least in healthy bile. It must, however, be confessed that the bile, passing through the urinary passages, might become mixed with some albuminous matter; but even in such a case, unless the latter were very considerable in quantity compared with the biliary matter, no coagulation would ensue upon the application of heat, for bile appears to possess the curious property of preventing the coagulation of small quantities of albuminous matter, even after the latter has undergone that pe-

culiar change which is produced by coagulation. This conclusion was arrived at by Powell, who instituted a series of experiments on that subject. Again, it is well known that muriatic or nitric acid, when added to bilious urine, causes, in most cases, after some time, a deposit of a green colour to take place,—a circumstance not observable in urine impregnated with red particles of blood. If the green deposit obtained by the addition of an acid to bilious urine be collected and washed, the addition of nitric acid will cause it to dissolve, with a considerable play of colours,—the green passing into various shades of blue, violet, and pink; ultimately, however, especially if the acid be in considerable quantity, or heat be applied, into yellow. This is highly characteristic of biliary colouring matter; it must, however, be remembered, that bilious urine contains that peculiar modification of colouring matter which is not precipitated of a green tint, but of a brown colour, by acids. This description of bilious urine is, however, easily distinguished from bloody urine, from the fact of its not being coagulated by heat. It sometimes happens that bilious urine yields a deposit which, when collected upon a filter, appears in the form of orange-yellow flocculi, consisting chiefly of the colouring matter of the bile. By exposure to the air, these flocculi become green; and when dissolved, which they easily are in a solution of caustic potass, give the same re-actions with nitric acid as described above. In those cases, however, where bilious urine lets fall a pretty abundant and somewhat ropy deposit, of a green or yellowish-green colour, it will, when carefully examined, be found to consist mainly of mucus, tinged with biliary colouring matter, in the same manner as mucus from the stomach is not unfrequently found of a green colour, from admixture with bile.

I have occasionally examined urine of so deep a colour as to lead to the suspicion of the presence of the colouring matter of blood or bile. In these cases the quantity voided at a time is generally small, and it might *à priori* be supposed that there was a deficiency of the watery parts of the urine, by which the fluid became concentrated; but upon examining it, comparatively with healthy urine, there has been found a positive deficiency of urea and uric acid, the only organic principle in excess appearing to be the colouring matter; there was no evidence of the presence of bile or red particles of the blood.

Creamy and Caseous Urine.

The urine has occasionally been observed of a milky colour, throwing up a creamy matter to its surface, and yielding by filtration a fibrinous residue of a reddish colour. The fluid portion of such urine is found to be coagulable by heat; at other times, however, this effect is not observed to take place. Dr. Prout has designated this *chylous* urine, and seems to consider the extraneous matter in it as imperfectly-formed blood.

Wurzer relates the case of a man who was subject to catarrhal affections, in whose urine he found a deposit having all the properties of caseous matter; there was also a deficiency of urea. In a case detailed by M. Petroz, of a woman who died in child-bed, the urine, upon examination, was found to contain caseous matter. M. Cahol examined a specimen of urine, transmitted to him by M. Alibert, physician to the Hôpital St. Louis. Having examined it by several re-agents, he found that it gave evidence of the presence of caseum. "We commenced," says he, "a series of experiments, of a comparative nature, with this substance, and the caseous matter obtained from skimmed milk. Upon subjecting each to the action of the same tests, the same results were obtained; and both yielded by distillation precisely analogous products. The urine, freed from the caseous matter, had all the chemical properties of that secretion in its ordinary condition."

Purulent Deposits.

The last urinary deposit which I shall enter upon the consideration of is the purulent. Perhaps none of the preceding are of more importance; for the existence of this substance in the urine will always lead us to suspect a very serious morbid condition of the kidney, urinary passages, or bladder, if not positive disorganization of some one or more of these structures. The difficulty of distinguishing very small quantities of pus from equally minute proportions of mucus under certain conditions, be these principles derived from whatever part of the body they may, has long been universally allowed; and although

that difficulty is far from being entirely removed, when we confine our attention to the deposit of that description, as occurring in the urine, still it is somewhat diminished; for in those cases in which we meet with it in the urine, the purulent matter is for the most part in sufficient quantity to enable us to recognize it without much difficulty, as well from its peculiar physical nature, as from the action of reagents upon it. It is nevertheless true, that we occasionally meet with organic deposits in the urine, which seem to partake of a mixed character between pus and mucus. The latter is capable of undergoing very marked changes, arising apparently in some cases from the effect of certain vital actions, in others from atmospheric exposure.

Thus inflammatory action will alter the character of a mucous secretion, rendering that opaque which, in a healthy condition, is semi-transparent; and modifying also its chemical habitudes. Mere exposure for some time to atmospheric influences will also cause a change of a sufficiently striking nature to take place. Thus mucus which was originally semi-transparent and ropy, becomes in part opaque, and appears to undergo a species of coagulation, putting on many of the characters, both physical and chemical, of coagulated albumen. A ready and unequivocal mode of distinguishing these two principles from each other has long been a desideratum among medical men; and although the remarks which are about to follow will not be found applicable to pus and mucus in whatever part of the body they may be found, still as far as the urine itself is concerned (that being the main object at present), they may, perhaps, be found adequate to the distinction.

Characters of Pus.

It will, however, be necessary, before noticing purulent matter as constituting a urinary deposit, to make some general remarks upon the nature of pus. This peculiar fluid, which is not unfrequently one of the products of inflammatory action, is somewhat viscid in character, of a pale yellow colour, with a slight tinge of green; opaque and homogeneous. It possesses no appreciable odour when cold, but when warm, and in considerable quantities, it exhales a vapour of a somewhat mawkish odour. When fresh it neither reddens litmus or turmeric paper. According to some authorities it speedily becomes acid by keeping; this, however, will depend much upon the length of time it has been kept, and the temperature to which it has been exposed. It is stated by some that this acidity is by no means permanent, soon giving place to an alkaline reaction, owing to the formation of ammonia. I have certainly found that when pus has been diluted with water, and kept uncovered in a cool place, that it has not given any signs either of acidity or alkalinity, even for days.

Pus has been considered by some as blood deprived of its red particles; and this opinion appears to me to be borne out by certain experiments, the truth of which being admitted, will form an excellent ground-work whereon to build many means of distinguishing this peculiar substance from mucus. Every one who has decolorized the cruor of blood by means of chlorine, must have been struck with the close resemblance which the colourless, or nearly colourless, fibrinous particles of the blood suspended through the water, have with those particles which are suspended through a purulent fluid diluted with water; but this resemblance is rendered still more obvious, if the fibrinous particles just alluded to be diffused through a serous fluid, such, for example, as pure serum of blood, rendered somewhat less viscid than ordinary by dilution with a little water.

Now if it can be shewn that the chemical habitudes of pus are similar to those possessed by decolorized red particles of blood suspended through a serous fluid, then I think it may be fairly conceded that the former differs only from blood in its being destitute of colouring matter, and having a less concentrated form than the latter fluid. I shall now proceed to shew that the above assumption of chemical analogy between the two fluids is not at variance with the result of direct experiment.

The two obvious ingredients of healthy blood are, its serum, or more fluid part, and its cruor, crassamentum, or more solid part. The former we know by analysis to contain a large portion of water, some albumen, and certain salts, chiefly of an alkaline nature, with a little fatty matter and extractive; these

are the most striking and important constituents of serum, and the only ones it is necessary here to enumerate. The latter consist of a substance called fibrine, colouring matter, and certain salts, chiefly of an earthy nature, with a very important metallic oxide, at least chemically considered, viz. peroxide of iron, together with some fatty matter. If pus be allowed to remain at rest for some time, the opaque particles subside, and a clear fluid remains at top. This last, when carefully removed and examined, is found to be coagulable by heat even below that of boiling water. The stronger acids also coagulate it. If the watery part be separated from the coagulated portion, it is found to yield by evaporation and subsequent incineration a saline residue, in no respect differing from that which the serum of blood yields under similar treatment. A little fatty matter is also capable of being separated from the serous part of pus. In all these respects it bears a strict analogy to the serum of blood, the only difference being that one is a much more concentrated albuminous fluid than the other. That portion which is opaque and insoluble differs in no respect, when collected and dried, from decolorized red particles, and may, therefore, be called the fibrinous portion of pus. Water possesses no solvent action over it; neither do the diluted acids. Caustic potass is capable of dissolving it with the assistance of heat; and it yields by incineration a fixed residue, containing a small portion of oxide of iron and earthy phosphatic salt, similar to that found in the fibrine of blood. We are also able to remove a little fatty matter, by boiling the insoluble particles in alcohol before incineration. It is clear, then, that not only is the serous, or fluid albuminous portion of pus, very similar in chemical constitution to that fluid when separated from the other solid parts of blood, but that the solid and insoluble particles are not different from the red particles of blood which have undergone decolorization.

It is not my intention in this place to make any reference to the numerous experiments, microscopic and chemical, that have at different times been instituted on purulent matter. Darwin, Pearson, and Everard Home, are the principal writers on this subject in this country; but their experiments, however clear and convincing they may appear at a first perusal, have not, when repeated by others, afforded similar results; besides, it is my intention to confine my remarks as much as possible to the consideration of purulent matter as found in the urine.

The following action of reagents on pus is different from that observed in the case of healthy mucus, and apply to pus and mucus generally:—

1. Strong acetic acid, when added to pus in the proportion of four parts acid to one part pus, does not appear to produce any more effect on the purulent fluid than the same bulk of mere water.

2. The addition of the same quantity of acid to healthy mucus causes it to contract in bulk, still retaining much of its transparency, and appearing like a membranous substance, or semi-gelatinous mass, diffused through a perfectly pellucid fluid. Mucus, however, which has been exposed for some time to atmospheric influences, as well as that which has been altered by inflammatory action, is not capable of undergoing this characteristic change by means of acetic acid.

3. If an equal bulk of concentrated sulphuric acid be added to pus, an imperfect solution of a deep brown colour, bordering upon purple, is produced. Upon dilution with water the colour is entirely discharged, and the fluid remains troubled from the diffusion of opaque particles through it, having an appearance precisely like pus diluted with a considerable quantity of water.

3. If mucus be treated in a similar way with concentrated sulphuric acid, the colour produced is a pale brown, very much less deep than in the instance above noticed. Dilution with water discharges the colour. The resulting fluid is not opaque, however, as is the case with pus.

4. If pus be boiled with three or four times its bulk of strong nitric acid, a yellow coloured solution is obtained: if this solution be evaporated, so as to get rid of the redundant nitric acid, a yellow viscid mass is obtained. The heat should then be continued so as partially to char the syrupy mass. Water should then be added, and a drop or two of nitric acid, so as to render the fluid somewhat acidulous. The whole should then be evaporated to a small bulk, and filtered. The fluid which comes through is still yellow, and somewhat acid. The addition of a drop or two of a solution

of ferrocyanate of potass causes the whole to become of a deep bluish-green colour, from the formation of prussian blue by the action of the salt of potass on the per-oxide of iron, removed from the pus by the agency of the nitric acid.

5. A given bulk of the yellow acid fluid, obtained as above described, was treated with two drops of ferrocyanate of potass.

6. The same bulk of pure water was rendered very acid by means of nitric acid, much more acid, indeed, than the yellow fluid just noticed, and two drops of a solution of ferrocyanate of potass added.

7. The same bulk again of pure water was rendered yellow by means of carbazotic acid (the yellow principle obtained from indigo), so as to resemble in colour the yellow fluid, 5. Two drops of ferrocyanate of potass were also added.

In Exp. 5 the fluid became instantly of a deep bluish-green colour; and after a short time yielded a precipitate of a distinct blue colour.

In Exp. 6 the fluid was not altered until some time had elapsed, and then it became of a pale blue colour.

In Exp. 7 no alteration was produced in the fluid at first; it afterwards became of a light green colour, yielding, however, no precipitate.

These experiments were made for the purpose of removing any source of fallacy that might have arisen from the nitric acid, in Exp. 5, producing a blue colour with ferrocyanate of potass, independently of any iron which might have existed previously in the fluid; for the stronger acids, when added to ferrocyanate of potass, are capable of partly decomposing the latter, and causing, after a time, a precipitation of prussian blue. Exp. 6, however, shews that the acid produced no such effect until after some time, whereas in Exp. 5 it was produced immediately.

Exp. 7 also shews that a fluid equally yellow, and more acidulous, did not produce the same effect with the same quantity of ferrocyanate of potass, even after some time. It is clear, therefore, that the fluid in Exp. 5 must have contained per-oxide of iron, and that that metallic oxide was obtained from pus. Since mucus when treated in a similar way gives no evidences of the presence of iron, I think that where we can obtain a sufficient quantity of matter for operation, that this mode of examination would be found, if not a decisive, at least an important auxiliary test for distinguishing pus from mucus. I shall now conclude the subject of urinary deposits by describing the appearance of the purulent deposit, as it is found in the urinary secretion.

Tests of Purulent Urine.

Urine containing pus will almost invariably be found of a pale colour; it will be found sometimes acid, at others alkaline; and although somewhat, is not nearly so prone to undergo decomposition as is observed in some of the worst forms of the phosphatic deposit. If urine of this character be allowed to remain at rest, the purulent matter subsides after some time, having a greenish yellow tint, which is highly characteristic of it. This deposited matter is ropy, and capable of being, in some cases, drawn out into threads. When thrown upon a filter, it appears in the form of a perfectly opaque coagulum, of a greenish-yellow colour, very different from ordinary mucus, as found in the urine. When treated with three reagents, which were noticed when speaking of pus generally, it behaves precisely in the same way towards them.

The urine from which this deposit has taken place will be found to be invariably albuminous, coagulating by heat and by nitric acid. Tincture of galls, corrosive sublimate, and alum, all cause either a precipitate, or manifest turbidity. This albuminous impregnation of the urine is depending, I believe, on the serous portion of the purulent matter being diffused through the urine, the deposit consisting of the insoluble opaque particles, mixed with a larger or smaller proportion of mucus.

ON SECONDARY UTERINE HÆMORRHAGE.

By John Roberton,

One of the Surgeons to the Manchester Lying-in-Hospital.

The use of the term "secondary" in this connexion is warranted by such circumstances as these:—A woman who perhaps has had a favourable confinement, the placenta having been naturally thrown off, accompanied with no

undue discharge of blood, is seized suddenly and unexpectedly, after the lapse of one, two, three, or even four weeks, with uterine hæmorrhage. Under this head I do not include the menorrhagia lochialis, or constant draining of blood; neither that description of hæmorrhage which, commencing at the time of, or very soon after, the expulsion of the placenta, returns repeatedly at short intervals (generally attended with more or less after-pains) for days or even for weeks; as little do I include floodings caused by portions of the placenta suffered to remain in the uterus.

Although secondary uterine hæmorrhage is not of frequent occurrence, I imagine few in extensive practice but must have seen it. It has, however, obtained less notice in works on midwifery than might have been expected. Even in Mr. Ingleby's Treatise on Uterine Hæmorrhage, (the latest and the most complete on this subject we possess,) it is alluded to chiefly in an incidental manner. Under the head of "hæmorrhage with a firm contraction of the uterus," the writer intimates having witnessed, in several instances, blood discharged "in quantity sufficiently great to reduce life to immediate danger at so late a period as three weeks after delivery, even when the uterus is apparently *small and well contracted**." Again—"I have used the plug with the best effect in an hæmorrhage imminently dangerous, as late as fourteen days after delivery, the uterus being *firmly contracted*†." In another place he remarks—"I could add several striking cases in confirmation of the efficacy of superacetate of lead in uterine hæmorrhages arising at late periods after delivery‡." In the elaborate work of A. C. Baudelocque, on the Internal Hæmorrhages of the Uterus, I cannot discover that what I have defined as secondary uterine hæmorrhage is at all distinctly noticed§.

Perhaps it is this description of secondary hæmorrhage that Burns refers to in the following passage: "It may happen that from some agitation of mind, or morbid state of body, the uterus may not go regularly on in its process of contraction or restoration to the unimpregnated state. In this case the cavity may be filled with blood, which forms a coagulum, and is expelled with fluid discharge. The womb may remain stationary for a considerable time, and the coagula be successively expelled with slight pains and no small degree of hæmorrhage. These symptoms very much resemble those produced by the retention of part of the placenta, and cannot easily be with certainty distinguished from them, &c." p. 481. Here, however, nothing is said as to *the length of time which has elapsed after delivery*, when the uterus begins to expel coagula and fluid blood. In the above work of Baudelocque there are some interesting remarks on a kind of bloody discharge, which this writer supposes to arise, partly from the womb after delivery chancing to lie too obliquely to permit the due escape of the lochia, and partly from deficient uterine contraction, owing to which clots form in the uterine cavity; the effect of such accumulation being severe after-pains, which often annoy the patient for many days, until the uterus is emptied. To prevent this state of things, Baudelocque advises the accoucheur to carry two fingers into the womb after delivery, "pour s'assurer de l'etat de sa cavité, et la débarrasser des corps etrangers qui peuvent y être restes." Adding, "cette pratique est celle que suit M. Deneux depuis plusieurs annees, et a laquelle je ne manque jamais d'avoir recours."—Pp. 263 and 264.

Of two or three of the earlier cases of this species of flooding which came under my care I do not possess notes: but of a few I have memoranda, scanty indeed, yet perhaps copious enough to convey some notion of the nature of the accident, which is further and better illustrated by notes of cases kindly and liberally furnished me by several of my friends and colleagues.

CASE I.—April, 1829. Mary Noble, a patient of the Lying-in-Hospital, had a favourable labour, attended by a free but not alarming discharge of blood. On the fourth day after delivery she felt herself so well as to be induced to remove her binder, and begin attending to her household affairs. From this period till the end of the fortnight, things seem to have gone on favour-

* Ingleby on Uterine Hæmorrhage, p. 227.

† Ibid. p. 247.

‡ Ibid. p. 255. Allusion is made to this kind of hæmorrhage in Blundell's Lectures on Midwifery, London, 12mo. p. 102; in Campbell's Introduction to the Study and Practice of Midwifery, p. 308; in Denman also, p. 442.

§ Traité des Hæmorrhagies internes de l'Utérus, &c. Bruxelles, 1832.

ably; but at this time, as she was seated by the fire, a copious discharge of blood took place, producing syncope. On reaching her shortly after I made a careful examination *per vaginam*, without, however, detecting any circumstance calculated to explain the cause of the hæmorrhage. The uterus did not strike me as being larger than it ought to be, and the os uteri was soft, and as far as I could judge natural. The treatment consisted in strict confinement to bed, small repeated doses of ergot of rye, and laxatives. There was no return of the hæmorrhage. From a later entry I find that this patient became dropsical; and that she ultimately recovered.

Case II.—Nov. 5th, 1829. —— Mellor, aged 23, a fortnight confined of her first child, very imprudent in the liberties she has allowed herself as to both diet and exercise. Last night a discharge of blood took place from the vagina that nearly extinguished life. To-day there has been a further gush. The pulse is feeble and rapid, and the mind is barely coherent. On examining by the vagina I find the os uteri open enough to admit the finger, and the uterus itself larger than is usual so late after delivery. Ergot of rye was given every fourth hour, in doses of 6 grains; a sponge plug was passed, a laxative was ordered, and the recumbent position strictly enjoined. The patient slowly recovered, without having had a return of the hæmorrhage.

Case III.—May 1st, 1833. — Kerney, aged 26, seven days delivered of her second child. The labour had been favourable, followed by some, but not a profuse discharge. Was doing well till 5 o'clock this morning, when, in getting out of bed to make water, a large hæmorrhage took place, which the attendants estimate at three quarts, but which I have reason to believe was under a third of that quantity. The patient appears feeble and reduced. She informs me that a similar accident occurred in her former confinement, which happened about a year ago, and then the flooding occurred nearly a month after delivery. The os uteri is a little open, but I cannot say that the womb is expanded. Subsequently the hæmorrhage returned twice, but less profusely than in the first instance. The super-acetate of lead was freely administered, and the patient (how far owing to this medicine I will not say) had a favourable recovery.

Case IV.—Nov. 25, 1833. Mrs. W., the mother of several children, enjoying good general health, but who is lame from rheumatism, was brought to bed on the 29th of October, that is, 27 days ago; the labour unattended with any degree of hæmorrhage. Her recovery had been so far favourable, and she had left her bed-room. Yesterday, while seated by the parlour fire, she discharged a clot of blood the size of an egg, followed by several other clots, when she became faint, and in this state was removed to bed. There was no return of hæmorrhage.

Case V.—Dec. 11th, 1835. — Inglesby, aged 27, delivered of her first child nine days ago. The labour was in every respect natural, and she was doing well till to-day, when, after a shivering fit as she sat by the fire, a considerable hæmorrhage issued from the vagina, chiefly in the form of clots, producing faintness and vomiting. She was immediately put to bed. Some degree of hæmorrhage continuing, four ten-grain doses of ergot were given at intervals of half an hour, seemingly with effect; for the patient, who was not much weakened, soon recovered.

The following case occurred in the practice of Mr. Fawdington: these are his notes.

Case VI.—Mrs. S. H., 31 years of age, spare in person, and delicate in health, was delivered of her first child, September 3d, 1835, after a natural and rapid labour, the placenta being expelled without any assistance in about half an hour, unattended by any sanguineous discharge worth notice.

Up to the 10th day after delivery, viz. September 14th, my patient had done very favourably. Her strength and spirits had been good, the lochia natural, the secretion of milk moderate; and she had latterly sat up in her bed-room a few hours daily. But in the course of this day she began to complain of a sense of bearing down, and of not feeling herself quite well; in consequence of which she was desired to keep her bed. In the course of the following night coagula were expelled from the vagina, amounting, it might be, to about

a pound. The next day, although she kept strictly in her bed, there was some trifling hæmorrhage, but the ensuing night it came on with alarming violence. During the ten following days, that is till the 24th of September, although various means were adopted to stay the discharge, it continued to return at intervals, until my patient was in a state of the most deplorable exhaustion—nearly pulseless, the extremities cold, the mind at times wandering, and she incapable of enduring the slightest change of position, such as in voiding her urine, without syncope. Indeed, for several days her urine had to be statedly drawn off.

After the cessation of the hæmorrhage, three weeks elapsed before my patient could leave her bed. She, however, slowly, but perfectly recovered.

Mr. Windsor furnishes me with Cases 7 and 8.

Case VII.—June 28th, 1835. Mrs. H., the mother of several children, was seized on the sixteenth day after delivery (she was confined on the 12th of June) with profuse hæmorrhage from the uterus. Previously to this time she appeared to be doing very well; the labour had been propitious, and there had been no trouble with the after-birth. The lochia and lacteal secretion were natural. She complained at times of pain in the uterine region, not of the nature of after-pains.

Mild opiates and aperients were prescribed, and cloths wrung out of vinegar and water were applied to the external parts; by which means the hæmorrhage abated for a time.

But two days after, having moved rather too much, the discharge returned so copiously as to induce alarming syncope, with its usual attendants; so that her life was apparently in great danger. It happened that I was in the house just as the hæmorrhage came on. The means used on the former occasion were now repeated; and added to these was the introduction of a sponge plug, moistened with vinegar and water. The pulse being scarcely perceptible, and the countenance pale and exsanguineous, wine was freely administered, with decidedly good effect. Afterwards she had ergot, in doses of fifteen grains, repeated every six hours.

By this plan the patient gradually recovered, and the hæmorrhage did not return, at least to any considerable extent. The plug was changed every, or every other, day.

July 28th.—Is gradually recovering; has a frequent pulse, some headache, and slight œdema and pain of legs. The sponge plug being now only a little stained, it was finally withdrawn to-day—five weeks and two days after her confinement.

August 28th.—Has had no return of the catamenia; œdema gradually diminishing; general health pretty good. The infant has to be suckled by a wet nurse.

Case VIII.—Dec. 31st, 1835. Mrs. B. was confined of her second child after a few hours' labour. The placenta was discharged naturally, without any unusual flow of blood.

On the 10th of January (till which time she had been doing well), she was seized rather suddenly, after going into the next room to see a sick sister, with severe uterine hæmorrhage. I visited her not long after, and found there had been a profuse discharge of blood, and large coagula were lying about her. The os uteri and vagina were in a very relaxed state; she was almost pulseless, pale, and exsanguineous. A plug was used, and the same means as in the former case. The use of the plug was persevered in only for a few days. She recovered more rapidly than Mrs. H., without any troublesome sequelæ, and is now perfectly well.

Case IX.—(The notes furnished by Dr. Pendlebury.) Mrs. H., aged 20, lusty, but not robust, delivered of her first child on the 13th of August, 1835, after, as I was given to understand, a favourable labour, of about six hours duration. The after-birth, too, I also learnt, was naturally expelled, without hæmorrhage, and the lochia, and the secretion of milk, were duly established.

It was not till the tenth day after delivery that any unpleasant symptom appeared. On this day she had sat up talking too much with her friends, and had also suffered much anxiety respecting her baby, which was drooping, and not likely to live. In the evening, before returning to her chamber, she suddenly discharged a quantity of coagula, became faint, and had immediately to be put to bed. In the course of the night the discharge returned repeatedly; and

once, as her husband, who was her accoucheur, informed me, she fainted away.

On the following day (the eleventh from her confinement), I saw her for the first time. A degree of hæmorrhage continued, returning at short intervals; and this state of things varied little throughout the two following days, blood being discharged, sometimes profusely, both fluid and in clots. The countenance was blanched, the pulse weak and rapid, and on one occasion the mind was observed to wander.

On laying my hand on the lower abdomen, I thought that the uterus was too much expanded. The treatment consisted in keeping the patient in the recumbent position in bed; in giving, in the first instance, brandy and laudanum; and in causing cloths, dipped in cold vinegar and water, to be applied over the abdomen. The ergot also was ordered, in small repeated doses. From this period the case, upon the whole, went on favourably; only, at the end of another fortnight, she parted with a few clots. Her health is now established, and she is again pregnant.

Case X.—(The notes furnished by Mr. Mellon). Mrs. M., 28 years of age, stout and leucophlegmatic, was confined of her first child December 25, 1835. The labour was rather tedious, but natural; and the placenta was thrown off in about twenty minutes, without flooding. The uterus afterwards appeared to be well and firmly contracted. The secretion of milk was abundant, and the lochial discharge quite moderate. In a few days she could with comfort sit up in bed, and on the eighth day she sat up in a chair for about five hours. So far, there had been no unpleasant occurrence. In the evening of this day, however, she complained of a weight in the sacrum, and a sense of coldness. Suddenly, about three o'clock the following morning, she was taken with alarming hæmorrhage: at a guess, I should say, from the quantity of clots I was shewn on my arrival, that she must have lost at least a couple of pounds. The pulse was small, and scarcely to be counted; the face extremely pallid, and the surface cold. I had the pelvis raised, the temperature of the room lowered, and I gave an opiate and a mixture containing the sulphate of magnesia. The utero-abdominal tumor was to be felt somewhat enlarged. At the end of an hour I left the patient: there was still a slight discharge, but no considerable return happened; only two days thence she discharged a pale clot. Her recovery was slow, and she has since had profuse leucorrhœa.

Concerning the foregoing ten cases of uterine hæmorrhage, it is worthy of remark, that in none had the labour preceding been severe; nor does it appear that in any the placenta was extracted by the hand, or that there was much hæmorrhage accompanying, or immediately following, the expulsion of the placenta. In one case the hæmorrhage occurred on the seventh day after delivery, in one on the ninth, in two on the tenth, in one on the eleventh, in two on the fourteenth, in one on the sixteenth, and in one on the twenty-seventh. In six of the ten cases there was a single attack only of hæmorrhage; in the remaining four, hæmorrhage occurred oftener than once.

My observations in the way of comment shall be few. The form of flooding now under consideration is sometimes troublesome to manage, as may be gathered from several of the preceding cases. In a case which was under my care a number of years ago, but of which I am not in possession of notes, the hæmorrhage returned again and again for several weeks, until I despaired of the patient's life. When, by rest and other means, I flattered myself that the risk of flooding was over, no sooner did she begin to sit up than it was renewed. I have never myself witnessed an instance that ended fatally, but my very experienced friend, Mr. Windsor, has favoured me with such a case, in the following brief note:—"About fifteen years ago, I was hastily summoned to a woman (not a patient of mine), in Bradford-street, who I learnt had been confined about a month. I immediately went to visit her, but on my arrival found she was dead; which was owing to a sudden and great hæmorrhage from the uterus, that came on as she was walking across the floor."

When death occurs, as in this instance, it is of course impossible to tell, unless from the evidence of a post-mortem inspection, whether the hæmorrhage may not have depended on local

disease of the uterus. The following case, with which I am favoured by one of my colleagues at the hospital, Mr. Clough, illustrates this remark, and will, I venture to think, be read with interest:—

"Mary Powall, æt. 25, of a delicate habit of body, was delivered of her third child on November 4, 1834. The case was, I believe, a hand presentation. Turning was easily effected, but, in extracting the child, the head was incautiously allowed to catch upon the brim of the pelvis; the face being directed rather forwards towards the pubes, the chin resting upon that portion of the bone above the left obturator foramen. This position of the head was, after a time, rectified, when it almost immediately descended into the pelvis, and was expelled rather quickly by the natural efforts. The placenta was expelled without any unusual symptoms. The patient had not much uterine discharge succeeding her labour, but she soon began to complain of pain and tenderness on pressure in the left hypogastric region, for which she was ordered between forty and fifty leeches. Her pulse was never much excited, nor had she any vomiting. The tenderness and pain of the abdomen did not entirely subside, but was confined to a small part of the left hypogastric region. There was no distention of the abdomen, and the bowels were pretty regular. After the first four days she seemed to be recovering well, when on the 8th day she was seized with severe vomiting, and towards evening a sudden and very copious flooding came on. This continued until morning, large clots escaping: the quantity lost I should think could not be less than two or three pounds. I saw her early the morning after (the ninth day after her confinement); the hæmorrhage had then ceased; her extremities were cold; there was death-like paleness, and the pulse was hardly perceptible. The hæmorrhage had completely soaked through the bed, and escaped on the floor. The belly was not tumefied, but there was some degree of tenderness, and there was vomiting. Brandy was administered, and in the course of an hour or two she seemed a little revived; the hæmorrhage, however, returned in the evening. She took the acid infusion of roses, with the tinct. opii, and was kept strictly quiet. On the 10th day she seemed a little improved, but in the evening the flooding again returned to an alarming degree. On the 11th day very low. Ordered pulv. secal. cornut., to take wine, and to have ol. ricini. 12th day, vomited the powders; pulse small, and feeble. She lived until the 18th day. There still was occasional hæmorrhage, great prostration, sordes on the teeth, furred tongue, and mucus in the throat: no pain of abdomen for the last few days, except when pressure was made, but the vomiting continued more or less until she died. Super-acetate of lead, and opium, were given, without any effect.

Postmortem inspection.—The peritoneal surface of all the viscera perfectly healthy, but very much blanched. The bladder somewhat distended with urine, and the uterus not so much contracted as is usual. Near the neck, on the left side, and between the folds of the broad ligament, there was some appearance of extravasation: and a sac partly filled with bloody pus was opened, which sac communicated by a large aperture with the general cavity of the uterus. On laying open the interior of the uterus, there was the appearance of a deep excavation or ulceration, capable of readily admitting a finger or two, leading to this sac. The other parts of this organ were perfectly healthy. The uterus was shewn to some of my professional friends, one of whom considered the excavation in question as an abscess; but two or three others, besides myself, looked upon it as a partial rupture of the organ, the opening communicating with the general cavity of the uterus being too large for an abscess to have existed there.

Madame Boivin mentions a patient who, after a difficult labour, caused by deformity of the pelvis, was taken with hæmorrhage on the twenty-second day, and on the thirtieth died, from a return of the same. On inspection, it was found that an abscess, collected in the neighbourhood, had pierced the vagina; and in so doing opened a varicose sac formed by one of the lumbar veins, and thus established a communication directly with the vena cava*.

This form of uterine hæmorrhage, it is to be remembered, is comparatively of rare occurrence, happening, probably,

* Mémoire sur les Hemorrhagies Internes de l'Uterus, page 139.

not to more than one in several hundred puerperal women. Perhaps the following remarks may tend to elucidate its nature.

The uterus pours forth a periodical secretion, which is not blood, but a fluid *sui generis*; nevertheless, it is nearer blood in its qualities, and is produced far oftener mixed with real blood, than any other secretion whatever. Hence in certain women the transition from menstruation to a bloody discharge is easily occasioned by a variety of causes. I remember a female servant, habitually liable to copious menstruation, who could not lift a heavy weight, nor work the pump to draw water, without bringing on the menstrual discharge, or perhaps I should rather say a degree of flooding; yet she was healthy, for she married, and has had a number of children. Other instances similar to this I have seen, and they are far from uncommon: they tend to show how readily, in some women, blood is poured out by the uterus,—a fact which leads me to remark, that secondary uterine hæmorrhage is probably allied in its nature to menorrhagia, only the discharge is in general more copious, on account of the comparatively greater size of the uterine vessels, and the greater readiness with which the uterine cavity admits of expansion in the puerperal than in the unimpregnated state. I doubt if it will do to ascribe this form of hæmorrhage solely to a relaxed uterus,—that is to say, to the uterus contracting too tardily in its transition from the puerperal to the ordinary condition; for where is the convincing evidence that *prior* to the hæmorrhage such relaxation really exists? After the hæmorrhage, which mostly consists both of clots and fluid blood, has burst forth, the uterus, it is true, is commonly to be felt enlarged in volume; but similar, although slighter enlargement, is often to be detected after profuse hæmorrhage from the uterus not succeeding parturition, such increase of bulk being, in the latter instance, and generally, I am inclined to think, in the former also, the effect of distention caused by the blood having been more or less accumulated in the uterine cavity. As little will it be satisfactory to attribute the occurrence of secondary hæmorrhage to the imprudence of patients in forsaking too early the recumbent position; for in truth nine out of ten of the wives of the operative class are up and stirring about by the seventh or eighth day after labour, and that (be the other ills which result from such a practice what they may) without the production of hæmorrhage.

I regret that the state of the circulation preceding the hæmorrhage did not receive more attention in taking down notes of the cases, for this is an important particular. Respecting two of the cases, it is noted that there was a feeling of chilliness previous to the attack, indicating, probably, a febrile state. Upon the whole, to dismiss the matter, I incline to think, although I desire to be understood as not speaking with much confidence, that this form of uterine hæmorrhage depends in a considerable degree on an hæmorrhagic diathesis, whose manifestation, in the discharge of blood from the uterus, is determined by the peculiar condition of that viscus in the puerperal state *.

With reference to methods of treatment, perfect rest in the recumbent position is essential; compression of the abdomen ought to be made by means of a well-adapted flannel binder; in the outset opium is useful; the plug is sometimes necessary; and the ergot of rye, in small repeated doses, I regard as the most important remedy of all. The diligent administration of alterative and aperient medicines is of very great importance, not in this kind of hæmorrhage only, but generally in the hæmorrhages attendant on abortion. As a tonic, I prefer to every other the sulphuric acid. In order to perfect recovery, such patients need a temporary removal from family cares and duties, the benefit of a pure air, judicious dieting, and in most cases exemption, wholly or in part, from the drain of lactation.

Manchester, Feb. 26, 1836.

* Since writing this paper, I have perused Dr. Montgomery's very instructive communication, in the 23d number of the Dublin Journal, "On some peculiar forms of Relaxation of the Uterine Tissue." This writer's cases and remarks refer chiefly to an extremely relaxed state of the organ resulting from abortion, which exposes the patient to profuse hæmorrhagic and leucorrhœal discharges. It occurs "most frequently after early abortions, sometimes after delivery at the full time, when there has been profuse hæmorrhage, and sometimes as the result of protracted undue lactation." How far several of the cases of hæmorrhage I have detailed are to be attributed to such a condition of the uterus as Dr. Montgomery describes, I will not now attempt to discuss. I with pleasure, however, direct the reader's attention to the communication in question, which deserves a careful perusal.

STATISTICS OF ST. MARYLEBONE INFIRMARY, FOR THE YEAR ENDING DEC. 1, 1835;

With Observations.

By John Clendinning, A.M. & M.D.

The Marylebone Infirmary has been within the last ten or twelve months the subject of several communications to the Medical Gazette. But the author of those communications, and of this, has reason to believe that, in a statistical point of view, a review of the whole year will be found to present advantages and interest sufficient to justify its publication, even at the risk of partially repeating matter already in print. He conceives that the facts of the late year, contrasted with and illustrated by those of several preceding years, for which he is now in possession of numerous tabulated data, must possess some interest for such as concern themselves about medical statistics. The author, therefore, feels happy to be at length enabled to redeem his pledge, given in his summer's Report of the Diseases of Marylebone, to furnish a medico-statistical account of several recent years' experience at the Marylebone Infirmary. The author purposes first to state the facts of the past year, and afterwards to offer such facts of former years, or from the experience of other institutions, as he may possess, and think proper for proof or illustration.

At the Infirmary the total of "Doctors' orders," or applications for medical relief from out of doors, and exclusive of the Workhouse population, for the year ending December 1, 1835, amounted to 3918: of these 751 were admitted into the wards, and the rest prescribed for by the resident surgeons-apothecaries, at the Infirmary; or visited by them at their own homes, if unable to attend at the out-patients' room. Add to the preceding, 1300 admissions from the Workhouse, and the total of sick, in and out, for the year, is 5218.

To the preceding I may add, that the Workhouse contains 214 beds, in fifteen convalescent or infirm wards, occupied at present by 226 persons—aged, epileptics, imbeciles, paralytics, or lying-in women. But I have not been able to procure any further data respecting that portion of the parochial establishment.

The admissions into the Infirmary for the year ending December 1, 1835, have been 2051; of these, 1256 were entered of the physicians' wards, and 795 of the surgeons'. The particular ages and diseases of the patients admitted will be found below, with the exception of about 150 cases of children admitted into the physicians' wards, and of about 30 admitted into the surgeons' wards, whose diseases or ages have not been recorded. Of those, the majority might be considered rather as transitory inmates than patients, their ailments having been too slight to require hospital assistance in most instances; some also having had no ailment whatsoever, being children thrown on the parish, and *in transitu* to the Workhouse schools, but placed in the Infirmary for previous medical examination. All those cases are unavoidably omitted in the table of admissions, and most of them in the table of ages, but they are all included in the other calculations.

The greatest number in the house at one time, during the year, was in February, in the second week, when there were 110 physicians' cases, and 122 surgeons'. The least number in the wards happened in September, the second week, when there were but 65 medical, and 71 surgical patients. The average daily population was 203; viz. 108 physicians', and 95 surgeons' cases.

It will be observed that the author's *annus medicus* begins with December 1, rather than the first of the civil year. His reason has been, that the solstices and equinoxes, the middle points of the seasons, physically speaking, though not strictly coinciding with the means of the medical seasons, yet on the whole differ from them not very widely, and principally by falling somewhat later in the year; so that without any important error, the 1st days of January, April, July, and October, may be assumed for medico-statistical purposes, as the middle points; and the last days of February, May, August, and November, as the *termini* of the seasons. Such an arrangement, whether correct or not, at all events accords sufficiently well with what he knows of medical statistics.

Admission Table, from 1st December, 1834, to 1st December, 1835, Marylebone Infirmary.

.... 50 .. 60	51		305

Observations.—The preceding differ considerably in several respects from the results of former years. The admissions are less, and the average population, and average stay in the house, are less, but the deaths are more, than the corresponding averages of the last five years, ending January 1, 1835. For that period the annual average of admissions was 2260; viz. 1260 medical, and 1000 surgical cases; and the average daily population was 213. The average annual mortality was 289—the average stay in hospital was 34·2 days—and the proportion of deaths to days of sickness : : 1 : 261; so that, for the year ending December 1, 1835, the mortality has surpassed the five years' average by more than 1-7th, and the average stay exceeded the corresponding five years'

average by nearly 1-3rd; while the days of sickness fell short of the five years' average by 2-5ths, being to the deaths : : 150 : 1 instead of : : 261 : 1. The mortality of the past year was then, on the admissions, 15 per cent., instead of 12·50 per cent., the average for the last five years. That considerable increase of mortality seems owing *indirectly* to the circumstances that the number of physicians' patients has not materially diminished, and that the decrease has principally happened in the surgical population; and *directly*, to an absolutely increased number of some of the more intractable diseases in the wards of the physicians. The mortality of the surgical wards was, for the last year, 25; or about 3·59 per cent.; so that the diminution on the surgical population of about 1-5th, as compared with the average of the five years ending the 1st of January last, has diminished the gross mortality by 1-50th part only; while there has been a considerable increase of the items "phthisis" and "morb. chron. cordis" on the medical side; the annual average for five years for the former having been, according to the house-surgeon's journal, admissions 127, deaths 86; and for the latter, admissions 38 per annum, and deaths 16. Whereas for the year ending December 1, last, the admissions for "phthisis" were 132, and deaths 101; and for "morb. chron. cordis," the admissions were 50, and deaths 26. No doubt something may depend on changes of officers, and of official opinions and nomenclature, more especially with respect to "morb. chron. cord.," and, in fact, I observe that within the last few years the item "*dropsy*" in the official journals has gradually been subsiding, and, together with *asthma*, giving place rapidly to the formidable item, "morb. chron. cord.," or to "bronchitis chron." Yet I think, after having made all proper allowances, something still remains to be placed to the account of the disease last mentioned; while, with regard to "phthisis," the most obvious, and long, and universally-known *rational* signs, sufficiently distinguish its advanced stages, in a vast majority of cases, to the least discriminating observer; so that I can have no hesitation in placing to the credit of 1835 the whole of the difference between the average mortalities of the last five years from "phthisis," and the mortality of that year, viz. 15, which alone will reduce last year's mortality rather below the annual average since 1831. But though in this way the difference between the gross mortalities may be accounted for, the differences between the times of residence in hospital, and the ratios of deaths to days of sickness, remain apparently unexplained, or at least not clearly accounted for; for in former years the gross mortality was less, and the average daily population, and average stay, and ratio of sick days to deaths, were greater; so that there must have been something additional in the diseases or other circumstances of the sick, to cast the scale against the late year. One cause may possibly be the diminution of the Workhouse population. Those have the "entree" into the Infirmary without "Doctors' orders," or overseers' permission, and have often gained admission, although in reality not labouring under dangerous ailments. That diminution appears, from an official statement before me, to have amounted to about one-tenth (from an average of 1058 to that of 940) since the full practical establishment of the new Vestry Bill; and that diminution in numbers in the Workhouse has increased, not diminished, the supply of sick to the Infirmary, as I apprehend, in this way. The really necessitous have submitted to the improved discipline,—the idle and able-bodied only have retreated. The result has been an increase in intensity of the mortality of the adult admissions from the Workhouse, as compared with other years, or with the mortality of the admissions from out of doors, or the parish at large. Another cause is, I have no doubt, a larger admission of children with slight ailments, such as catarrh, ophthalmia, lepra, scabies, &c. contracted in the play-ground, &c. of the Workhouse; for on referring to the return last alluded to, I find that for five years the proportion of boys and girls in the Infirmary, or persons between extreme infancy and puberty, has been pretty steadily increasing: so that from an average of less than 40 daily, in 1831, they have now reached 80 and upwards.

[To be continued.]

INJURY OF THE SPINE:

LIGAMENTS RUPTURED — VERTEBRA DISPLACED—NO PARALYSIS—RECOVERY.

To the Editor of the Medical Gazette.

SIR,

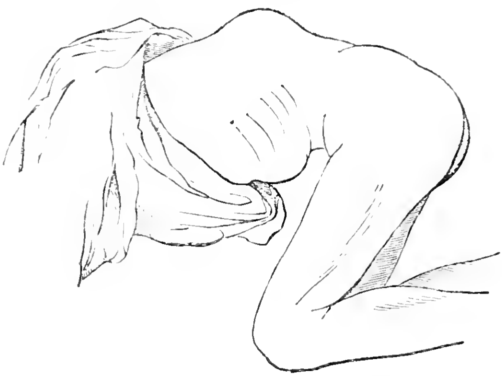
THE case of injury of the spine related by Mr. Stafford to the Royal Medical and Chirurgical Society, and reported in the last number of your Gazette, resembles a case which occurred some years ago in the Middlesex Hospital, and of which I have preserved the notes and a drawing. Perhaps these may be interesting to your readers.

I have the honour to be,
Your obedient servant,
ALEXANDER SHAW.

10, Davies Street, Berkeley Square,
29th Feb. 1836.

John Barnes, aged 32, a bricklayer, was admitted into the hospital, 18th August, 1828, having fallen from a scaffolding about thirty feet high. He was insensible for some time: when he recovered he was bled to sixteen ounces; and was brought to the hospital an hour and a half after the accident.

He lies in bed with his body much bent: at the lower part of his back there is an angular projection, which, on examination, is found to be produced by the displacement of the last dorsal and first lumbar vertebræ; the tumefaction is very considerable over the bones, yet a depression, to the extent of about an inch, can be felt between the most projecting spinous processes; and the transverse processes stand so much out, that they press against the skin. He has perfect power in moving his lower extremities; and the sensibility of the skin is entire. He complains chiefly of the pain occasioned by several severe cuts



and bruises on the face, and is observed to move his legs up and down, expressive of suffering.

August 27th.—The progress of this case has been carefully watched, although the daily reports have not been kept. No symptoms of paralysis have appeared. On the second day, being fatigued with lying in one position, the patient turned himself round to the other side. He was cautioned against doing this; but was seen the next day turning round as before. The tumefaction has subsided; and the irregular projections of the vertebræ can be distinctly seen as well as felt. He has been purged, has taken salines and antimonials, and has had leeches repeatedly applied to the back, and cold lotions.

October 4th.—The patient remained free from symptoms of the spinal marrow being injured; and he left the hospital a fortnight ago. On visiting him at his house, I found him dressed, conversing with his neighbours. The position in which he was placed was remarkable. Instead of sitting, he stood by the side of a low table, and leaning forwards, with his body much bent, he kept his chest flat upon the table; thus resting the upper part of his body upon the table, to relieve the spine of the weight. This position, he said, was the easiest that he could find, except lying in bed. To show the way in which he walked, he began, before leaving the table, to prepare himself; and for this purpose, he grasped the front

part of both his thighs, a little above the knee, with his hands; and then, fixing his shoulders, and supporting his weight on his arms, with his knees bent, and taking short steps, he walked across the floor till he reached another table, where he proceeded to place himself as described above. On examining the spine, the bones were prominent as when he was in the hospital. He attempted to raise himself into the erect position, and he succeeded to a remarkable degree; but although the effort did not give him pain, the spine was so weak at the seat of the injury, that he quickly sank down again into the bent position.

August 11, 1830.—It is now two years since the patient met with the accident. I was therefore interested to learn what was his condition. I found his wife only at home, but she informed me that for a year and a half her husband has been in constant employment, in his former occupation, as a bricklayer. Although he lives in Paddington, he walks to Lincoln's-Inn-Fields, works during the day, and walks again home in the evening. His back is still flexible at the part where it was injured, and the bones project so much that the skin is occasionally fretted over them. He complains continually of the weakness and pain in his back, and is relieved by lying down.

Remarks.—The circumstance which gives the principal interest to this case is, that the patient had none of the symptoms indicating that the spinal marrow was injured. When we consider the complicated manner in which the vertebræ are locked into each other, and the powerful ligaments that bind them, and then estimate the force necessary to separate them, as in the above case, we cannot but be surprised that such a delicate organ as the spinal marrow, lodging within them, should escape injuries and retain its functions. The instances, however, are not uncommon, of accidents similar to that which I have related, where the seat of the injury was the same, being unattended with paralysis. I may refer to an interesting example of this kind, in Sir Charles Bell's "Surgical Observations," p. 140. The question thus arises—what is there peculiar in the anatomical structure at the lower part of the spine, which may explain the occasional occurrence of these favourable cases?

In the foregoing case, it was the last dorsal vertebra and first lumbar vertebra which were found displaced. In the other cases to which I have referred, the injury was at the same part, or only the distance of one vertebra higher up. Now it is at this part of the column that the spinal marrow begins to diminish in size, and to be surrounded by the leash of nerves that compose the *cauda equina*. When it reaches the second last dorsal vertebra, the spinal marrow, after forming a slight bulging, gradually decreases in its thickness, tapering and getting finer for some inches, until it terminates opposite the second lumbar vertebra. Hence, between these two points, it is enveloped in the numerous long and thick roots of nerves which it gives off close together, and which are destined for the supply of the lower extremities. These roots forming the cauda equina are, in point of firmness of texture, nearly the same as the common nerves distributed through the exposed parts of the body. It would appear that as the lumbar vertebræ not only sustain the greatest weight of all the spine, but enjoy considerable freedom of motion, and are, accordingly, liable to sudden and severe shocks, it was provided that the spinal marrow should cease thus high up, in order to save it from injury.

Whether this be correct or not, it is obvious that these loosely suspended roots of nerves, which occupy the lumbar region of the spine, cannot suffer in the same manner from the accidental twists or concussions of the bones at this part, as would the spinal marrow itself, if it had been so prolonged in its canal. It appears also, that where the spinal marrow is surrounded, at its termination, by these nervous cords, it must be defended by means of them, to a certain extent, from the effects of violence. Such may be the explanation why accidents, so severe in their nature as to rupture the ligaments, or even fracture the vertebræ across*, sometimes fail to produce immediate mechanical injury of the spinal marrow; and consequently if subsequent thickening of the membranes do not cause paralysis, the pa-

* See the case of Anton, in Sir Charles Bell's Surgical Observations, p. 138. The body of the eleventh dorsal vertebra was broken. There was no paralysis. The patient died from suppuration within the sheath of the spinal marrow. The spinal marrow itself did not appear to have suffered mechanically.

tient may remain powerful in his lower extremities, even when the spine is incapable, without artificial support, of sustaining the weight of his body.

REMARKS ON THE PATHOLOGY OF HYDROCEPHALUS.

With Illustrative Cases.

By Daniel Noble, Esq.
Of Manchester.

The present remarks relative to the pathology of hydrocephalus, refer, mainly, to the equivocal character of the symptoms commonly regarded as those of serous effusion within the head; and, to the frequent association of this event with inflammation of the lungs, in all probability as the immediate consequence of such inflammation.

If a reference be made to the works of any writer of the last century, or, indeed, to the generality of works of more modern date, it will be found that certain symptoms, such as stertorous breathing, fixity of the pupil, strabismus, and others of a like character, are regularly recorded as certain indications of some compression of the brain. And if depression of some portion of the cranium be not discovered, or if circumstances have not led to the conclusion that there exists some extravasation of blood, or some morbid growth, exerting such compression, the pathological inference deduced from the symptoms has always, until a recent period, been, that a serous effusion had taken place either into the ventricles, or between the membranes, of the brain. But of late years it has been most satisfactorily shewn, by the cultivation that has been bestowed upon morbid anatomy, that such symptoms as sensorial paralysis, fixity of the pupil, and stertorous breathing, may all, or each, exist, without the presence of any undue quantity of fluid within the head, or any other cause of cerebral compression; and also, that serum, pus, blood, or tumors, may all, or any of them, exist within the head, with a complete absence of those external signs. For abundant evidence upon these points, I need only refer to the works of Andral and Abercrombie, where these assertions are most fully borne out by the cases therein narrated. And, with these preliminary observations, I will now proceed to offer some remarks upon the pathology of hydrocephalus, more especially as it is observed in children; and then detail the particulars of two interesting cases of the disease, which I had the fullest opportunity of tracing from the onset to the termination, and which, in my own opinion, most completely corroborate the conclusions arrived at by modern investigators,—affording an exemplification of the association of hydrocephalus with pneumonia, as its probable consequence.

No doctrine in pathology can rest upon more satisfactory grounds, than that the train of symptoms, to which I have just alluded, afford no certain evidence of cerebral compression, but that they must be regarded as the result of certain conditions of the brain with whose nature we are but imperfectly acquainted; that, although these conditions most commonly precede, coincide with, or succeed to, the causes of compression, this last may nevertheless exist without their occurrence at all. Hence, in speaking of hydrocephalus, or serous effusion within the cavity of the cranium, we may, with strict propriety, assume the possibility of its existence, without the manifestation of its ordinarily associated symptoms. I think it right to reiterate this proposition, as, in practice, it is but too often disregarded. That the conditions of the brain originating the train of symptoms before alluded to, are nearly allied to those which give rise to serous effusion, there can be no doubt; and hence it is within the scope of my present design to refer to the various pathological states which the sure evidence of facts points out as furnishing the causes of this phenomenon. And, in the first place I may observe, that upon referring to the history of the doctrines taught upon this subject, we shall find the greatest contrariety of sentiment to exist. For example, many writers, amongst whom may be classed Goelis and most of his contemporaries, have considered hydrocephalus to be the result of inflammatory action in the brain, or its investments; whilst others, amongst whom Whytt seems to have occupied the most distinguished place, have gone to the opposite extreme, and have stated it to be associated with a diminution of vital energy, and the effusion to occur as the consequence of a laxity of the cerebral exhalants; and,

lastly, some have regarded the affection as specific in its nature, resembling inflammation in some respects, but differing from it essentially in others. But although this variety of sentiment as to the pathology of hydrocephalus may have existed, there will yet, I think, be no great difficulty in bringing all these opinions into an accordance with the facts, as they stand revealed to us by experience: for it is pretty evident that these various writers have not, in point of fact, been referring to the same disease. The source of error has mainly existed in their having regarded the serous effusion as the essence of the disease. And, as in those days the symptoms were almost universally regarded as constituting the disease, and the external signs of water in the head being considered to be uniform and unequivocal, no surprise need be felt that differences should have existed as to the true nature of the malady. But if, in accordance with the spirit of an improved and more philosophical pathology, we consider the hydrocephalus itself only as a symptom of antecedent changes—and if, moreover, we bear in mind that these antecedent changes vary in their characters, all having one of the symptoms in common, and that a serous effusion—I think we shall have a key to the elucidation of all the perplexity and contrariety that have arisen in discussions of this subject.

If we understand that the brain is subject to the same laws as every other structure in the animal economy—if we regard its investments as possessing no immunity from the susceptibilities of other membranous tissues—we shall be aware that their capillary exhalants may effuse their serum in undue proportion, under various morbid conditions. We shall know that a state of active inflammation, or a *sthenic* condition of the organization, may precede, and cause an aqueous effusion; that a diminution of energy, or an *asthenic* state, may lead to the same thing; and that some irregular action of the vessels, dependent altogether neither upon an increased nor upon a diminished energy, but on some *depraved* condition, may also occasion a like result. And as in these days we regard an appreciable change in function and organization as constituting the essence of disease, and as, in most instances, changes are so far appreciable as to enable us to discriminate between *sthenia*, *asthenia*, and *depravation*, and as these conditions differ most completely in their nature, so must cases of disease be estimated and regarded, according as the organization presents these various conditions; and not as any one symptom may happen to be absent or present.

It does not form a part of my present intention to detail in what possible manner an undue arterial excitement may lead to an exhalation of some of the serous constituents of the blood, nor how a diminution of the vascular energy, especially when combined with an undue serosity of this fluid, may bring about the same thing; nor yet how certain irregular states of the tissues may produce the result; for all these are matters of common observation. We all know, for example, how the peritoneum, in a state of active inflammation, will, in many instances, lead to an acute dropsy of the belly; under other circumstances, as after great exhaustion from uterine hæmorrhage, to a dropsy of a totally opposite character; and also, that frequently a strumous condition of the same tissue will induce an aqueous effusion within the sac. And similar phenomena ensue in like pathological states of other secreting textures, especially the membranous; and, under these circumstances, the nature and character of the disease is estimated, not according to the presence, or to the amount of the effusion, but according to the antecedent changes in the structure whence the fluid is derived.

Now it is quite clear that the membranes of the brain are subject to the same pathological changes as analogous structures in other parts of the system; and such being the case, it is obvious that the conditions to which the term "hydrocephalus" is applied, must be variable; and that consequently, the diagnosis, prognosis, and treatment, must vary according to the probable condition of structure preceding, and coincident with, the serous exhalation. And I would go farther, and assert with some confidence, that the question of mere presence or absence of effusion is a matter of but secondary importance. I know that in general the occurrence of this phenomenon is regarded as a most formidable event, and, in most cases, as the sure precursor of inevitable death; but I can only consider that such views have had their origin in the prevalent notion

that the presence of certain symptoms, to which I have before alluded, and which in a very large proportion of cases do certainly precede the fatal termination of cerebral disease;—I can but consider, I say, that these views have resulted from the prevalence of the idea that such symptoms and cerebral compression were necessarily coincident. But such opinions being unquestionably demonstrated to be fallacious, it follows that every inference that has been deduced from them must be equally so. It is true that in most cases in which we have effusion within the head, the danger to life is most imminent, but not, I contend, in consequence of the effusion, but of antecedent changes in the structure of the brain, or its membranes. I reiterate, that of the serous exhalation itself, we have no essential symptom manifested by irregularity of the functions; and I submit, that in every case our prognosis and therapeutical proceedings must be guided by the nature and extent of the cerebral disease with which it happens to be associated. The two cases the particulars of which I shall detail in the sequel, most fully corroborate the position which I have taken in the whole of these remarks; one presenting, in the highest degree, every external sign during life, commonly regarded as indicative of hydrocephalus, and yet the effusion being but inconsiderable; and the other, where the serum was most abundant, offering scarcely one of the symptoms formerly considered as the necessary consequence of hydrocephalus. These views are most fully propounded and illustrated by many modern writers, and hence it may be deemed a work of supererogation that I should submit them, in a new dress, to the members of this Society*; but believing, as I do, that they are often disregarded in practice, I do not think it useless that our attention should be specially directed to the subject—a result which may be expected to ensue from its deliberate discussion upon the present occasion.

Having thus far dwelt upon the pathological conditions associated with hydrocephalus, I will now proceed to the consideration of the second point, to which I referred at the outset of this paper—to the common occurrence of effusion within the head, as the consequence of pneumonia. That hydrocephalus is, in a great number of instances, immediately induced by the presence of pulmonary inflammation, especially in children, I am thoroughly convinced; and the conviction I believe to arise from an attentive observation of facts, capable of being combined, so as to accord with all our general notions of the laws of morbid process. In consulting any of the standard authors who have written upon hydrocephalus, we find very general allusion to its occurrence as an affection dependent upon some remote sympathy, as upon disorder of the liver, the mucous membrane of the alimentary canal, the mesenteric glands, or, indeed, of any of the abdominal viscera. Disease of the heart has also been enumerated as one of the exciting causes of cerebral affection. But, with the exception of a passage occurring in a tract on Measles, by the late Dr. Armstrong, casually alluding to the phenomenon, I have no where met with a recognition of the intimate relation which I believe to subsist between water in the head and inflammation of the lungs. My attention to this was first engaged by a clinical remark made by Dr. Whiting, physician to the Surrey Dispensary (whose practice, when a student in the metropolis, I was in the habit of attending), who, on one occasion observing an infant labouring under pneumonia, directed my attention to the turgid state of the veins of the head and neck, and stated his fears lest hydrocephalus should supervene; and, from that time to the present, I have never lost sight of the phenomenon afforded by the connexion; whose foundation, in fact, many cases, attentively observed, have, in my own mind, most satisfactorily established.

I do not mean to affirm that in every case where we have pneumonia we must expect hydrocephalus to supervene; but I do say, that if any predisposition exist, it becomes a matter of importance to attend to the best means of preventing such an occurrence. It may be asked, in what way I attempt to explain this association, in conformity with the known laws of pathology? And to this inquiry I will reply, by a brief exposition of the views that suggest themselves to me, in elucidation of the relation.

* The Manchester Medical Society—where the present paper was originally read.

It is a well-known fact, that whenever any obstruction exists to the due progress of the venous circulation, a tendency to serous effusion is induced in the radicles leading to the great trunks, where the obstruction exists. Thus sometimes we have œdema of the hands and wrists, from the glands in the axilla, in a state of enlargement, pressing upon the axillary vein. A like occurrence will also take place from undue pressure upon the femoral veins. A tuberculated or scirrhous condition of the liver, interrupting the freedom of the portal circulation, is a recognised cause of peritoneal dropsy. Now, in noting the phenomena dependent upon pneumonia, do we not discover what is precisely analogous? The blood which is sent into the lungs from the right ventricle does not circulate with its ordinary freedom: an obstruction to a greater or less extent almost always exists; and this obstruction must operate upon the whole current from behind, until we arrive at the venous radicles generally, and must influence, I apprehend, in an especial manner, the current in the veins by whose union the descending *cava* is formed. This obstruction in the pulmonary circulation, extending to the internal jugulars, and onwards to the sinuses of the brain, must tend, as a matter of course, to excite what is called venous congestion of that structure; and hence, if a predisposition to any morbid action in the brain exist, either of a *sthenic*, *asthenic*, or *depraved* character, it is highly probable that, under such circumstances, a serous effusion will take place. Indeed, this view, in connexion with the pathology of these affections, appears to me so obvious, that I can only feel surprise that it has not received more general attention.

As I have before stated, I have made many references, in expectation of meeting with a distinct recognition of the frequent association of pneumonia and hydrocephalus; but, with the exception above mentioned, I have no where seen particular notice taken of the former immediately leading to effusion within the head. On reading the chapter on hydrocephalus, in Underwood's popular work on the Diseases of Children, I find that, amongst the premonitory symptoms, "cough" and "difficult respiration" are enumerated, though he himself does not connect these phenomena with primary disease of the respiratory apparatus; but I feel little doubt that, had auscultation been practised at the time this author was an observer of disease, a crepitation would have been revealed upon application of the ear to the chest.

With regard to the character of the affection likely to be excited in the brain by the presence of pneumonia, it will, of course, depend upon the peculiar predisposition of the patient at the time. We all know that, in the great majority of instances, the brain is an organ which, in children, is at all times very much open to the influence of morbid agency; and hence, if a child be of a sanguine plethoric habit of body, with a vigorous circulation, we should expect that any cause, operating upon the brain in a way to produce disease, would excite an action of a *sthenic* character, and effusion might ensue as the probable consequence of the prolonged existence of this condition. If a child had been much exhausted by long-continued evacuations, with almost total destruction of the powers of digestion, and this had led, as a matter of course, to a diminution of the tone of the vessels, and to an undue serosity of the blood, special derangement of the cerebral circulation might be expected to induce effusion, the result of an *asthenic* condition of the brain. And the existence of a strumous diathesis, in connexion with pulmonary obstruction, would not improbably excite a *depraved* action, tending to hydrocephalus.

These various predisposing states of the system, and special conditions of the brain, might of course exist as the natural constitution of the patient; and in many cases, no doubt, as the result of modes of management. Neglect of depletion, in some instances of pulmonic inflammation, and the administration of stimulants, would evidently tend, if the foregoing views be correct, to arouse disease, of an active character, in the brain; and if the opposite course had been unduly pursued, the hydrocephalus of debility might be expected to ensue, and so on.

These remarks have their origin in attentive reading, and the careful observation of a fair proportion of cases; and as illustrating, most distinctly, the views that have been expressed in the whole of this paper, I will now proceed to detail the particulars of the two cases

of hydrocephalus supervening upon pneumonia, of which I have before spoken.

Mrs. Wilkinson's child, Newton-street, Ancoats, aged fourteen months, of plethoric habit, fair complexion, and of sanguine temperament, had been attacked with pneumonia, when about three months old, from which it had recovered under ordinary treatment. After this attack, the child improved gradually, both in health and appearance, and in every respect seemed likely to do well. When about six months old, a second invasion of the pulmonary affection occurred, from which a recovery again took place; but from this time the child's health was never completely re-established. Its bowels were disordered, with alternate relaxation and constipation; and there was rarely an immunity from nightly paroxysms of remittent fever. In the month of August, 1835, the child being a year old, diarrhœa and vomiting came on, accompanied with continued fever. The severity of these symptoms, however, in about ten days abated, but still disorder of the bowels existed more or less until the month of October, in the early part of which another attack of pneumonia occurred. This was opposed by small and frequently-repeated doses of calomel, salines, and the application of a few leeches to the chest; the warm-bath was also employed at the onset. Under this treatment the symptoms were alleviated, but after the lapse of a few days, owing to an astringent mixture being given by mistake, instead of a saline aperient, the bowels became locked up, and the febrile symptoms increased, with very great restlessness. On the substitution of the intended medicines, the symptoms again improved, when tartar emetic, in large doses, was administered, and the expectoration became abundant; after this the pneumonic symptoms almost entirely abated, but the child seemed reduced to the lowest pitch of inanition. Simple medicines, such as hydrarg. c. creta, were then given according to circumstances, and for a few days beef-tea and milk were taken with apparent relish, and a decided improvement took place; but the appetite failed, and slight paroxysms of fever occasionally occurred; there were, besides, general pallor, languor, drowsiness, and every visible indication of thorough exhaustion. At this time, fearing secondary affection of the brain, I directed cold applications to the head whenever the febrile paroxysms gave rise to increased temperature of the scalp. Besides the general symptoms of exhaustion, a harassing tenesmus existed for several days, which, however, yielded to starch injections. This state continued for about a week, when convulsions, of a slight character, came on from time to time; but these, though mild, were of long duration. Except when convulsed, the child continued perfectly sensible; the breathing was free and unembarrassed; there was no stertor, nor strabismus, nor immobility of the pupil; and according to the statement of the friends, it possessed perfect consciousness to the last, having spoken intelligibly, from its slender vocabulary, only half an hour before its death, which took place on the 28th October, 1835, as if from sheer exhaustion.

The day after its death a post-mortem inspection was obtained. From the appearances observed within the head, there can be no doubt that disease had been going on for some time. The dura mater was almost universally adherent to the calvarium. The arachnoid membrane presented the well-known milky aspect to a considerable extent; and the vessels of the pia mater were much engorged. The substance of the brain was of proper consistence, but its minute vessels were distinctly injected. A quantity of fluid, that must have amounted to many ounces, was found between the membranes and in the ventricles. This was not measured, but the quantity was certainly most unusual. That the serous effusion had only taken place just at the last, I cannot for a moment believe; I can but consider that in this instance it was the gradual result of the combined influence of diminution of vital energy, and of mechanical obstruction to the pulmonary circulation, — the former predisposing the brain to *asthenic* hyperæmia (in the language of Andral), and the latter acting as exciting cause of such condition, and the consequent effusion. The probability of the cerebral affection being, in this instance, of an *asthenic* character, was strengthened by the purple appearance of the blood contained in the arteries.

On opening the chest, pleuritic adhesions were very general, but there was

no effusion; congestion of the lungs was universal; hepatization of some parts had occurred, and in some places the consodidation seemed to be of no very recent formation.

The abdominal viscera, though indicative of long-continued derangement, presented no appearance worthy of especial note.

In this instance, then, we had successive invasions of pneumonia, which reduced the child to the lowest point of depression. All the symptoms arising in consequence seemed only of a character such as we generally observe after prolonged and gradually induced exhaustion. No external sign of special disease of the brain was present, nor any of the symptoms commonly set down as denoting effusion; and yet, on opening the head, it was found that most extensive changes had been induced, and, above all, that many ounces of serum had been poured out by the cerebral vessels.

The next case which I shall relate furnishes an instance of cerebral disease in connexion with pneumonia, occurring in a little girl of four years of age, whose family seemed to be predisposed to affections of the head; inasmuch as two or three of its members were remembered to have died of what was said to have been "water in the head." The patient was of sanguine nervous temperament, and of somewhat strumous diathesis. She was attacked with all the ordinary symptoms of pneumonia, about the middle of October, 1835. Leeches were applied to the chest, and the warm-bath was employed. After the bowels had been freely opened, calomel and salines were prescribed, in small and often-repeated doses; but, as I soon ascertained, the medicines were given very irregularly, and the symptoms increased: afterwards, the medicines were taken as directed, but no improvement occurred. The treatment was then changed, tartar emetic being administered; but no nausea, or excretion of mucus, was effected. In about ten days from the first invasion, I saw the girl labouring under every symptom denoting serious disease of the brain. Convulsions of a very severe character occurred from time to time; the breathing was rapid, laborious, and somewhat stertorous; the eyes were fixed and the pupils dilated, with insensibility to light, and the cornea presented the glazed appearance so often observed in such cases. The child died in a few hours after being seen by me in this state.

On removing the calvarium, the membranes of the brain presented every character of active inflammation; the vessels being engorged, and filamentous adhesions existing in numerous points between the two surfaces of the arachnoid. A small quantity of fluid had been effused, chiefly found in the lateral ventricles. The substance of the brain was somewhat softened, and very generally injected. The dura mater also adhered very strongly, in some places, to the inner aspect of the cranium.

On opening the chest, no pleuritic adhesions were discovered; but the lungs themselves, in some portions, evinced the signs of recent consolidation, and in others only congestion: some parts seemed quite free from the indications of previous disease. The minute ramifications of the bronchi were very generally obstructed by a thick tough mucus.

This case differs from the preceding in several very important particulars. In the first place there was, in this last, a very evident predisposition to cerebral disease; as evinced by the patient's own appearance and history, and by the fact of several members of the family having died of disease of the brain. Again: the pneumonic symptoms never abated, but their whole course was such as to induce very speedy obstruction to the pulmonary circulation, which appeared very distinctly to excite the affection of the head, which was accompanied, in a high degree, by the symptoms esteemed of old to be certainly diagnostic of serous effusion; and yet, on examining the interior of the head, the serum was found in no proportion to the severity of the symptoms; affording, in this respect, a striking contrast to the preceding case, in which the fluid must have existed to ten times the amount, with a complete absence of the equivocal symptoms.

I have related some of the particulars of the above cases, because they illustrate the position I have taken in these remarks more fully than any it has ever been my fortune to witness, and to note so carefully. They do not, however, by any means comprise the extent of the facts which I have observed, leading to similar inferences; especially as re-

gards the supervention of hydrocephalus upon pneumonia; and were not these remarks already extended sufficiently, I could still further illustrate the relation between affections of the brain and the lungs.

The practical deductions, however, which I would gather from all these considerations are, that, in all cases of thoracic disease in children, it is of the highest importance to keep a strict watch upon the state of the head; and that whenever, in such cases, any disturbance of its functions ensues, it should be met by treatment the most prompt; varying, of course, in its character, according to the particular circumstances of the case. Indeed, I would go farther, and assert, that even in the absence of any notable derangement of the head, it is highly proper, and indeed necessary, that it should receive the utmost attention in the first instance, inasmuch as we cannot be sure that serious lesions may not occur, and that, too, without the presence of any very striking symptom. It has become my own practice, in almost every case of infantile pneumonia, to direct at once that the cap be removed from the head, and that this latter be kept in an elevated position; and on the occurrence of any undue heat and dryness of the scalp, that sponging with cold vinegar and water be assiduously employed: and to these views, and to this practice, I have been led, not only from reading and clinical instruction, but also from the especial interest with which I have directed my own attention to cases of this description.

Manchester, Feb. 24, 1836.

CASE OF FATAL HÆMATEMESIS.

To the Editor of the Medical Gazette.

SIR,

As the following case appears to possess some interest for pathologists, perhaps you will give it a place in your valuable journal.—I remain, sir,

Your constant reader,

ROBERT HUNTER TEMPLE.

Islington, Feb. 26th, 1836.

William Carter, æt. 78, a pauper in the Islington workhouse, who was not under medical treatment, was taking down some articles from a shelf, when he was suddenly seized with vomiting of blood, which burst forth in large quantities from his nose and mouth. I attended in five minutes after the attack, but the man was dead. His nose, mouth, and face, were covered with blood, which was also spilt upon the floor, and about a quart was collected in a basin, into which he had vomited.

A post-mortem examination was made the next day, twenty-two hours after death, in the presence of my father and another medical gentleman, when the following appearances presented themselves. On opening the chest, the lung on the right side was found very large, and extended over to the left side. It was of a dark venous colour, and did not collapse on the removal of the sternum. On its anterior and inferior surface a dark blackish patch appeared, about the size of a hen's egg, an incision into which showed it to be composed of dark, bloody, congested matter; it was an effusion of blood into the cellular texture of the lung, not defined by any well-marked boundary, and resembling, except in the last-mentioned circumstance, the disease called by Laennec apoplexy of the lungs. Two other similar congestions were seen in other parts of the right lung. The left lung was extremely small, collapsed, almost impermeable to air, and strongly bound by adhesions to the costal surface of the pleura. The substance of this lung was soft and friable, and was torn in the endeavour to remove it from the chest. On cutting into this lung, the edges only were found permeable to air; the lower portions presented a firm, yellowish, semi-cartilaginous texture, while the upper and middle portions appeared broken down and extensively ulcerated; and the arteries were found crossing the ulcerated cavities, in the form of strong fibrous cords. No phthisical tubercles or ulcers were observed in any part, but the cavities appeared to be formed by the mere rotting of the pulmonary substance. On introducing the finger into the left pulmonary artery, the passage was found to be impervious, and on further examination, its canal was found to be closed up by the growth of a firm cartilaginous substance around its walls. This patient must have been attacked at some period of his life with pneumonia and pleuritis, terminating in hepatization and adhesions of the left

lung; and the case shows remarkably that nature can perform the function of respiration with only one lung, when the other is diseased and atrophied. The stoppage of the left pulmonary artery, which prevented the circulation of blood through the lung, was probably one of the consequences of the pneumonia. The heart was found somewhat large; the two auricles and the right ventricle were healthy, but the left ventricle was found dilated and hypertrophied, the dilatation being slight, but the hypertrophy considerable; the septum ventriculorum was very much thickened. The aortic semilunar valves were found hardened by a copious deposition of calcareous matter, but there seemed to be sufficient space for the passage of the blood. The aorta was degenerated along its whole course; patches of albuminous matter, in a hardened state, were thickly strewed along its course, and atheromatous deposits were situated below the lining membrane. This degeneration of the arterial coats is by no means rare, and is well known to occur in most old persons. The trachea was healthy, but on cutting into the œsophagus, a large quantity of blood was seen to issue from the wound.

The stomach was now examined. On a superficial view, it appeared large, and distinctly constricted in the middle. On partially opening it, we found it filled with a large quantity of dark, grumous, coagulated blood, mixed up with mucus and half-digested food: the constriction in the middle was of a size sufficient to admit a man's finger, and appeared formed by a constriction of the muscular coat, and a puckering of the mucous lining. The stomach, with a portion of the œsophagus and the pylorus, was now removed, laid completely open, and washed. The mucous membrane was rather soft, and was also red and injected; a layer of jelly-like, bloody, transparent coagulum, was removed from it with some little difficulty. The stomach being the organ whence the fatal hæmorrhage proceeded, it was examined with great care, but no lesion of its texture was in any part observable, nor was any vessel found ruptured, though the cœliac axis and its arteries were found degenerated in the same manner as the aorta. The liver was pale, and presented the appearance of what is called the *nutmeg liver;* and the spleen was small, soft, dark-coloured, and very friable. The cause of death in this case, therefore, was a spontaneous hæmorrhage from the minute vessels of the stomach, in such abundance as to impede the action of the nervous, circulating, and respiratory systems, and causing death by suffocation.

I do not presume to say that the case now related is an extremely rare one, but I do not remember to have seen or read of an instance, in which hæmatemesis was so rapidly fatal, and where there was no rupture of any considerable vessel to account for its occurrence.

PLAN OF RENDERING THE REGISTRATION OF DEATHS EFFICIENT FOR MEDICAL AND STATISTICAL PURPOSES.

To the Editor of the Medical Gazette.

SIR,

THE following rough notes were written on the spur of the moment, for the use of an M.P., when it was announced that the question of registration was coming before the House. Should you consider that the mode of registration I have recommended, and which is found highly serviceable abroad, would contribute to the enlightenment of medical practitioners, as men of science, and to their profit as men of business, you will perhaps have the kindness to publish my observations; they will probably give rise to the suggestion of improvements on the part of your readers.

I do not know the exact nature of the bill now being drawn; but the exclusion of the medical officer will be no less detrimental to the community at large than to the profession.

I remain, sir, in haste,

Your obedient servant,

HENRY BELINAYE.

17, George-Street, Hanover Square,
March 2, 1836.

I consider the registration of deaths as important in three points of view:— 1st, Regarding the insurance of life. 2d, As influencing the improvement of medical science and statistics. 3d, Relating to the criminal laws and police.

The first object mentioned, as contem-

plated in the registration I would recommend, is one that concerns particularly the *English* community, one more superadded to those uses for which it was designed on the continent, and to which it is found so well to respond.

Life insurance is by far the greatest improvement, and the noblest feature of civilization--that by which England surpasses all the olden communities, however great their civilization, as well as all contemporary nations. Setting aside all the commercial facilities it affords, it imparts to fathers of families a peace of mind which passeth all understanding of unmarried men. It improves and exalts the moral feeling of a nation, gives every man a stake in the well-being of the commonweal, and affords a pledge to the governing power of the state. There are no institutions, therefore, that statesmen, legislators, and philanthropists, should so much encourage as life assurances. Those that at present exist cannot meet the wants of society—cannot come within the scope of men of very small revenues, who are the persons to whom it is most important to afford their security. Those offices which demand the least premium enjoy no credit; the others exact premiums twice the amount necessary; and, although there is an equitable division of profits ultimately, the yearly payments are an absolute bar to married men of very limited revenue engaging in these assurances, particularly professional men, as there is no country in the world where appearances and external shew are so necessary to success in life. The proper registry of deaths, as I should wish it to exist, would compass the following, as well as many other objects:—Prevent life-assurance societies from being the losers by suicides, which have even been sometimes committed by persons to provide for their families—by murders, which last may also be effected by poison, and other means easily disguised, to obtain the sum the murdered individual has insured.

But these are the least important objects I contemplate. It would allow of establishing a new computation; a new and correct basis for life societies; enable these societies to reduce their premiums; to insure persons according to their age, and in relation to their being male or female, married or single, pregnant or not, diseased or not diseased, and according to the nature of their disease. That they should insure persons, although diseased, (within a certain morbid range) is of the highest importance; for if they do not, what numbers of persons they must exclude. How few individuals arrive at 25 years of age in our artificial state of society without the lesion or debility of some organ! Health is not a positive, but a comparative state of being: the difference betwixt the sanatory state of one man and another, is one of degree only. It is not rational to suppose that the wonderfully intricate and delicate mechanism of perishable man can be worked even for a few years without some slight impairment. Some person has had a watch for 10 years, without its ever having erred; to-day it stops, and the watch-maker, on inspecting it, finds that it can never go well again. So a man of health proverbially good, dies to-day of apoplexy, or of an accident, and his body being opened, his lungs or his liver are found to have been deeply diseased for many years. By the aforesaid mode of registry, people may assure themselves, according to their station and means of existence, their professions and avocations; and I need not say how absurd it is to make a calculation for assurance establishments based on the mortality of all classes taken together: the lowest classes, who do not insure, affording by far the greatest mortality.

I cannot see why charities, such as savings-banks, should not afford even the lower class means of life assurance. To give an idea of what importance the establishment of life insurance reaching the industrious classes, (of course the lowest it can scarcely touch) I will observe that in Paris an immense proportion of those classes die in the hospital; out of 261,360 persons who died in Paris from the year 1821 to 1830, 213,503, or 83 in 100, died in the hospital, leaving behind not even enough to bury them. Conceive the mental sufferings of those persons previous to death; their own position, and that in which they leave their families; think of the poverty, degradation, and prostitution of their sons, wives, and daughters! The mortality of children under age from this cause is known to be terribly extensive. I must, therefore, say once more, that if

by another mode of registration of deaths one could only compass the insurance of the majority of the persons now excluded, it would be an incalculable advantage to the moral and political structure of society. If one had to give an example of the triumphs of moral improvement in the Christian world, one would show, on the one hand in, the Chinese nation, with its boasted civilization, beginning in the remotest time, the parent ridding himself of the burthen of his children by murder; and on the other hand, the English father curtailing his dearly loved comforts to maintain his children even after his death. This at once gives a measure of the highest altitude of Christian civilization.

As regards the advancement of medical science, the mode in which these registrations have been hitherto managed has not only met these views, but all reasonings established upon them, either by foreign or native writers, have been altogether erroneous from their remarkable deficiencies and inaccuracies. It has been constantly the practice of parish clerks to omit for three or six months, even at the time of the cholera, sending in their returns, and then reporting them as belonging to the hebdomadal bills of mortality just elapsed. There can be nothing more extraordinary than the way in which these returns have been managed, except the still more surprising supineness and indifference of the great medical bodies to the subject, and this amidst the wants and difficulties inextricable which beset all men who wished to guide themselves and medical science, by reference to these reports. The conduct of governments and medical bodies on the Continent being different from ours "toto cœlo" in this respect, and their writers having consequently published on the basis of data thus obtained, works of the highest use and merit, which have been translated into the other contemporary languages, no reasoning is necessary to prove the use of these reports to the medical philosopher. Were they only a subject of an elevated scientific curiosity, they ought to be attended to; since it is known how constantly, one might add how infallibly, researches made for the gratification of the *hobbies* of philosophers have ultimately led to solid and important advantages. But there is no better means (setting aside all other important points of view) of studying and endeavouring to counteract *en grand* the diseases, and alleviating the sufferings, of the lower *strata* of the population, whose mortality is so enormous, when compared to that of the upper classes in England. By these reports, amongst other things, would be known the propriety of certain treatments in vogue, the prevalence of certain complaints, the use of certain prophylactics like vaccination, and the mortality of localities, which may be remedied by drainage; preventing the accumulation of overworked artisans in manufactories, of paupers in narrow streets and small tenements, &c. &c.; of delinquents in prisons and penitentiaries; of the sick in hospitals.

I will add but one observation more: that for twenty-three years that I have had my attention engaged in medical pursuits, there has never been a greater revolution, to my mind, in the constitution of disease; diseases having now changed their characters, and for the most part taken up chronic and insidious forms. As to the upper classes, if to their treatment be applied strictly the medical lore which is acquired in schools, fatal effects must ensue: for instance, that disease formerly so common—inflammation of the lungs, pure pneumonia—which, where it exists, requires abundant vascular depletion, is now comparatively rare in this sphere of life. For three years I have not seen, in London, a case in private practice where repeated copious bleeding had been employed, except where some young or unobservant medical practitioner, having bled largely the patient, and deprived thus the extremities of their irritability, the blood has congested upon the lungs, on the principle of "ubi stimulus, ibi fluxus." Here you must often bleed again, to withdraw the local congestion; and the patient, when he reaches the first step of convalescence, is reduced to the lowest ebb of life.

It is highly probable that the extraordinary diminution of certain diseases, particularly of the contagious, is attributable to their supervention of cholera, through whose instrumentality the depressed and diseased members of the community have been swept away; their abodes and haunts, which afforded a refuge and nidus for contagion, cleared out: contagion, like a thief, seldom har-

bouring but under rags, in filth and darkness, and almost always attacking first the weak and unarmed—the unprotected members of the community. This, however, in absence of good statistical reports, is mere probability, but if it were proved, would show once more that the exercise of Christian charity, and the application of "mèsures gouvernementales" to the hygiene of the lower classes, are the only means of security for all classes of society.

As regards criminal law and police, I must observe, that the mode of death, as well as the disease which caused it, cannot be known by such means as are at present adopted. The least important result of this is, that suicides are not brought to light. I have shown, under the previous point of view, the consequence. But I have not only heard (I could express myself more positively) of several instances of concealment of suicides, but I have also heard of cases of death, under the most suspicious circumstances, passed over without notice; one particularly of the most sinister complexion. Here the medical man could not act without taking upon himself the character of an informer, against the advice of his brethren and friends, and where, if he had put himself forward without the case proving one of murder or homicide, and his name had got into the papers, he would have been scouted by every body. Nor can it be expected that medical men will ever volunteer a demand for investigation under doubtful circumstances, as long as the law does not make it an unavoidable duty for them to do so.

Instead of the "*Officier Civil*," and the "*Médecin Vérificateur*," as on the continent, establishing the fact of the death of any member of the community, two old crones generally perform that office in England in each parish,—a trifling pecuniary compliment to them from the family of the deceased, and that of a glass of spirits, being the only result of their inspection. That these veteran ladies should be invested with an office of so much importance and gravity, proves that many of their *semblables* occupy higher offices. It shows an absence and want of feeling of propriety and of interest in the well-being of society,—an ignorance or a blindness inexcusable and inexplicable on the part of the governing power. There will always be an objection to legislation on this subject, on account of the natural repugnance of Englishmen to the invasion of their privacy by persons invested with any thing like an approach to an *inquisitorial* power. But setting aside the great advantages—nay, the necessity—of such an enactment as we wish to enforce, would it not be infinitely preferable that the office of visiting the houses of any deceased member of the community should be in the hands of educated and judicial persons, than in those of the persons previously described as at present so singularly trusted to? Is it not absurd that a coroner's inquest should be held upon persons who die of the most palpable causes, whilst doubtful cases escape investigation?

The following are an enactment and a mode of registration of death, having for their object—1st, the detection of suicide, of murder (particularly by poison and suffocation), infanticide, death after artificial abortion, &c.; 2dly, the improvement of the system of life assurance, and its protection; 3dly, the advancement of medical science, police, and statistics, and public health. This plan would likewise prevent persons being buried alive, as also the bodies of friendless and isolated paupers remaining uninterred until they have contaminated their neighbours.

> "No person to be buried without the inspecting medical officer (to be named for each district) being apprised of the circumstance, and having given permission,—which permission he is only to deliver after having called at the house of the deceased, with the clerk of the parish, visited the body, and in the presence of two witnesses, if possible, acquainted with the defunct, filled up and signed the following paper; which is likewise to be drawn up according to the same form by the medical man (if any) who has attended the deceased in the last illness. The medical superintendent to recommend a post-mortem examination of the body to be made by the medical attendants of the family. Information of death having occurred to be sent by the head of the family, within twenty-four hours after its occurrence, to the inspecting officer or clerk of the parish."

Name of the Deceased.	Date and Place of Birth, (if known.)	Sex.	Married or Single.	Year, Day, and Hour of Decease	Residence, in what District, Street and Number, and in what Story.	Nature and Duration of last Illness	Predisposing Causes.	Profession, Avocation, Habits.	OBSERVATIONS, in which the position and state of the Corpse, when discovered, may be recorded; besides the suggestions of Inspector.

TIC DOULOUREUX *A SYMPTOMATIC* DISEASE.

To the Editor of the Medical Gazette.

SIR,

IN your number for the 27th of February, there is a detailed report of a clinical lecture, by Sir Charles Bell, on tic douloureux, in which he exemplifies the useful agency of a medicine actively purgative in several cases, states his opinion that *tic* is a sympathetic pain, depending on distant and *visceral* irritation; and he claims a priority of right to this view of the disease, by the following expressions:—"It has appeared to me surprising that authors have omitted to found on the anatomy of the nerves, which leads so directly to the satisfactory explanation of the symptoms of this disease." p. 874.

Now I am far from wishing to diminish the claims of Sir Charles Bell to the esteem of the profession on account of his incessant and successful labours for the advancement of science; yet it may not be improper, nor, I trust, unreasonable in me to observe, that *the same view of the cause of tic douloureux has been placed on record sixteen years ago*, in a thesis printed at Edinburgh in 1820, by which my degree of M.D. was obtained at that University.

The thesis was not that of a young gentleman who must write about something at the close of his attendance on the classes, and is often indifferent on the choice of a subject; but it was a *practical essay*, the result of experience, accumulated in the treatment of a disease of rather unfrequent occurrence, during my practice in London as a surgeon-apothecary, or general practitioner, for twenty years; and contained, as I believe, a novel view of the causes of that complaint, by asserting,

Firstly, that I considered the pain of the face to be *symptomatic*—viz. that the morbid sensibility of the nerve was excited by irritation at a distance from the painful part.

Secondly, that the seat of irritation was in the *abdominal viscera*. Thirdly, by explaining the association between the nerves of the face and those of the viscera, and showing the direct line of communication, assigning as a reason why the division of the painful nerves failed in affording relief, *that the exciting cause was out of the reach of the knife*, as expressed in the following words:—

"Unde, procuddubio, intelligendum est, cur sensatio, pruritus, nimirum, dolor, irritatiove cujusvis generis, prout causa excitans sit, a visceribus ad faciem, cursu directo, volat; necnon docet, cur sectio nervorum minimè prodest ægrotantibus, si neuralgia facialis spasmodica symptomatica sit, junctio, enim, cum sympathetico magno profundior est, quam scalpellus chirurgi peritissimi pertingere queat."

The plan of treatment recommended was founded on two points. 1st. A perfect clearance of the alimentary canal. 2d. The employment of medicinal agents *afterwards*, which should bring the alimentary surface and the alvine secretions into a more healthy condition.

The tendency of the painful affection to periodical returns, without any cause sufficiently obvious, had not escaped my observation; and as cinchona, in powerful doses, had succeeded best in several cases with me, I preferred it, to fulfil

the *second* indication, but I have never employed it without discrimination, nor relied on it as *an antidote*, as may be collected from the following sentence, page 40:—"Actio curativa cinchonæ, febribus et hæmicraniis intermittentibus, ubique terrarum agnoscitur, et hujus effectus salutifer ægrotis, *neuralgiâ faciali spasmodicâ vexatis*, haud minus manifestabitur, si detur conditionibus *idoneis*, jam memoratis: *his, autem, prætermissis, aut malè ordinatis, minimè adjuvat.*"

In offering these remarks, I beg to be distinctly understood that, at present, I merely wish to notice the fact of identity of view with Sir Charles Bell; that I have, sixteen years ago, described tic douloureux as a *symptomatic* disease, caused by irritation in the abdomen, and endeavoured to point out the line of communication between the splanchnic nerves and those of the face, particularly the three branches of the fifth pair, and to vindicate my fair claim to priority. It is my intention to publish a treatise on this extraordinary and painful affection, taking for its basis the Thesis alluded to, and annexing the result of subsequent experience.

A copy of the Thesis was sent, in the autumn of 1820, to Sir Henry Halford, Bart., President of the Royal College of Physicians, and to each of the Censors, viz. Drs. Powell, Cooke, Macmichael, and P. M. Latham, and to many personal friends in the profession. A number of these were interleaved, bound in morocco and lettered, to form library books of reference, and not likely to be put aside like a loose pamphlet. A copy had been given to each of the medical students (more than 120) who graduated at Edinburgh in that year; it had been, therefore, widely diffused, and being an *original paper*, which had never been through the hands of any private tutor or grinder, the information conveyed was likely to be of more interest. It would seem, however, that Sir Charles Bell was not aware, or had forgotten, in 1836, that any writer on *tic douloureux* had noticed the association, and reasoned on the effects of a communication, between the nerves of the abdominal viscera and those of the face.

I have the honour to be, sir,
Your obedient servant,
ROBERT MASTERS KERRISON.

12, New Burlington-street,
March 1, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue à abréger."—D'ALEMBERT.

Flora Metropolitana; or, Botanical Rambles within Thirty Miles of London. With a List of the Land and Fresh-water Shells of the Environs of London. By DANIEL COOPER. 1 vol. 12mo. London, 1836.

WE are induced to bestow a passing notice on this little work, both because it is well calculated to supply a remarkable deficiency in the catalogue of books proper for the out-of-door studies of the metropolitan botanist, and because we regard with pleasure the appearance of a book which may be considered as the first fruits of the introduction of botanical science into the curriculum of medical education in London.

Being in some sort a catalogue, we cannot devote much space to it; but yet would wish to notice with commendation one feature in its construction. The environs of the metropolis are in it divided into districts, and an arranged list of the plants found in each of these, furnished for the guidance of those who may visit it; and under each locality the geological character of the spot is stated. We are glad, therefore, to see the recommendation of Dr. Daubeny, which he made a few years ago, in his "Specimen of a Proposed Index of the Oxfordshire Flora," adopted in the present case. Some have doubted, or denied, the connexion of the characters of the soil with the vegetation which clothes it; and although this is not the place to discuss the question of the correctness or unsoundness of the doctrine, we may be allowed to state that it is believed in, and advocated by the illustrious Haustmann, and made the subject of a treatise by Crome, of Hanover, from whose work we quote the following striking fact:—"When the proportion of clay in the soil of any place does not exceed 60 per cent., the *Trifolium arvense* may be found; but if the clay reach 80 per cent., you will search for it in vain."

We strongly recommend Mr. Cooper's book to the botanical students of the metropolis.

MEDICAL GAZETTE.

Saturday, March 12, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

CICERO.

MEDICAL CORONERS.

SOME persons are remarkable for the unlucky talent they have of always proving too much. When they have a point to carry, they overlay it with what they conceive to be argument, but which turns out to be only so much rubbish, wearying and disgusting those who give it any attention.

We often meet with examples of this sort; and by the way, the ingenious advocates of the skull-doctrines, calling themselves *phrenologists*, may be instanced as furnishing perhaps the purest specimen of the unhappy zeal we allude to: but we have been specially struck with the peculiarity in question, upon reading a pamphlet recently published, by Mr. Rogerson, of Liverpool*. In a brochure of about fifteen or twenty pages, he has so superabundantly proved the fitness of medical practitioners for the office of Coroner throughout the kingdom, that, if we had our doubts about it before, we are now strongly persuaded that the position is a false one. This we will show more fully presently.

Mr. Rogerson begins his address to the "Reform Corporations," by tendering to them, in the shape of copious extracts from the statute of Edward I., information respecting the nature of the Coroner's court. "This court," he sums up, "is, then, one of inquiry, and all its inquiries are for the purpose of deciding questions of *facts, not of law*." We shall here only stay for a moment to remind the author that the Coroner, in his capacity of judge, may have some *little* difficulties of law to disturb him occasionally—for instance, certain questions, which it is for him to decide, with respect to what is, and what is not, to be admitted as *evidence*; and the *law of evidence*, Mr. Rogerson must know, is not one of the simplest in our English jurisprudence.

The following passage shows the author's notions of what duties devolve on the Coroner, in his judicial capacity.

"A view of the external surface of the body merely will lead a practised eye to trace the hand of violence, or suspect some "foul deed." A more minute examination will explain if the death has been caused by the infliction of a wound, blow, or other injuries, either *from number, extent* (?), or on a part of the body essential to life. The fatal result will be equally exposed, if it has arisen from the natural operations of disease, or if it has been hastened by any rude act. This inquiry, primary and important as it really is, and as our laws have wisely made it, can be executed only by those who *intimately understand the laws of the animal economy*, and are profoundly acquainted with the numerous organs and functions of the human constitution,—with the different states in which they appear during health and disease, during life and death. Hitherto the inquiry is strictly *medical*, and the requisite information is afforded by anatomy, pathology, and surgery. By negligence, self-design, or guilt, destruction of life is frequently effected by drugs and poisons; of which the Coroner's inquiry can only be efficiently and justly prosecuted by discovering *the nature and properties of destructive substances, and their effects on living bodies*. This part of the inquiry is also strictly *medical*, and can only be attained by the aid of materia medica, chemistry, and toxicology. The various branches of a difficult, learned, and deeply interesting science, requiring years of labour and study fully to comprehend, are embraced in the elucidation of these questions, and are *absolutely necessary to forward the ends of justice*."

Mr. Rogerson evidently has a high opinion of the attainments of those medical men who are willing to become

---

* A Letter to the Reform Corporations, on the Necessity of Electing Medical Coroners. By George Rogerson, Surgeon, of Liverpool.

candidates for coronerships. But does he really mean to say that the medical *practitioner*, in the actual state of the profession in this country, is possessed of all this profound knowledge and extraordinary skill? or that, being so, the *judge* is himself to make the investigations which are at present usually instituted by the medical witnesses?

"The science of medicine," says Mr. R., "the various branches of which must be known to institute an efficient examination, has been cultivated and pursued exclusively by a distinct class of society, who alone are able to investigate and discover the *causes of death*, and to duly estimate all evidence bearing on them."

Surely the author here exaggerates not a little. That part of medical education, enabling the *practitioner* to make efficient examinations into the causes of death, is only of comparatively recent introduction into the schools: it is there even still little attended to, and but partially encouraged: and it is a special department of medical science—an application of all the branches—not attainable in ordinary practice, though, upon Mr. Rogerson's own showing, indispensable for the medical coroner. Either, then, the ordinary medical practitioner, of several years' standing, is ineligible to the coronership, or the only competent medical candidates are those who have lately come from the schools. This the author very clearly *proves*—though he certainly does not intend it.

We rather doubt that the question is fairly stated between the lawyer-coroner and the medical. "Is a lawyer," says Mr. R., "whose business *cramps* his mind, in the study and *perversion* of precedents, acts of parliament, judges' versions of them, and in *mechanically* copying forms of law, best qualified to preside in such a court? Decidedly not, will be the immediate answer." We admit the propriety of the answer, but deny that of the question: for it is what the lawyers call a *leading* question, and we, an uncandid one. An ignorant, prejudiced, dishonest coroner, every body must allow to be a nuisance which ought not to be tolerated for an instant. But must every person installed in the coroner's office necessarily be a man of this stamp, because he is not proficient in medicine?

Few readers, we imagine, will be satisfied with the authorities adduced by Mr. R. in support of his argument. They are, indeed, a remarkable trio—the late Mr. Hunt (of "matchless" notoriety), Mr. Joseph Hume, and Mr. T. Wakley; the first telling a very apocryphal story of an affair that happened while he was in Ilchester jail, and the last, quoted as a most *disinterested* witness, being a (rejected) candidate for a coronership, "on the expressed principle of that office being essentially medical!" Is it possible that the author could bring forward no *respectable* vouchers?

But to come to the gist of the matter, Mr. Rogerson says he has *proved* (no doubt to his own satisfaction) that the coroner ought to be a medical man, in order to appreciate the professional evidence given at inquests, and to explain it clearly and justly to the jury. But, with our author's leave, he might have gone a little further: on the same principle, and by virtue of several other *proofs* of the same kind stated *passim* in the pamphlet, he could readily shew that *the jury* ought also to be medical; nay, that judges and juries of all sorts, who hear and determine cases involving medical evidence, ought to be *bonâ fide* medical men: commissioners of lunacy decidedly should be so, and even the Lord Chancellor himself! Now this is what we call proving *too much*. We must, however, have done with Mr. Rogerson's production for the present.

The question may be put to us, whether we think coroners ought to be of

the medical profession? If by the profession be meant actual practitioners, we say decidedly not. But we will explain. The office of coroner, in order to be discharged in a manner suited to its great importance, ought to be filled by a man of sound judgment, strict impartiality, and very extensive acquirements. Those acquirements, should, unquestionably, embrace a large portion of medical and medico-legal knowledge; so large, indeed, as can scarcely be attained but through the medium of a regular medical education.

This, however, does not necessarily imply that he should be a *practitioner;* on the contrary, we hold that a person standing in such a relation to the public ought *not* to be entrusted with the duties of the office in question. It can be readily understood how the functions of the two avocations are incompatible. In most cases of emergency, where personal injuries likely to prove fatal have been received, medical men are the first called in, and become referees and witnesses of the circumstances that come under their observation. Are these the persons, thus mixed up in the transaction, who are afterwards to sit as judges concerning the matters of fact? Are they, who are themselves the chief witnesses, to sit in a judicial capacity in gathering the evidence, and then to direct the verdict of the jury?

It happens that this is no ideal case. Mark what has occurred within the last ten days. At Winchester, on Friday, the 4th instant, a criminal trial took place on a capital charge of child-murder. We shall not present the details here, as probably most of our readers have seen them reported in the newspapers; suffice it, that they were of a very remarkable and deeply interesting nature. But the fact to which we wish to call attention is this:—The surgeon who was called in, in the first instance, when the body of the infant supposed to be murdered was discovered, and who examined medico-legally both the accused mother and the dead child, *sat afterwards as coroner* in the case, and directed a verdict of WILFUL MURDER against the prisoner. Nor was this all. At the trial, which came on at the Assizes on the day above mentioned, who should come forward as principal witness for the prosecution, but the very identical surgeon, medical jurist, and medical coroner, who had already given his professional, and pronounced his *judicial*, opinion on the question!

Such an example as this,—and no doubt the same concurrence of accidents is by no means rare where there are medical coroners,—must prove, better than all Mr. Rogerson's arguments put together, that there is at least a *chance* of similar gross anomalies occurring wherever the same individual acts at once as a practitioner and a judicial functionary. We wish to be distinctly understood: our objection is not to the fact of coroners being men of medical education, but to their being simultaneously medical practitioners; for we hold that not only is medical practice *per se* incapable of qualifying a man efficiently to discharge the coroner's duties, but that it directly disqualifies, inasmuch as it is calculated both to distract and embroil him.

We do not think the law ever contemplated that the coroner and his jury should necessarily be very accomplished persons, or profoundly versed in the mysteries of science. It seems rather as if this court was instituted for plain inquiry, preparatory to further and more searching investigations; in which case, as it appears to us, the judge of the said court need not be a *very* learned or scientific personage, but rather one suited to act as a kind of middle man, or interpreter, between the homely understandings of the jury and the occasionally scientific testimony given by

professional witnesses. The technical explanations of the latter are to be conveyed to the dull ear of the uninitiated, through the medium of a person of good plain sense and general acquirements. This is what we conceive the legislature intended from the first, respecting the office of coroner. No doubt the progress of knowledge renders it desirable that the functionary should now be more largely gifted; and we have admitted the full propriety of this, in saying that he ought to be endowed with much medical and medico-legal knowledge.

In short, our opinion on the subject may be briefly summed up in this way:—Medical knowledge, in the present state of things, is of much importance to the coroner. But let no mere practitioner, therefore, fancy himself fitted to be a candidate; for in doing so, he will commit a great mistake. Ordinary medical practice is not sufficient to render a man competent to the investigations required of a medical witness. What, for instance, has the common routine of the physician or surgeon to do with the tests of live or still-births, in questions of infanticide? What has it to do with detecting the proofs of poison? It is plain, consequently, that even within the province of medical science, the practitioner has considerable acquirements to add. Nor let it be supposed, as is too often the case, that the knowledge of law required of the coroner is slight: we have already alluded to the law of evidence with which he ought to be familiar, and which is admitted on all hands to be a subject of no small intricacy; so it is with various other legal points belonging to his essential qualifications. The coroner, besides, it must not be forgotten, has several duties to perform in addition to holding inquests on dead bodies—duties, unquestionably, rather fitted for the lawyer than the medical man. We must, therefore, in conclusion, say, that medical men are certainly adapted to make excellent coroners—perhaps the best—provided, 1st, that they superadd to their ordinary practical attainments a competent knowledge of legal medicine; 2dly, that they make themselves perfectly qualified for the discharge of *all* the duties of the office, by being duly versed in the requisite law forms (for in this respect they will be closely and jealously watched); and 3dly, that they absolutely and unconditionally resign the practice of their profession. If they comply not with these provisions, we are persuaded that their meddling with the coronership at all will only be likely to bring disgrace on themselves and detriment to the community.

ROYAL MEDICAL AND CHIRURGICAL SOCIETY.

Tuesday, March 8, 1836.

H. Earle, Esq., F.R.S., President, in the Chair.

The Secretary, Mr. Partridge, commenced the business of the evening by reading over the minutes of the last meeting, the general annual one, held on the 1st March. We think the following facts, mentioned in the statement, worthy of being extensively known:—Unusual and large as has been the Society's expenditure for the past year (owing to the removal from Lincoln's-inn-fields, the new charter, the fittings-up of library, &c. in Berners-street) the resources of the Society have proved abundantly sufficient to meet its liabilities; so that at the present moment there is not a penny due. The admissions of new Fellows during the year have amounted to the unprecedented number of 35,—the largest number in any preceding year not having exceeded 10. It was announced that the President (Mr. Earle), and the other officers of the society, were re-elected.

The President rose to return thanks for the honour done him, and promised his utmost exertions to promote the interests of the society. He congratulated the

Fellows on the actual prosperity and the gratifying prospects of the institution.

Dr. CLENDINNING then resumed the reading of Dr. Kingston's paper,—introducing it by an abstract of that part which he had read at the last evening meeting. He also read a note received from the author, to announce his regret at being unable, through illness, to be present at the discussion this evening.

We give the following as an abstract of the whole:—

The paper was entitled, *Remarks on Two Forms of Atrophy of the Heart's Valves, which interfere with their function: founded on Cases.* By P. N. Kingston, M.D., Physician to the St. George's and St. James's Dispensary.

The first of these forms of atrophy, which has been hitherto altogether overlooked by pathologists, was defined "a simple shortening of the heart's mitral or tricuspid valve, without any diminution of its natural thinness, pliancy, and transparency; the orifice to which it belongs having at least the ordinary calibre." It has been observed by the author in numerous cases, in eight of which it had proceeded to a considerable extent, the length of the laminæ being in some cases only a quarter of an inch, and in one case the posterior lamina of the mitral valve being only the eighth of an inch at its greatest length.

The second of these (to which the aortic and pulmonary, as well as the auriculo-ventricular valves, are liable) is nearly allied to the preceding in nature and effects. "When so altered, the continuity of the valve is interrupted by apertures, sometimes of large size, and sometimes so numerous as to reduce the structure to a mere net work, while the remainder of the valve is in a state of attenuation, which is here and there often extreme, especially towards the edges of the apertures." In five of the cases a considerable portion of the valve had been thus affected. This cribriform condition of the valve, as connected with attenuation, Dr. Kingston had long believed to be also unnoticed by any author; but some time after the composition of his paper, he found a short passage in Laennec, which appears to refer to it.

Both the lesions, though not very rare, are of a nature easily to elude observation, until the attention has once been directed to them.

A valve, which has become shortened or cribriform, is of course incompetent to close completely the orifice to which it belongs; and hence permits that regurgitation which it was placed to prevent. The regurgitation, when dependent on shortening, will be liable to increase from bodily exertion; for it was shown by Mr. Hunter, that the heart at its diastole dilates much more when the body is in activity than when it is at rest; and it is evident that when an orifice has become unusually dilated at the diastole, its valves, if shortened, will at a succeeding systole be still less able to meet than they were before. Mental emotions, and other circumstances by which the heart's action is stimulated, will promote the operation of this lesion in the same way.

From this disablement of the valve arises a strong tendency to dilatation or hypertrophy of those parts of the heart posterior to the valve affected; to palpitation, venous congestions, anasarca, and effusion into the serous cavities; and where the mitral valve is defective, to dyspnœa and cough, to pulmonary congestion and inflammation, and to some of those symptoms which are apt to arise from deficient and irregular supply of arterial blood to the head and remote parts of the body.

These two species of atrophy sometimes co-exist, or are combined with other valvular lesions; and then, though each of the defects be slight, their influence thus united may be considerable.

A morbid "bruit" may, in some cases at least, be perceived by the stethoscope. Where the tricuspid valve is affected, there is distension, and sometimes pulsation, of the external jugular veins. Where the mitral valve is affected, the pulse is small and weak, in comparison with the heart's impulse; and it is apt to be irregular and unequal.

By a reference to these symptoms, and to the circumstances out of which the complaint arose, it may generally be ascertained whether or not there is valvular disease. The discrimination of these from the other valvular lesions is a point of great nicety, on which the author is not as yet fully prepared to speak.

These defects may now and then be congenital; but in all the present cases they could be proved to have occurred long subsequently to birth: a conclusion which coincides with Meckel's opinion respecting similar defects of the valves of the veins. They had evidently been produced by those species of absorption unattended with suppuration.

In the greater number of cases the valve affected had, from hypertrophy of the corresponding ventricle, over-exertion, &c., been subjected to an increased force of the blood's impulse; which, when from previous morbid affection the nutritive powers of the valves are weak, may exercise on them the same influence which unnatural pressure has been observed to exercise on all other organs and tissues of the body. To this combination of undue pressure and debility, the valvular atrophy was in these

cases referred. In the other cases there was reason to believe that the heart had been subject to gouty or rheumatic affection, which may have so impaired the nutrition of the valves, as to render them liable to be absorbed even under the pressure to which they are naturally subjected; in the same way that the cartilages of gouty and rheumatic joints are absorbed from the friction occasioned by the ordinary exercise of the limbs.

The author concluded by pointing out the errors which may have arisen from an oversight of these lesions; the practical advantage of detecting them during life, (even so far as to perceive that there is some valvular defect obstructing the circulation); the means by which the frequency and extent of the lesions may be diminished; and the circumstances under which it may be hoped either that the valvular structure may be restored to its original dimensions, or that the corresponding orifice and cavities may gradually diminish in calibre, so as to become adapted to the altered size of the valve.

There was no regular discussion of the topics of the paper; but some conversation took place on various anomalous conditions of the heart, principally functional.

Dr. Bostock exhibited to the Society some specimens of very remarkable urine, which he had recently procured from a man labouring under anasarca. The albumen abounded in such quantity as to render the fluid perfectly opaque. Some other urine voided by the same patient alternately with the albuminous kind was quite limpid, or almost wholly aqueous. It is understood that Dr. B. will draw up an account of this case.

Mr. Stafford, with the permission of the Society, introduced the man whose case (dislocation and fracture of the lower dorsal vertebræ) he described in the paper lately read, and of which we gave an ample abstract in our last number but one. With the exception of some stiffness in the back, and irregularity in the appearance of the processes of the vertebræ about the part injured, the recovery seemed to be complete. It will be recollected that the man fell, or jumped, backwards from the window of a first floor, cleared the area railings, and came upon his buttocks.

VARIETIES OF EAST INDIAN OPIUM.

It appears that the English market presents at least two varieties of opium brought from Turkey.

1. The first is what is proper Turkey opium, and the specimens which are regarded as best, instead of being compact, solid, and of dark brown colour, occur in masses about the size of the hand, soft, compressible, and elastic on the surface; not frangible, but sectile, and presenting on internal section a viscid compressible mass, pretty firm and dry at the external crust, though still receiving easily the impression of the nail, and soft, moist, and approaching to semifluid in the centre. The colour varies, being in the external drier parts between deep reddish brown and liver brown, and in the moister and softer portions lighter, between brownish red and chestnut brown, or something of the colour of the mineral grenatite, or between that and cinnamon stone. The smell is not unpleasant, and like that of the bean-husk. In a specimen which we lately examined, the exterior presented the seeds of a species of *Rumex*. Does this indicate that it belongs to the Smyrna variety, to be mentioned below?

It is remarkable, that notwithstanding the statements above noticed, in all the books and dispensatories on the characters of good Turkey opium, experienced druggists invariably prefer Turkey opium, which is soft, compressible, and moist, as now described. Its internal section is much intermixed with leaves, and it is even possible to recognize the petals of the white poppy. This contains about five per cent., sometimes six, of morphia. But the strength and purity of the very best Turkey opium vary so much, that for this no rule can be laid down.

2. The second variety of Turkey opium is that denominated Constantinople opium. This occurs in much smaller masses, being sometimes not larger than the hand of an infant of one year, and weighing from fourteen drachms or two ounces to three ounces and a half, or four; rarely more than that. The exterior of these masses, which are generally flattened and irregularly polyedral, is dry, hard, and of a broccoli brown colour, less perfectly covered with leaves, and showing smaller fragments of vegetable matter than the common Turkey opium. The masses externally are scarcely compressible, but they are not frangible but sectile; and the section is of a deep reddish, sometimes of chesnut brown colour, more uniform than that of the common Turkey opium, drier and firmer, and compressible, and receiving impressions only towards the centre. Some recent portions may be compressed externally, but they generally resume their figure. This opium is always procured from Constantinople, is believed to be reared with peculiar care in the country round the city, chiefly for the use of the

Turks themselves, is richer in morphia than the other species, and consequently brings in the market a higher price. It is occasionally impossible to procure it at any price.

3. It further appears, that in France is another variety of Turkey opium, known by the name of *Smyrna opium*, which is brought direct from that port, it is said, to Marseilles. This is in larger, rounder, and more irregular masses than the Constantinople opium; it has a black colour, especially internally, a stronger and ranker odour, and the cakes are covered with the seeds of *Rumex*, which M. Merat ascertained to be those of the *Rumex Patientia*. This opium is stronger than the common Turkey reddish opium, dissolves readily in water, and is used chiefly to manufacture morphia, which is said in it to be abundant.

The Egyptian opium occurs in small, flat, irregular masses, sometimes less than those of the Constantinople variety. It is always extremely hard, compact, either difficultly compressible or quite incompressible; and though it may be cut, it is rather frangible than sectile. Its fracture is conchoidal and resinous, its aspect shining, and its appearance uniform. It is equally hard at the circumference and centre, but receives the impression of the nail, leaving a lighter streak. It is remarkable, that though this variety agrees with the characters ascribed to the best Turkey opium, and Egyptian opium has been celebrated as the best in the European market by all writers, from Alston, Lewis, and Pomet, down to Dr. Duncan and Dr. A. T. Thomson, yet this is regarded by experienced druggists at the present time as much inferior to Turkey opium, and does not yield more than from 2 to 3 per cent. of morphia. It contains much caoutchouc and gluten.

It has been repeatedly stated by all travellers, from Chardin and Tavernier downwards, that the opium reared in Persia was of the best quality, and much superior even to Turkey opium; and while it is said that the genuine medicinal poppy is a native of Persia, and minute accounts of the effects of collecting opium on the persons engaged in it in that country have been given, it has been also said that all the best opium was brought from Persia. This may have been true about a century or 150 years ago. But at present we are assured by all experienced druggists, that either no opium is brought from that country, or what is brought is of inferior quality, or, in short, is not genuine Persian opium.

It appears, therefore, that the best kinds of opium in the English market are the two varieties of Turkey opium. But even these are so variable in qualities, that the most practised druggists assert that it is impossible to predict, from the external characters and appearance, the probable purity or productiveness of the article as a medicinal agent. It has been commonly supposed that the strength of Turkey opium is about double of that reputed to come from the East Indies; and it is stated by Dr. Anthony Todd Thomson to contain three times the quantity of morphia afforded by the latter.—*Dr. Smyttan, in Transactions of Medical Society, Calcutta.*

ON THE

FORMATION OF ÆTHER.

By Professor Mitscherlich.

The decomposition of alcohol into æther and water is not interesting merely by the production of æther, but is especially so as an example of a particular kind of decomposition, which cannot be so well followed with any other substance, and which is manifested in the formation of some important products; for example, in that of alcohol itself. M. Mitscherlich has endeavoured to elucidate the phenomena of this decomposition by the following experiments:—Take a mixture of 100 parts of sulphuric acid, 20 of water, and 50 of anhydrous alcohol, and heat it gradually until its boiling-point becomes 284° Fahrenheit. Alcohol is then allowed to fall gradually into the vessel which contains the mixture, and the current is to be so regulated that the heat of the mixture remains constantly at 284°. If, for example, the operation be conducted with a mixture of six ounces of sulphuric acid, one ounce and one fifth of water, and three of alcohol, and if the density of each two ounces of product as it is obtained be taken, it will be observed that this density passes gradually from 0·780 to 0·788 and 0·798, and afterwards remains constantly at the last-mentioned density, which is exactly that of the alcohol employed. If the operation be properly conducted, an unlimited quantity of alcohol may be converted into æther, provided that the sulphuric acid does not change. The distilled liquor is formed of two distinct fluids; the upper one is æther, containing a little water and alcohol; the lower one is water, with a little alcohol and æther. Its weight is nearly equal to that of the alcohol employed, and it is composed of

Æther	65
Alcohol	18
Water	17—100

If into six ounces of concentrated sulphuric acid six ounces of pure alcohol are suffered to flow gradually, a product of constant density is not obtained until the sulphuric acid has taken its proportion of water. Take, on the contrary, three ounces of sulphuric acid and two ounces of water, and let alcohol be added, drop by drop; the first two ounces distilled are merely spirit, if wine of specific gravity 0·926, containing scarcely a trace of æther. The density decreases until the quantity of water of the sulphuric acid is reduced to its proportion, and the product of the distillation has acquired the density of the alcohol.

If concentrated sulphuric acid be added to anhydrous alcohol in excess, pure alcohol distils at first; but when the temperature reaches nearly 260°, the first traces of æther begin to appear; the production of æther is at its maximum between 284° and 302°.

It results, from the preceding observations, that alcohol, when in contact with sulphuric acid, is converted into æther and water at a temperature of about 284°. A great number of analogous decompositions and combinations are known, which may be attributed entirely to the influence of the contact of bodies. The most remarkable example of this kind is that of the conversion of oxygenated water into water and oxygen, by the slightest trace of the peroxide of manganese and some other substances. The decomposition of sugar into alcohol and carbonic acid, the oxidizement of alcohol when it is changed into vinegar, are phenomena of the same kind; and so also is the conversion of starch and sugar by means of sulphuric acid. M. Mitscherlich, observing that in the preparation of carburetted hydrogen by means of sulphuric acid and alcohol, water is formed at the same time, attributes this decomposition of alcohol to the influence of mere contact, and not to the affinity of sulphuric acid for water.—*Journal de Phamacie, Juin* 1835.—*Phil. Mag.*

REPULSIVE POWER OF HEAT.

In the *Phil. Magazine* for the present month (March), Mr. H. F. Talbot, F.R.S. gives a short paper on this subject. The following experiments are worth extracting:—

Experiment 1.—*On the Vaporization of Sulphur.*

When a minute portion of sulphur is warmed between two plates of glass, it sublimes, and forms gray nebulous patches, which are very curious microscopic objects. Each cluster consists of thousands of transparent globules, exactly imitating in miniature the nebulæ which we see figured in treatises on astronomy. By observing those particles which are larger than the others, we find their figure not to be spherical, but plano-convex, with the flat side to the glass. Being very transparent, each of them acts the part of a little lens, and forms in its focus the image of a distant light, which can be perceived even in the smaller globules until it vanishes for minuteness. If they are examined again after a certain number of hours, the smaller globules are generally found to retain their transparency, while the larger ones are become opaque, in consequence of some internal change in the arrangement of their molecules. I find that Mitscherlich and others have noticed this property in sulphur of undergoing a spontaneous change. There is a circumstance attending this experiment which deserves particular attention. Although the sulphur has been sublimed by heating it over a lamp between two plates of glass almost in contact with one another, yet the globules are found adhering to the upper glass only; and as their number amounts generally to many thousands, it is evident that the preference which they thus exhibit to the upper glass must have some strong determining cause.

The reason of it is, no doubt, that the upper glass is a little cooler than the lower one; and by this means we see that the vapour of sulphur is very powerfully repelled by heated glass. The plano-convex form of the particles is owing to the force with which they endeavour to recede from the lower glass, and their consequent pressure against the surface of the upper one. I think this experiment is a satisfactory argument in favour of the repulsive power of heat, and I believe it has not been hitherto described.

Experiment 2.—*On the Vaporization of Arsenic.*

When a particle of arsenic is sublimed between two plates of glass, it forms nebulous patches, considerably resembling those formed by sulphur in the preceding experiment. But the microscope detects a great difference. Instead of a globular or semiglobular form, the particles of arsenic are crystallized. The minuteness of some of the crystals almost exceeds calculation. I would suggest the employment of this method to detect the presence of arsenic in minute quantities of matter. The difficulty of demonstrating its presence with sufficient certainty is shown by the number of chemical essays that have been written on the subject, while a particle of the size of a pin's head is amply sufficient to display this microscopic crystallization; and the form of the crystals

being distinct and definite, the observer can soon make himself acquainted with their figure, so as to run little risk of mistaking any other substance for them.

ON THE USE OF SETONS IN CHRONIC DISEASES OF THE CHEST.

M. Rostan recently directed the attention of his pupils to the case of a patient who had been admitted three years previously into the Hôtel Dieu. He was stated to have been affected with phthisis pulmonalis; and, as the case was deemed incurable, M. Rostan had recourse, as a last resort, to the introduction of a seton over the chest. Under the action of this remedy, the patient has now survived three years, and though not cured he has gained flesh, and is in other respects in a condition "*assez satisfaisant.*" M. Rostan proceeded to state, that he had been consulted by a physician, aged 35, (whose name and address he mentioned), who had suffered from cough for a month; his general appearance, however, was satisfactory, and no actual disease of any organ was made out; M. Rostan, therefore, only prescribed some simple remedies, and ventured to encourage him in believing that he would soon be well: some time afterwards the gentleman again returned, in a state of considerable anxiety; but still no very careful examination seems to have been made, and no active means to have been adopted. However, the patient returned yet a third time, and his aspect was now very sensibly changed,—he was now subjected to an attentive examination, and no doubt remained as to the existence of disease in the lungs. M. Rostan then recommended the introduction of a seton into the parietes of the chest. From this time the symptoms abated, and he improved so much as to be able to resume the practice of his profession, which he still continues.

Several other analogous instances were related by M. Rostan, which tend to confirm his opinion of the efficacy of the seton in chronic affections of the chest. The following case we give as rather a remarkable illustration:—

Madame —— was affected with disease of the lungs, which had proceeded so far that caverns were already formed in them. Being called into consultation, the Professor proposed the introduction of a seton, which, however, was violently opposed by the other attendant. "It would be inhuman," said he, "to have recourse to so painful a means, in a case which is so far advanced as to leave no hope." Nevertheless, the seton was used, and the patient rescued from certain death.—*Gaz. des Hôp.*

DIVISION OF THE TENDO-ACHILLIS,

FOR DEFORMITY.

A man, 46 years of age, was affected, from early life, with that kind of club-foot which compels the patient to walk on the toes. The deformity, however, was not congenital; it had come on at the age of six, in consequence of the bite of a dog in the heel. This obliged him to walk on his toes, and the gait, which at first was accidental, became habitual. The ankle-joint was entire; the foot of natural dimensions; the heel raised several inches from the ground. The remarkable success obtained in analogous cases, by M. Stromayer, in Hanover, and by M. Duval, in Paris, by means of dividing the tendo-achillis, and following this up by continued extension, determined M. Bouvier, under whose care the patient was, to perform the operation exactly in the manner of the Hanoverian surgeon. It is extremely simple as to its execution: a long narrow-pointed bistoury is thrust in behind the tendon and parallel to it, about six fingers' breadth above the external ankle. The blade of the instrument, as it were, grazes the posterior surface of the tendon, but the point is not pushed through the skin on the opposite side. A probe-pointed bistoury, as narrow as the other, and with a very convex cutting edge, is immediately introduced into the passage thus made, in such manner as completely to divide all the fibres of the tendo achillis. The operation being completed, the foot, in this case, admitted of being at once restored to its natural position. The wound healed by the first intention, and was cicatrized within a day or two. The foot was kept under the action of a very simple apparatus, by which it was kept always inclined towards flexion on the leg, keeping the heel down, and the toes in their proper place.—*Gazette des Hôpitaux.*

PHLORIDZIN.

Such is the name given to a substance which has recently been obtained from the bark of the apple-tree; more particularly from that of the root. It is said also to exist in the plum, pear, and cherry-trees. Phloridzin chrystallizes, is soluble in water, particularly at an elevated temperature;—soluble in concentrated acids, without decomposition, not solidifiable, and not containing azote as a constituent principle. It has been chiefly used in intermittents, in doses of from 10 to 15 grains. Various other particulars regarding it are detailed in the *Bulletin Méd. Belge.*

ALDERSGATE SCHOOL OF MEDICINE.

DR. CUMMIN.

The conduct of the *Lancet*, in assailing, and attempting to injure, the character of every gentleman supposed to be connected with this journal, is a proof at once of its black malignity, and of its hate and dread of ourselves. We have much pleasure in giving insertion to the following document (the best answer, in the present instance, to the *Lancet's* lies), volunteered to Dr. Cummin by his pupils and several other students belonging to the Aldersgate School. It was presented to him, with a suitable address, by Mr. Henry Landor, and a deputation of the students, on Friday, the 4th instant.

"Perceiving a statement in the *Lancet* of last week, to the effect that it was the intention of Dr. Cummin to resign his connexion with the Aldersgate School, 'in consequence of the exasperated feelings of the students;' we, the undersigned, pupils of that school, come forward to state that no such feeling exists amongst us: on the contrary, we hope that as Dr. Cummin possesses the esteem of all of us, we shall long have the pleasure of meeting him as a lecturer in our theatre."

Fifty-five signatures are attached; and we are informed that the number would have been doubled, had it been generally known that the document was in preparation. We regret we have not room for the names at full length.

THE METROPOLITAN UNIVERSITY.

Several gentlemen have been mentioned as likely to receive appointments either as Commissioners or Examiners in the new University. We refrain, however, from giving them at present, because we believe that none have as yet been actually nominated, and because we feel assured that some of those with whose names rumour has been busy never will be so. By the way, it is scarcely fair, we think, to drag any one before the public in a manner which necessarily becomes rather awkward, if the honour, prematurely announced, be not eventually conferred.

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XXV.

I PROCEED in this lecture to examine—

NITRIC ACID.

History and synonymes.—This acid was known to Geber in the seventh century. The nature of its constituents was shewn by Cavendish, in 1785, and their proportion afterwards determined by Davy, Gay-Lussac, and Thomson. It has been known by various names, such as *Glauber's spirit of nitre, aqua fortis,* &c.

Native state.—It is never found in nature pure. Combined with potash, soda, lime, and magnesia, it is met with on the surface of the earth in various parts of the world. Traces of it have been detected in rain-water, after thunder-storms. It is found in some vegetables; for example, *borage,* the *nettle,* the *sunflower,* and *pellitory of the wall,* in *cissampe'os pareira,* &c.

Preparation.—In the London Pharmacopœia, equal weights of protohydrate of sulphuric acid and nitrate of potash are ordered to be distilled in a glass vessel. These proportions are about equal to two atoms of the protohydrate, and one of the nitrate.

The *theory* of the process is the following:—The potash of the nitrate uniting with the real acid of the protohydrate, forms bisulphate of potash; the nitric acid of the nitrate, with $1\frac{1}{2}$ atoms of water of the protohydrate, forms 1 atom of liquid nitric acid which distils over, while half an atom of water remains in combination with the bisulphate. In the following formula I have doubled the number of atoms, to obviate the difficulty of employing half atoms.

Reagents.	Results.
$2\ \dot{K}\ \overset{\therefore\therefore}{N}$	$2\ \overset{\therefore\therefore}{N} + 3\ \dot{H}$
$4\ (\dddot{S} + \dot{H})$.	$2(\dot{K} + 2\ \dddot{S}) + \dot{H}$

The residual salt, when crystallized, constitutes the *supersulphate of potash* of the Pharmacopœia, or *sal enixum* of the shops. Manufacturers seldom use glass vessels, but an iron or earthen pot, with an earthen head; the latter is connected with large earthen two-necked bottles. The acid, when pure, ought to be colourless, but it is generally more or less coloured; for in the first part of the process, the excess of sulphuric acid deprives the nitric acid of its water, and in consequence of this the latter is decomposed into nitrous acid and oxygen: so also, in the latter part of the process, nitrous acid is again generated from the preponderance of the sulphuric acid. Diluting the sulphuric acid with water will counteract the formation of this nitrous acid, by saturating the affinity of the sulphuric acid for water.

Properties. — When pure, it is colourless; but owing to the presence of nitrous acid, is sometimes yellowish, brownish, or even greenish. In this state it constitutes the *nitrous acid* of the shops. We may readily generate this compound by passing the binoxide of nitrogen into colourless nitric acid: the latter is partially deoxidated and converted into nitrous acid: the binoxide also becomes nitrous acid by oxidation. This coloured acid may be rendered colourless by gently heating it, to drive off the nitrous acid. It fumes in the air, owing to its affinity for water: by exposure to solar light, it is partially decomposed into nitrous acid and

oxygen, and becomes coloured. By the action of combustibles (as charcoal, phosphorus, sulphur, and some of the metals) it is decomposed, with the evolution of binoxide of nitrogen; and by the action of the hydracids it is also decomposed.

Characteristic tests.—This acid is best recognized by the following tests:—(*a.*) Drop into it a piece of copper (as wire or foil); effervescence takes place, owing to the escape of the binoxide of nitrogen, which becomes brown in the air, by the formation of nitrous acid gas, while a greenish blue solution of the nitrate of copper is formed. (*b.*) A little morphia, brucia, or strychnia, dropped into the acid, renders it red; and this colour is deepened by supersaturating with ammonia. (*c.*) If a little pure hydrochloric acid be added, the compound has the power of dissolving leaf gold. (*d.*) Boiled with sulphate of indigo, it destroys the colour of the latter. (*e.*) Lastly, saturated with an alkali (as potash), the resulting salt has the power of deflagrating, when thrown on a red-hot cinder, or charcoal.

Composition.—Pure or anhydrous nitric acid is composed of

1 atom of nitrogen	= 14
5 atoms of oxygen (8×5)	= 40
	54

In the liquid form, however, it is always combined with water, and the strength of it in this state is determinable either by taking its specific gravity, or by observing its saturating power. The acid prepared according to the Pharmacopœia has a specific gravity of 1·500; and Mr. Phillips thinks it is the strongest procurable, though several chemists assert they have obtained a denser acid. When of this gravity, nitric acid is said by Mr. Phillips to be thus composed:—

Anhydrous nitric acid	75	...or 1 atom	54
Water	25	..or 2 atoms .... (9×2)	18
	100	or 1 atom of bi-hydrate of nitric acid	72

However, the experiments both of Dr. Ure and of Dr. Thomson seem to show that acid of this specific gravity does not contain so much water. Dr. Ure states that it consists of

Anhydrous nitric acid..79·7	which would give	1 atom of anhydrous acid..	54
Water................20·3	very nearly	$1\frac{1}{2}$ atom of water $(9\times1\frac{1}{2})$	13·5
		or 1 atom of sesqui-hydrate of nitric acid	67·5

so that on the latter supposition the strong liquid acid is a *sesqui-hydrate.*

Impurities.—A little nitrous acid is the only impurity likely to be present, and which is of no practical importance. Sulphuric acid may be detected by a barytic salt, and muriatic acid by nitrate of silver. Always dilute the acid before testing for the impurities.

Physiological effects.—(*a.*) In the *concentrated* form the acid acts as a powerfully corrosive poison, which property it derives in part from its affinity for water, but more especially from the facility with which it gives out oxygen; so that the appearances caused by its action on some of the tissues are different from those produced by sulphuric acid. Thus the permanent yellow stain which it communicates to the cuticle is peculiar to it. Iodine, indeed, stains the skin yellow or brown, but a little caustic potash readily removes the colour, whereas the yellow stain produced by nitric acid becomes orange on the addition of an alkali or soap. Bromine also stains the skin yellow, but when recently produced, the colour may be removed by potash. In Dr. Roupell's work on Poisons is a drawing representing the tongue, pharynx, &c., of a boy poisoned by this acid; and it will be observed that in those parts where the cuticle is left adherent, it has acquired a citron colour. The same kind of blackening is frequently noticed in the stomach as when the sulphuric acid has been swallowed. The *symptoms* caused by the ingestion of this acid in the concentrated state are analogous to those described in the last lecture when speaking of sulphuric acid. The yellow, citron, or orange spots, sometimes observed on the lips, chin, or heads, will, when present, at once indicate the kind of acid swallowed. Sometimes the binoxide of nitrogen is evolved by the mouth.

(*b.*) Properly *diluted*, it produces effects similar to those caused by the dilute sulphuric acid already described. It is said, however, to act less evidently as a tonic, and to be more apt to disagree with the stomach, so that it cannot be employed for so long a period. In some cases it has excited ptyalism, and from this circumstance, as well as from the occasional benefit derived from its use in the venereal disease, it has by some writers been compared, in its operation, to mercury, a com-

parison founded rather on theoretical than practical considerations.

Use.—(*a.*) *Externally*—it is employed both in a concentrated and diluted form. In *sloughing phagædena* the *strong acid* is applied as recommended by Mr. Welbank, with the best effects, as I have on several occasions witnessed. The best mode of using it is by a piece of lint tied round a small stick or skewer. When the slough is very thick, it is sometimes necessary to remove part of it with a pair of scissors, in order to enable the acid to come in contact with the living surface. *Largely diluted*, (as 50 or 60 drops of the strong acid to a pint or quart of water) it is a favourite application of Sir Astley Cooper to sloughing and other ill-conditioned sores. In the form of *ointment* (the *pommade d'Alyon*, or *oxygenated ointment*), it has been used in various skin diseases, more particularly porrigo and the itch.

(*b*) *Internally*—this acid has been very extensively employed in *venereal diseases*, but with variable success. That it has been, and is frequently serviceable, no one can doubt who reads the immense body of evidence offered in its favour by Scott, Kellie, Albers, Prioleau, Rollo, Cruikshanks, Beddoes, Ferriar, and others. But on the other hand it is equally certain that on many occasions it has been useless. The same remark, indeed, may be made of mercury, or of any other remedy, but the frequency of beneficial influence of this acid, will not bear a moment's comparison with that of mercury. However, we frequently meet with syphilitic cases in which the employment of this mineral is not admissible, or is useless. Thus it will be found that mercury can rarely be employed with advantage in scrofulous subjects, or in persons whose idiosyncracies render them peculiarly susceptible to the influence of this metal: again, in sloughing sores, it would be inadmissible. Now these are the cases in which we employ nitric acid with benefit; and I believe the best mode of administering it is in conjunction with the compound decoction of sarsaparilla. Under the head of "nitric acid," in Mr. Samuel Cooper's *Dictionary of Practical Surgery*, you will find a good historical account of the uses of this acid in the venereal disease.

In *skin diseases* (especially in impetigo and pityriasis) it is spoken favourably of by Rayer, given to the extent of half a drachm daily in barley-water. In *lithiasis* it has been used in the same cases as the sulphuric acid. As a *disinfectant* it has sometimes been employed in the form of vapour, which is obtained by adding strong sulphuric acid to powdered nitrate of potash, and applying heat.

Administration.—For facilitating its employment, a dilute acid (*acidum nitricum dilutum*) is kept in the Pharmacopœia. It is prepared by mixing one fluid ounce of the strong acid with nine fluid ounces of water. This liquid has a specific gravity of 1·080. It is given in doses of from 10 to 50 or 60 minims.

I have already alluded to an *ointment of nitric acid.* It is prepared in imitation of Alyon's ointment, and hence it is frequently termed *pommade d'Alyon.* In the Dublin Pharmacopœia is a formula for it. It is there prepared by adding $5\frac{1}{2}$ fluid drachms of nitric acid to a mixture of 1℔. olive oil, and 4 ounces of lard. Binoxide of nitrogen gas is evolved, showing that the fatty matter receives oxygen (hence the compound is called *oxygenized fat*). This preparation has a firm consistence, and a yellow colour. It has been employed in various cutaneous diseases. It is said to be more efficacious when recently prepared.

Antidotes. — Poisoning by nitric acid requires precisely the same treatment as that already described for sulphuric acid.

HYDROCHLORIC ACID.

History and synonymes.—Liquid hydrochloric acid was probably known to Geber. Glauber, however, first procured it by the process now usually followed, and hence its name, *Glauber's spirit of sea salt.* It has also been called *marine acid*, and usually *muriatic acid.* Scheele, in 1774, may be regarded as the first person who entertained correct notions of its nature, and we are indebted to Davy for establishing the fact that this acid is composed of hydrogen and chlorine.

Native state.—It is found in both the organized and the inorganized kingdoms. Thus it is one of the products of volcanoes, and is found in the neighbourhood of Mount Ætna, Vesuvius, &c., in a gaseous state. It seems to be an essential constituent of the gastric juice, and hence, probably, one of the uses of common salt as an article of food, is to furnish this acid.

Gaseous Hydrochloric Acid.

Preparation.—It is obtained by the action of strong liquid sulphuric acid (*protohydrate of sulphuric acid*) on dried common salt, (*chloride of sodium*) contained in a tubulated retort, the gas being collected over mercury; or it may be generated in an oil flask and collected in bottles, by means of a tube curved twice at right angles. The *theory* of the process is this:—The water of the hydrated sulphuric acid is decomposed into its elements, hydrogen and oxygen, the latter of which unites with the sodium of the salt to furnish soda, with which the sulphuric acid combines to form sul-

phate of soda; while the hydrogen of the water, with the chlorine of the salt, forms hydrochloric acid gas.

Reagents.	Results.
Na Chl	H Chl
$\dddot{S}\ \dot{H}$	$\dot{Na}\ \dddot{S}$

Properties.—It is a colourless invisible gas, fuming in the air, in consequence of its affinity for aqueous vapour. It is rapidly absorbed by water. Its specific gravity is, according to Dr. Thomson, 1·2847. It has a pungent odour and acid taste. Under strong pressure (40 atmospheres) it becomes liquid. It is neither combustible nor a supporter of combustion. When added to a base, (that is, a metallic oxide), water and a chloride are the results.

Characteristic tests.—Its fuming in the air, its odour, its reddening moistened litmus paper, and forming white fumes with the vapour of ammonia, are part of the means by which it may be recognized. Dissolved in water, it may be detected by nitrate of silver, as I shall presently mention, in speaking of the liquid acid.

Composition.—It is composed of—

1 atom of chlorine . . .	36
1 atom of hydrogen . . .	1
	37

Or by measure of equal volumes of its constituents, which combine without condensation.

Constituents.	Results.
Chlor. =36	Hydrochloric acid gas =37
Hydr. =1	

This composition is determinable both by synthetic and analytic means. Thus hydrogen and chlorine may be made to combine by light, heat, or electricity, and the result of the combination is hydrochloric acid. On the other hand, we can decompose this gas by electricity, or by various reagents, as the metals.

Physiological effects. — (*a.*) *On vegetables.* Mixed with 20,000 times its volume of atmospheric air, this gas is said by Drs. Christison and Turner to have proved fatal to plants, shrivelling and killing all the leaves in twenty-four hours. But in the 10th volume of the MEDICAL GAZETTE you will find some experiments, detailed by Messrs. Rogerson, from which it would appear that this gas is not injurious to vegetables when mixed with 1500 times its volume of air. Dr. Christison ascribes these different results to Messrs. Rogerson having employed glass jars of too small size. We have good evidence of the poisonous operation of this gas on vegetables in the neighbourhood of those chemical manufactories in which subcarbonate of soda is procured from common salt. The fumes of the acid which issue from these works have proved so destructive to the surrounding vegetation, that in some instances the proprietors have subjected themselves to actions at law, and have been compelled either to pay damages, or to purchase the land in their immediate neighbourhood.

(*b.*) *On animals* this gas acts injuriously, even when mixed with 1500 times its volume of atmospheric air. Mice or birds introduced into the pure gas struggle, gasp, and die, within two or three minutes. Diluted with atmospheric air, the effects are of course milder, and in a ratio to the quantity of air present. In horses it excites cough and difficulty of breathing. When animals are confined in the dilute gas, in addition to the laborious and quickened respiration, convulsions occur before death. Messrs. Rogerson state, that "In a legal suit for a general nuisance, tried at the Kirkdale Sessions-house, Liverpool, it was proved that horses, cattle, and men, in passing an alkali-works, were made, by inhaling this gas, to cough, and to have their breathing much affected. In the case of Whitehouse *v.* Stevenson, for a special nuisance, lately tried at the Staffordshire assizes, it was proved that the muriatic acid gas from a soap manufactory destroyed vegetation, and that passengers were seized with a violent sneezing, coughing, and occasional vomiting. One witness stated, that when he was driving a plough, and saw the fog, he was obliged to let the horses loose, when they would gallop away till they got clear of it." It acts as an irritant on all the mucous membranes.

(*c.*) *On man* this gas acts as an irritant poison, causing difficult respiration, cough, and sense of suffocation. In Mr. Rogerson's case, it caused also swelling and inflammation of the throat. Both in man and animals it has appeared to produce sleep.

The action of hydrochloric acid gas on the lungs of animals is injurious in at least two ways: by excluding atmospheric air, it prevents the decarbonization of the blood; and, secondly, by its irritant, and perhaps also by its chemical properties, it alters the physical condition of the bronchial membrane. The first effect of attempting to inspire the pure gas seems to be a spasmodic closure of the glottis. Ap-

plied to the conjunctiva, it causes irritation and opacity.

Use.—It has been employed as a *disinfectant*, but it is admitted on all hands to be much inferior in this respect to chlorine. The Messrs. Rogerson go so far as to deny that it possesses any disinfecting properties at all. It is perhaps equally difficult to prove or disprove its powers in this respect. The experiments of Guyton-Morveau, in purifying the cathedral of Dijon, in 1773, are usually referred to in proof of its disinfecting property. I would recommend you always to prefer chlorine, or the chlorides of lime or soda; but if you are so placed that you cannot obtain these, why then you may resort to this acid. In neutralizing the vapour of ammonia it is certainly powerful.

Application. — In order to fumigate a room, building, or vessel, with this gas, pour some strong sulphuric acid over dried common salt, placed in a glass capsule or iron pot, heated by a charcoal fire.

Antidote.—Inhalations of the vapour of ammonia may be employed to neutralize those of hydrochloric acid gas. Symptoms of bronchial inflammation are of course to be treated in the usual way.

Liquid Hydrochloric Acid.

Preparation.—In the Pharmacopœia, this is ordered to be prepared by distilling in a glass retort 2 pounds of dried common salt, 20 ounces by weight of sulphuric acid, and 1½ pints of water.

Manufacturers, however, do not follow this process. They usually employ an iron vessel, and put the water into the receiver instead of mixing it with the sulphuric acid. In a large manufactory near London, an iron cylinder, placed horizontally over a fire, is used for the retort. The salt is put in at one end, which is then closed up by a round iron plate, perforated to allow the introduction of the leg of a leaden funnel, through which the sulphuric acid is added. The muriatic acid gas is conveyed by a pipe into a double-necked stoneware bottle, half filled with water, and connected with a row of similar bottles. The *theory* of the process is the same as that for procuring the gas.

Properties.—When pure, the liquid acid is colourless, fumes in the air, and possesses the usual characteristics of an acid. It has the odour and taste of the gaseous acid. Its specific gravity varies with its strength. It is decomposed by some of the metals (as zinc and iron), hydrogen gas being evolved, while a chloride is formed in solution. It is decomposed by those oxyacids which contain five atoms of oxygen—namely, nitric, chloric, iodic, and bromic acids: the oxygen of these acids unites with the hydrogen of the hydrochloric acid to form water.

Characteristic tests. — (*a.*) A solution of nitrate of silver causes a white precipitate in dilute hydrochloric acid. This precipitate is the chloride of silver, and is recognized to be such by the following properties:—it is soluble in a solution of ammonia, but is insoluble in nitric acid, whether cold or hot; secondly, it readily blackens when exposed to the solar rays; and, lastly, it fuses at about 500° F., and forms a horn-like mass: hence its name, *Luna cornea.* The facility with which the chloride dissolves in ammonia, distinguishes it from the bromide and iodide: its insolubility in nitric acid distinguishes it from carbonate, oxalate, and cyanuret of silver. (*b.*) The addition of a few drops of nitric acid to the hydrochloric acid, enables it to dissolve leaf gold. (*c.*) Liquid muriatic acid produces white fumes when brought near ammoniacal vapour.

Strength.—The strength of the solution is determined by observing its specific gravity, or by examining its saturating power. Prepared according to the College formula, its specific gravity is 1·160; and according to Mr. Phillips, it consists of—

Hydrochloric acid gas .	32·4
Water	67·6
	100·0

By reference to Dr. Thomson's table, you will observe that acid having the above-mentioned gravity may be regarded as consisting very nearly of—

1 atom real hydrochloric acid	37
8 atoms water (9 × 8) . . .	72
1 at. octohydr. of hydrochlor. acid	109

Atoms Acid.	Atoms Water.	Acid in 100 of Liquid.	Specific Gravity.
1	6	40·659	1·203
1	7	37·000	1·179
1	8	33·945	1·162
1	9	31·346	1·149
1	10	29·134	1·139
1	11	27·206	1·1285

Impurities.—The liquid hydrochloric acid of the shops has usually a yellow colour. This generally arises from the presence of some perchloride of iron, and occasionally from free chlorine. Dr. Thomas Thomson suspects that bromine may be present, partly because this substance is found in common salt, and partly because

a small quantity of this substance will give a similar colour to hydrochloric acid. The *chloride of iron* may be recognized by saturating the acid with soda or potash, and then adding the ferrocyanuret of potassium, which causes the formation of a blue colour (Prussian blue), if iron be present; an excess of caustic ammonia will also distinguish it, by precipitating a light brown peroxide of iron. *Free chlorine* is recognized by the power of the solution to dissolve leaf-gold. *Sulphuric acid* may be detected by a solution of the chloride of barium causing a white precipitate (sulphate of barytes), insoluble in acids and alkalies. In applying the last test, let the suspected acid be diluted with five or six times its volume of water, otherwise a fallacy may arise from the crystallization of the chloride of barium.

Physiological effects.—(*a.*) The *local* effects vary with the strength and quantity of the acid employed. In the *concentrated* form it acts as a corrosive poison; but is less powerful than either the sulphuric or nitric acids. The particular nature of its chemical action on the tissues is not so well known as either of the before-mentioned acids. Soon after swallowing it, thick white fumes of a pungent odour are evolved by the mouth. Like the other mineral acids, when thrown into the veins it kills, by coagulating the blood. When *diluted* it ceases to be corrosive, but acts as an irritant: hence, when swallowed, it excites a sensation of warmth in the throat and stomach.

(*b.*) Its *remote* action is very similar to that of sulphuric acid, already described. It has, however, been supposed to possess an exciting property with respect to the nervous and vascular systems.

Uses.—(*a.*) As a *local* agent, it has been employed in a dilute form as a gargle in aphtha, and other affections of the mouth, and also in ulcerated throats, especially of scarlet fever. Diluted with water, it has been applied to frost-bitten parts, to chilblains, &c. In the proportion of from 8 to 12 drops in three or four ounces of water, it has been employed as an injection in gonorrhœa. It has been employed both in the concentrated and dilute forms, in sloughing phagædena, but it is inferior to nitric acid.

(*b.*) Its *remote* uses are so similar to those of the dilute sulphuric acid, that it is hardly necessary to particularize individual cases. Suffice it, therefore, to say it has been used in fevers, (especially of the kind at one period called putrid), in gout, lithiasis, diseases of the stomach and liver, in venereal affections, &c. It does not so readily disorder the stomach as nitric acid, and in this respect agrees with sulphuric acid; it generally, however, causes a relaxed state of the bowels. In a very dilute form, and in the absence of common salt, it might be employed as an antidote in poisoning by the nitrate of silver.

Administration. — The most agreeable mode of exhibiting it internally is in the infusion of roses, substituting this acid for the sulphuric acid.

Antidote.—In a case of poisoning by liquid hydrochloric acid, the treatment would be precisely similar to that of poisoning by sulphuric acid. Chalk, whiting, magnesia, or soap, are the best antidotes. In the absence of these, oil and albuminous liquids of any kind might be given. The gastro-enteritis is, of course, to be combated in the usual way.

NITROHYDROCHLORIC ACID.

History and synonymes.—This liquid was formerly called *aqua regia*, or *nitromuriatic acid*. Its nature was first explained by Davy.

Preparation.—It is readily prepared by mixing 2 parts of hydrochloric acid with 1 part of nitric acid. In the arts, however, muriate of ammonia, or common salt, is often substituted for muriatic acid; or nitrate of potash for the nitric acid. By the re-action of the nitric and hydrochloric acids on each other, we obtain nitrous acid, chlorine, and water.

Reagents.	Results.
H Chl.	Chl.
$\overset{\cdot\cdot\cdot\cdot\cdot}{N}$	$\overset{\cdot\cdot\cdot\cdot}{N}$
	$\dot{H}$

Properties.—It has a yellowish or reddish tinge. Its most remarkable property is that of dissolving gold and platinum; metals that are insoluble, in either nitric or hydrochloric acids, separately.

Characteristic tests.—It is recognised by its colour, by its power of dissolving gold, by its precipitating a solution of nitrate of silver; the precipitate being insoluble in nitric acid, but soluble in ammonia; and by the production of two salts, a chloride and a nitrate, when an alkali is added to it.

Physiological effects.—It is a powerfully corrosive poison, acting in a similar manner to the nitric acid.

Uses.—It has been employed *internally* in the same cases as nitric acid, more especially syphilis, diseases of the liver, and some of the exanthemata. *Externally* it has been used as a bath, either local or general, in syphilis and hepatic affections. In India the whole body (the head excepted) is immersed, but in this country pediluvia only are usually employed, or merely sponging the body. The

nitro-muriatic bath is prepared in wooden tubs, by adding this acid to water, until the latter becomes as acid to the taste as vinegar. The patient should remain in the bath from 10 to 30 or 40 minutes. It excites tingling and pricking of the skin, and is said to affect the gums and salivary glands, causing plentiful ptyalism; indeed, we are told that without the latter effect, every trial is to be regarded as inconclusive. In the passage of biliary calculi this bath is said to be remarkably effective.

Antidote.—Poisoning by this acid is to be treated in the same way as that by nitric acid.

ON THE DIVISION OF STRICTURE IN STRANGULATED HERNIA, WITHOUT OPENING THE SAC.

To the Editor of the Medical Gazette.

SIR,

If you consider this communication of sufficient importance, I shall feel obliged by your affording it a place in your valuable journal. The subject is, the operation of dividing the stricture without opening the sac in strangulated hernia; an operation which at present is, in my opinion, by no means duly estimated by the profession, nor by any means so frequently performed as it ought to be. It was first, I believe, recommended by Jean Louis Petit, early in the eighteenth century; and it has subsequently met with the advocacy of several eminent practitioners. Mr. Lawrence, in his valuable Treatise on Hernia, 4th edit. p. 271, says, "the advantages of operating without opening the hernial sac are so great, in cases where the tumor exceeds a *moderate size*, that I strongly recommend its adoption in all such instances." But, at the present day, the merit of more particularly directing the attention of surgeons to it belongs to Mr. Key; who has not only pointed out, at some length, the advantages attending it, but has also pretty fully answered the objections which have been at different times brought forward against it. Still, however, surgeons seem to regard it as a dangerous innovation, and indicate the greatest disinclination to leave the older and more beaten track: more evidence on the subject, therefore, than has been hitherto adduced, appears to be required.

I fully concur in opinion with Mr. Key, that if the operation were more generally performed, it would be the means of preserving many lives. I consider that, if performed properly in all its steps, and at a sufficiently early period, it would divest the operation for strangulated hernia of a great part of its danger. It would moreover afford the surgeon, in many cases, the opportunity of operating under more favourable circumstances, as there are many, very many, patients who would submit to an early operation, if they could be assured that no danger would arise from it. So convinced am I of the safety of the operation, of the facility of performing it, as well as of the great danger of delay in cases of strangulated hernia, that if I were the subject of the complaint myself, I should beg, after the taxis, with the aid of the warm bath, and venesection, had been once fairly employed, unsuccessfully, by an experienced surgeon, to be operated on without the loss of another moment.

In the case the particulars of which I am about to narrate, although the operation was performed under very unfavourable circumstances, yet it was attended with complete success.

I was requested on October 4th, 1834, by Mr. Boote, surgeon, of Bedford Row, to visit a patient of his, who was suffering from strangulation of a scrotal hernia, on the left side. The patient was in his 80th year: the hernia was of many years' duration; and the symptoms of strangulation had existed for about 20 hours. The usual remedies had been employed, but without affording any relief. At the time I was called in the bowels were obstinately constipated, there was frequent vomiting of matter, much more like the contents of the small intestines than any thing to which we could compare it; the abdomen was tumid and tense; and the hernial tumor, which was of large size, was likewise tense, and extremely tender to the touch, particularly about the external ring. The pulse was not very much accelerated, but was very feeble and irregular, and the powers of the whole system were in an exceedingly depressed state. The countenance was shrunken, the complexion of a leaden hue, and the eyes glassy. Such symp-

toms co-existing with strangulated hernia, in a patient of such advanced age, were, I think it will be admitted, sufficient to exclude from the mind of even the most sanguine, any reasonable expectation that an operation, be it what it might, could afford relief. But, having to attend the hospital, I embraced the opportunity of mentioning the case to Messrs. Lawrence and Stanley, who agreed, that notwithstanding the great age, and desperate condition of the patient, it would be right he should have the chance of relief which an operation would give him. I therefore, fortified by their opinion, returned to my patient, determined, if I could gain his consent, and found that no particular change had taken place during my absence, to proceed at once to an operation. I found him very much in *statu quo*, and hopeless of recovery; but at the same time I experienced very little difficulty in persuading him to submit to the operation, as a means that might possibly relieve him, and which I informed him would be unattended with danger. I had made up my mind to operate by dividing the stricture without opening the sac; and as the hernia was of such long standing, I had no doubt of being able to accomplish my object. This, therefore, I proceeded, with the assistance of Mr. Boote, at once to do.

I commenced the incision of the skin about an inch above the external inguinal ring, and extended it downwards two inches and a half in front of the tumor. I then carefully dissected down to the tendon of the external oblique muscle, and to the sac, along the whole course of the wound. Having done this, I passed a slightly curved director under the edge of the ring, which, with a probe-pointed bistoury, I divided directly upwards, as far as seemed necessary to remove the source of strangulation. I then attempted to reduce the hernia, but found that there was still an impediment, which, on examination, proved to arise from the compression occasioned by two fine bands of unyielding fascial, or tendinous-like fibres, about a quarter of an inch from each other, extending across the neck of the sac, and to which they were so closely adherent as to be scarcely distinguishable from the sac itself. I therefore carefully divided them, having previously, and not without some difficulty, insinuated the flat end of a probe underneath them. I then made gentle pressure with both my hands on the tumor, which now, I had the satisfaction to find, readily yielded, the intestinal part of its contents returning with a gurgling sound into the abdomen. The patient was instantly sensible of relief. There still, however, remained some omentum down, which, as I found it was not easily to be returned, I resolved to leave in the sac without further interference. There was also evidently some fluid in the sac. The wound was closed with sutures and adhesive plaster in the usual way, the scrotum was supported, and the patient laid on his back in bed. A fomentation flannel was ordered to be kept constantly on the abdomen, a dose of calomel and opium was given at night, and a common clyster was directed to be administered every fourth hour, till the bowels were freely opened. The patient slept well, the bowels acted copiously in the course of the night, there was no recurrence of sickness, and in the morning he was able to take nourishment, and appeared almost as well as he could have been if the intestine had been returned without an operation. Not a bad symptom subsequently occurred: and on the third day I was able, with very little difficulty, to return the omentum into the abdomen; after which the parts were easily kept up by means of a compress and bandage. The wound healed by the first intention, and the fluid in the sac became quickly absorbed, so that on the Saturday following all was well, except that the small ulcers produced by the ligatures had not quite closed. But, on the subsequent Tuesday (the eleventh day from the operation), they had likewise healed, and I took leave of my patient, as well as he was before the operation. Since then he has constantly worn a truss, and not long ago he called on me to shew me that, notwithstanding his great age, he is able to walk about without inconvenience.

In dividing the stricture while the sac was entire I experienced no difficulty: indeed, though I proceeded most cautiously, the whole operation was completed in little more than three minutes.

That, if in this case the sac had been opened, as in the ordinary operation for

strangulated hernia, a fatal result would have taken place, I cannot have any doubt. I feel justified in this opinion, because in all the experience I have had in hospital and private practice, in cases treated by the most experienced surgeons, I never knew a patient under equally unfavourable circumstances recover. The rapidity too of the recovery in this case, unattended as it was by a bad symptom, may be, I consider, fairly attributed to the comparatively much slighter injury which by this mode of operating is inflicted on the system. That, however, patients often recover without the occurrence of a bad symptom after the sac has been opened, I am well aware. Indeed, of two patients in St. Bartholomew's hospital on whom I had operated for strangulated hernia, a short time before the above mentioned case, one recovered, if I may use the expression, almost without a symptom. The period of recovery, however, was much more protracted, occupying many weeks, and yet the operation was performed under circumstances much more favourable, and on a patient many years younger—ætat. 55.

In the other case just adverted to as occurring in the hospital, I operated by dividing, in the first instance, the stricture externally to the sac, which I accomplished, as in the first-mentioned case, without the slightest difficulty.

It was a case of large scrotal hernia, of long standing. The patient was ætatis 50, an habitually hard drinker, and an unhealthy subject. When I arrived at the hospital, I found that the strangulation had existed about eighteen hours; the abdomen was much distended, and very tender, as also was the hernial tumor; and the symptoms were altogether extremely urgent. The taxis, and all the usual means for the reduction of strangulated hernia, having been employed in vain, I at once proposed an operation to the patient, to which, as his sufferings were so great, he readily consented. But previous to the operation, I stated to the students that I considered the chances were very much against a favourable result, knowing that hard drinkers generally endure any serious injury very badly. I therefore determined to endeavour to remove the strangulation without opening the sac, believing that if this could be effected, the danger of the operation would be greatly diminished. It was evident that a large portion of intestine was contained in the hernial tumor.

In performing the operation, I commenced the incision some way above the external inguinal ring, which having fairly exposed, with such portion of the tendon of the external oblique muscle, as well as of the hernial sac, as corresponded with the wound in the skin, I freely divided its upper boundary, so as completely to remove all constriction made on the tumor by that part. I then endeavoured to return the hernia, but failed, in consequence of the unyielding condition of the neck of the sac. The sac was of its natural texture, except at its neck, where we thought it appeared slightly thickened. Under these circumstances I proceeded at once to open the sac; which having done, it was found that the external stricture had been wholly removed, and that the only impediment to reduction was in the neck of the sac; and here a mere touch, as it were, of the knife, effected all the division that was necessary; the unyielding and constricting part consisting of what appeared to be little more than a thread, or, if I may use the term, a mere ligature of fine tendinous fibre. The hernia was found to consist of about two feet of intestine, and a considerable portion of omentum: moreover, there were in the sac several ounces of serum. The intestine was of a dark chocolate colour, such as I have often observed when the mucous coat has suffered more in proportion than the serous. There were no adhesions; the parts were returned without difficulty; and the whole operation occupied a very short time—very little more than must have been the case if the sac had been opened in the first instance.

The case was subsequently treated in the customary manner, and for three days every thing went on more favourably than was expected. The bowels acted copiously, and the stomach retained what was taken into it. The distention, and some tenderness of the abdomen, however, continued; and subsequently the stomach became very irritable, and the bowels extremely irregular, being always in one extreme or the other—either greatly constipated, or too much open. These symptoms were combated by depletion local and general, by calomel and opium, by tepid

bathing, and by other means, such as appeared to be indicated, and always with temporary relief; but relapse after relapse occurred, till the patient, who had survived the operation about three weeks, was completely worn out. It should be observed that the wound in the sac did not unite by the first intention, but suppurated; which, of course, as the sac was very large, became a great additional source of constitutional disturbance: any serous cavity, of equal magnitude, highly inflamed, and in a state of suppuration, would, indeed, of itself often produce very serious symptoms.

From all I observed in the progress of the preceding case, I do not hesitate to state that, in my opinion, a different result would have probably followed, if it had been possible to effect the reduction of the hernia without opening the sac. The suppuration of the latter would then, undoubtedly, have been prevented.

Whether, after the stricture had been divided, I could have employed more force in the application of the taxis, if I may use the expression, or have had recourse to any other means with safety, to accomplish the reduction, I cannot say. It was the first time I had performed the operation which I am considering; I did not like the aspect of my patient; I was anxious that the operation should not acquire any disrepute in my hands; and I therefore determined to act with the greatest caution. The sac being so tense, and containing so large a quantity of fluid, obviously prevented me, so long as it was entire, and the constriction at its neck continued, from exerting much influence over the protruded intestine. But the great obstacle to reduction was undoubtedly the unyielding condition of the neck of the sac, and which, at the time of the operation, it certainly appeared impossible to remove without opening the sac. But this is a point to which I shall have occasion incidentally to revert presently.

The number of facts in connexion with this operation, which have been recorded, are so few, that it may be said to be yet quite in its infancy; and the course which should be pursued is by no means sufficiently established.

If another case, similar to the one which I have been just relating, should come under my care, I should not hesitate, after having completely removed all external stricture that was discoverable, and the texture of the sac appearing healthy, to place the patient in bed, in a position favourable for the return of the hernia, and be content for a time with employing very much the same means as if the reduction had been effected.

Of course I do not mean these observations to apply to every case of hernia that may occur. Among hospital patients, in particular, the practice must often be quite out of the question, in consequence of the long existence of the strangulation before they are brought in. A short time ago I had to operate on a patient in the hospital, in whom the strangulation had continued between ten and eleven days. The intestine, as was anticipated, was found in a state of gangrene. But it is a question with me, whether it would not be a more judicious mode of practice to adopt in many cases of hernia, than the course which is usually pursued; whether, in fact, it would not be better to be content at first with freely dividing the stricture, so as to place the protruded parts under circumstances favourable for their circulation being restored, and consequently in a state much fitter and easier to be subsequently returned into the abdomen. If the symptoms of strangulation continued, we might then, with very little pain to the patient, divide the neck of the sac.

I should in all cases of hernia make a point to employ only a very moderate force in my endeavour to effect reduction. When there is a large portion of swollen and inflamed intestine protruded, its reduction, even when it is exposed, is by no means an easy matter, unless the aperture in the tendon is extremely large. I have often seen the intestine greatly injured by the long-continued manipulation to which it has been found necessary to subject it before it could be returned. I have more than once known the intestine (one of the ablest and most experienced surgeons being the operator) feel quite cold before its return could be accomplished. The difficulty sometimes arises from a tympanitic condition of the abdomen, but much more frequently, I believe, from the increased volume of the protruded parts. The thickening of a strangulated portion of intestine is produced, as it appears to me, in great

measure, by an infiltration of serum into its cellular tissue, which, when the strangulation is removed, would in all probability become quickly absorbed, a great diminution consequently take place in the bulk of the hernia, and thus its reduction be much facilitated.

By pursuing the course which I am advocating, much of the danger and difficulty attending cases of strangulated hernia would, I conceive, be obviated. I should always, as I have stated before, freely divide the stricture — so freely that the protruded parts, if they had acquired no adventitious adhesions, might in general, after waiting a little, be readily and easily replaced. Thus the injury that so often arises from exposure and manipulation would be avoided. The chance of a radical cure (that is, of such a complete cure that there would be subsequently no necessity to wear a truss) is always so slight, that it should never influence our mode of operating, nor ever deter us from so thoroughly releasing the intestine that it may be returned without force. Whenever the operation has been performed, there is no condition of the ring itself that will prevent the future recurrence of the hernia. Its subsequent descent can, I believe, only be prevented by adhesions contracted about the neighbourhood of the ring, or in some part of the cavity of the abdomen. There is no probability that any new structure could form, by which any of the apertures through which herniæ protrude could be so firmly and effectually closed, as to be rendered capable of withstanding the pressure exerted on the viscera by the abdominal muscles. I know, therefore, of no good reason for not dilating the ring to the fullest extent required. The sac I should never attempt to return; it is almost certain that it will have contracted adhesions to the contiguous parts; nor, the intestine being replaced, should I be very solicitous about any portion of omentum that remained. Indeed, if with the return of the intestine only, the symptoms of strangulation had subsided, I should consider the patient in a condition almost as free from danger, *cæteris paribus*, as in a case in which the reduction had been effected entirely by the taxis. If ulceration, or spacetation of a portion, however small, of intestine had taken place at the strictured part, there would most likely be such adhesions within the ring, that it would be quite impossible to effect reduction without greater force than it is at all probable any surgeon of the present day would feel justified in employing. I should, therefore, have no apprehensions on this head.

A portion of intestine may remain in a hernial sac irreducible, or simply incarcerated, for years, without the production of any bad symptoms: the stomach, notwithstanding, will continue retentive, the bowels act regularly, and every thing go on well. In a case of hernia, therefore, in which the strangulation has been completely removed, before the intestine has undergone any irrecoverable change, there would, in my opinion, be much less danger from the continuance of its mere displacement for a short time, than from its exposure during long-continued manipulation, however judiciously and carefully employed, in the attempt to reduce it. If left to itself, in the manner I have before described, and all impediment had been removed, it is very possible that in a short time the reduction might be effected by the "vis medicatrix naturæ," or call it what you will; perhaps it would be more correct to say, by its own unassisted and unimpeded action, which no doubt would be pretty vigorously exerted as soon as the circulation became completely restored. Whoever has witnessed, in a living animal, the great force exerted by the peristaltic action of the intestines, can hardly doubt its power to replace within the abdomen a portion of protruded intestine, if free from constriction and adhesions. It is not uncommon, in cases of large hernia, after urgent symptoms of strangulation have long existed, to witness the reduction, spontaneously, as it were, take place. A short time ago I was sent for to the hospital, to operate in a case which had been long strangulated; but when I arrived, I found the hernia had just gone up as the patient was being carried into the operating theatre. Cases, too, are recorded, in which portions of omentum, which could not be returned during an operation, in consequence of adhesions, have in a few days spontaneously receded into the abdomen. And in cases in which there have been no symptoms of strangulation, it is by no means very uncommon to fail in the reduction of a hernia one day, which on another will

be accomplished with the greatest facility. I feel, therefore, that under the circumstances I have stated, there would, in the generality of cases, be no dang r in allowing a short time to elapse after the division of the stricture, before any attempt was made by manipulation to effect reduction: but having failed to relieve my patient while the sac was entire, I of course should open it; and having examined its contents, act according to circumstances. I do not consider, as I stated before, that if all constriction had been previously removed, any mischief could arise from the little delay.

It should have been stated, that in performing the operation in question, we ought always to be most careful, to clear as far as possible, all external matter—condensed cellular substance, tendinous, like fibres, &c., from the neck of the sac. Without this precaution the operation would, I believe, often fail, and fail solely from this cause: too much attention, therefore, cannot be paid to this point. A person who had not witnessed it would scarcely believe how completely a few delicate fibres embracing its neck, but hardly distinguishable from the sac itself, will prevent the reduction of a hernia. A cause slight as this certainly operated prejudicially in the second case which I have related in this communication. From the investigation I have made on the subject, it is possible, I believe, in many cases, to remove the constricting or condensed matter from the neck of a hernial sac, without injury to the sac itself. I have seen this to be the case even when such substance has existed in the form of a band or bands, and been so closely adherent as to appear at first that it was an alteration in the tissue of the peritoneum itself. The proceeding will of course protract the operation a little; but the additional time will have been well spent, if it save the necessity of opening the sac: and if the sac should be wounded in doing it, the patient will be no worse off than if it had been intentionally divided in the first instance. And here let me ask, why should surgeons be on all occasions so anxious to see the contents of the sac in a case of strangulated hernia? What surgeon is there who would hesitate to return by the taxis, if it were in his power, any hernia, however protracted the period of strangulation? And why should the mere division of the stricture render it indispensable that the hernia should be seen?

I have heard it said, and very lately, that the opening of the sac does not add much to the patient's danger. But, in answer to that I would inquire, is it a matter of trifling importance, not only to expose, but to roughly manipulate, as is too often the case, a large portion of inflamed and exquisitely tender intestine? Again, let me inquire, would a surgeon, having a clean cut wound, of two or three inches in length, through the parietes of the abdomen, *the peritoneum being uninjured*, consider himself in danger? And, on the contrary, who would not feel that he was in the greatest danger, if at the same time his *peritoneum were wounded* to any thing like the same extent?

Perhaps some will say, that in returning the hernia unseen there may be greater danger than would arise from dividing the sac. I would reply to that by saying, that in the one case the danger is contingent — in the other certain.

I shall not on this occasion discuss the subject further: indeed I have only gone thus far into it, because I know, from observations I have heard them make, that there are many able surgeons who still decidedly object to the operation, and object to it entirely, I believe, because they have not given it sufficient consideration.

I am, sir,
Your obedient servant,
E. A. Lloyd,
Assistant-Surgeon to St. Bartholomew's Hospital, and Surgeon to Christ's Hospital.

Bedford-Row, March 11, 1836.

NON-EFFECT OF MARRIAGE ON THE DURATION OF LIFE.

To the Editor of the Medical Gazette.

Sir,

The present age seems to be distinguished from former times by an inordinate appetite for discovering what is new and surprising; and this, aided by the modern habit of printing and circulating all such novelties without much consideration, becomes an obstacle to the steady progress of knowledge, which

must alway depend on knowledge already acquired,—and is disturbed and retarded by every imaginary discovery of error in that which may have previously obtained universal credence in the scientific world. Hence it behoves every man who thinks he has made a discovery subversive, or even derogatory of received knowledge, to announce it with diffidence, or not at all, until after mature consideration.

I cannot but think that Dr. Casper has offended against this salutary rule, in his "Essay on the Influence of Marriage on the Duration of Human Life," recently published in the *Annales d'Hygiène Publique;* an essay which you have noticed in your journal, and in such manner as to call for that degree of examination which such an astonishing announcement must undergo, before it can be admitted into the storehouse of ascertained facts.

For all the labour and all the arithmetic which has been accumulated for the purpose of establishing tables of mortality, is sadly depreciated, if, by a mere change from celibacy to marriage, which depends on the will and pleasure of individuals, the duration of human life is prolonged in any such degree as you have stated, on the authority of Dr. Casper. If well founded, every couple intending to marry, or recently married, are able, by purchase of an annuity at the market price, to profit unjustly at the expense of the unmarried part of the community; and the evil of such injustice is of the greater magnitude as being incapable of remedy, and permanently subversive of the vast benefit to civilized man derived from the knowledge (or, must I now say, the *supposed* knowledge?) of the average duration of human life throughout all the respectable classes of society, who are now encouraged, by means of life-assurance offices, to provide for their families, to live without anxiety, and to die in peace.

In England, for instance, I thought we had arrived at reasonable certainty of the increasing duration of human life throughout the last century, and almost at absolute certainty of its present value; the three tables of modern life, inserted in your journal (vol. xvi. p. 585), having been founded on various and extensive materials, and by persons far from acting in concert with each other; yet the insurable (usually insured) ages in these tables differ not from each other, beyond such fractional parts of a year, as for practical purposes are of no importance whatever. But this mighty structure is now in danger of demolition; and in defence of it, I must endeavour to convince Dr. Casper that he has advanced an exaggerated opinion of the superior duration of married life. Previously to the publication of such an opinion, he might have extended his thoughts farther than to mankind—to those domestic and civilized animals which approach nearest to man in intellect, and, in all the attributes of our physical nature, in flesh and blood, in bone and muscle, betray no difference whatever. Over the power of generation in some of these animals—the dog and the horse, for instance—man possesses, and has exercised, despotic sway in all ages of the world. The females of these animals (all such as deemed valuable) have been permitted to produce progeny, or to remain barren, at the will of their owner; and yet, after millions of instances, affording obvious comparison, it has never been suspected that a mare lives the longer from having produced colts, or a female hound, pointer, or spaniel, from breeding and suckling numerous litters of puppies: in the latter case the animal is rather supposed to be exhausted, and old age accelerated.

But if the life of a brood mare has never yet been supposed to surpass that of barren mares, how much more convincing is the case of nine males in ten of this species of animal, who are deprived of generative power soon after birth, and yet are never supposed to lose or gain duration of life as compared to the entire male of their own species. All things combine in proving to us that nature is replete with a plastic power of accommodation beyond our comprehension, and that a vast variety of treatment and of habit is compatible with the well-being of every animal; so that in our own case—in the case of man—we encounter no dissent from the proverb, "that custom is a second nature."

Speculation has always been afloat, as to the injurious or beneficial effect of marriage, child-bearing, and its consequences, on female life, and suffrages have been divided on this question; but Dr. Casper attributes superior longevity to the married man as well as to the married female; although, after dis-

serting at some length upon the moral and domestic arguments which he thinks make for or against his own opinion, as regarding both sexes *(le pour et le contre)*, he arrives at no decided preference. But he cannot seriously attribute such absolute chastity, or excessive sexual indulgence, to the generality of unmarried males, as to affect the usual duration of life in the mass; so that his opinion must be weighed and valued according to the old-fashioned evidence of facts; and of these he has produced none, except those which appear in the Essay of Deparcieux, under the title of *État des Morts* published by M. Languet, parish priest of S. Sulpice, in Paris. This meritorious pastor (whose name is preserved from oblivion in the *additional* Essay of Deparcieux) recorded during thirty years (1715 to 1744) no less than 48,540 burials, with the ages of the deceased, distinguishing the unmarried, married, and widowed: but the ages of the deceased prove absolutely nothing of the current rate of mortality, unless we also know the number and ages of the living at the same time and place, and of the several classes distinguished in the S. Sulpice statement of mortality.

I do not presume to incroach upon the patience of your readers in proving that the number of the living is requisite for ascertaining the rate of mortality, which can only be obtained by dividing the living of any given age or condition by the number of the same given age or condition who die annually, or in any longer given period; and of this nobody is more fully aware than Dr. Casper, who, having said that 31 unmarried males *(garçons)* die, while only 3 (or 2·8 more exactly) of the married die in a given period, goes on to say, "but this difference is merely in appearance, since few men become husbands under 30 years of age*;" and thus if there are 10 or 11 existing bachelors *(garçons)* to 1 married man, the actual mortality of both classes (as above stated by Dr. Casper), is the same; moreover, Deparcieux assigns reason for an unusual preponderance of unmarried young men in the parish of S. Sulpice, as containing many large *hotels* (town-houses) of the nobility, who kept numerous retinues of male servants. But no such startling disparity as 10 or 11 to 1, really appears in the mortuary register of S. Sulpice, wherein the burials of bachelors *(garçons)* of 10 to 30 years appear to have been 1110; of the married, *(hommes mariés)* 180; of widowers, *(veufs)* 3; so that the 1110 divided by 183, gives no more than six to one. In plain truth, Dr. Casper has deceived himself and his readers, by exhibiting a per centage calculation, where such calculation is inapplicable, and could not fail to produce an erroneous result. In this manner he has been led to state the burials of the unmarried as compared to the married, (30 to 45 years of age) as 27 to 18, or 3 to 2; whereas the actual difference is quite adverse to his argument, being 975 to 1232; as three to four in favour of the *unmarried*. For the sake of brevity, I subjoin a comparative view of the per centages of Dr. Casper, and the actual number of burials in each period of human life, as distinguished in the S. Sulpice register:—

Epoque de la Vie.	According to Dr. Casper.		According to the S. Sulpice Register.		
	Hommes non Mariés.	Hommes Mariés.	Garçons.	Hommes Mariés + Veufs.	H. M. et Veufs.
From 20 to 30 years	31·3	2·8	1110	180 + 3 =	183
— 30 to 45 —	27·4	18·9	975	1205 + 27 =	1232
— 45 to 50 —	18·7	30·2	664	1851 + 111 =	1962
— 60 to 70 —	11·5	20·9	410	983 + 375 =	1358
— 70 to 80 —	7·5	18·2	267	651 + 535 =	1186
— 80 to 90 —	3·0	7·8	108	192 + 315 =	507
— 90 to 100 —	0·5	0·9	12	6 + 15 =	21

* "Mais cette différence n'est qu'apparente, puisque peu d'hommes se mariaient avant trente ans."

I must here mention that as Dr. Casper (consistently with the scope of his argument) has included widowers with married men, as having had the benefit of marriage, I have inserted a total of the two corresponding columns in the S. Sulpice register accordingly; and as Dr. Casper produces no other distinct authority in support of the superior longevity of this combined class of males, I may here close the question as to the male sex, merely repeating, that a mortuary register unaccompanied by enumeration of the living, furnishes no basis on which to calculate the rate of mortality; moreover, that Dr. Casper has misinterpreted the document on which only he relies; so that I avoid asking you to incumber your pages with a female table answerable to the foregoing table of male life, and dismiss for the present the S. Sulpice register.

But regarding female life, Dr. Casper produces two other authorities, and I am sorry that to the last of these (that of M. Biches) I have no opportunity of access; but this is of the less importance, as Dr. Casper says he has abstracted from it a table *analogous* to that from the S. Sulpice register; so that the table of mortality thus extracted from the materials furnished by M. Biches is of no value, whatever may be the value of the facts recorded by the last named author.

I now recur to the table of Dr. Odier, who has calculated for himself, and unquestionably with perfect good faith; for at 60 years of age he finds the expectation of life of married and unmarried females to differ but half a year, (13·02 to 12·53) and at higher ages the advantage is alternate and inconsiderable. These facts are somewhat inconsistent with the superior longevity ascribed to the married female. Moreover, it was customary on the Continent, and long after the date of Dr. Odier's publication, (which appeared in the year 1814) to calculate the expectation of life without reference to increase or decrease of population; so that the causes suggested by Dr. Odier for the longevity of married females, and the commentary of Dr. Casper upon them, are somewhat gratuitous. But we must always speak respectfully of Dr. Odier, who has deserved well of the scientific public by his laborious and intelligent classification of the registers of Geneva and its suburbs.

Half a century earlier (in 1766) M. Muret undertook researches in the Pay de Vaud, with a special view to the comparison of female life, of the married and unmarried female; and he published the result in a Memoire, which sufficiently establishes the acuteness of its author, who yet laboured under the same defect of inattention to the movement of population; as is proved by his tables, which exhibit the annual rate of mortality to be different from the expectation of life at birth, representing the first as at 1 in 40, the last as 35 years, in ten parishes or districts of the Pay de Vaud*. Yet the Memoire of M. Muret is highly worthy of the attention bestowed on it by our own countryman, Mr. Milne, in his discussion "on the difference in the rate of mortality among the married and the single," in his Treatise on Annuities and Life Assurances, pp. 762–781, in which it appears that the radical error of M. Muret (additional to that already mentioned) arises from his supposing that all females who are married between 15 and 20 years of their age, are married equally (one-fifth) in each of these years; whereas very few girls are married in their 16th or 17th year, as compared with the number who marry in the three next years of life; and if we may suppose none to have married in their 16th or 17th year, M. Muret's mortality of the married must be increased as 5 to 3; and a much less correction than this is sufficient to invalidate all his conclusions.

What, then, shall we finally conclude as to female mortality? Does it really differ in favour of the married, or of the unmarried female? It is not a little remarkable that Deparcieux, who is so confidently quoted by Dr. Casper, as maintaining the superior longevity of married females, has furnished the best materials for negativing the question,—materials, indeed, no longer renewable, because dependent on the existence of monastic orders, male and female; but so unimpeachable and particular, that every individual is pursued through life, as in a Life Assurance, or a Government Annuity Office,—forming, indeed, the only unquestionable part of Deparcieux's justly celebrated Essai; for the lives of his tontinists being in classes,

* This difference of five years would result from such a moderately increasing population as might double itself in about 100 years.

may be diversely considered and investigated, and from the details furnished in his Essai, have been subjected to correction, according to the views of various authors who have since treated on the expectation of human life. But with regard to his monks and nuns, he had to calculate on a collection of single lives, and his results are not liable to contradiction. I subjoin a comparative table, not different from the essential part of his large Table XIII. but condensed (for the convenience of your pages) by combining, in an average column of monks, all those which are inserted by M. Deparcieux in four columns. I must also premise, that he supposes tontinists to lose 186 in 1000 of their number before they arrive at the age of 20, 814 then remaining alive; and this being also the time of life when the religious of both sexes usually took the vow of chastity, the comparison is instituted at that age, and is continued throughout life in the following table:—

	1.		2.		3.		4.		
Ages.	Tontine Annuitants. — Both Sexes.	Decrements.	Monastic Orders. — Males.	Decrements.	Monastic Orders. — Females.	Decrements.	Monastic Orders. — Both Sexes.	Decrements.	Ages.

						2		1	

From the extreme scarcity of M. Deparcieux's Essai, it becomes proper to describe the three first columns in his own words:—(1.) *Ordre établi sur les listes des tontines de* 1689 *et* 1696—(2.) *Ordre établi d'après plusieurs religieux, morts depuis* 1685 *jusqu'au milieu de* 1745—(3.) *Ordre établi d'après plusieurs religieuses, mortes depuis* 1685 *jusqu'au milieu de* 1745; and for the same reason, I may be permitted to add, that Deparcieux's Observation on An-

nuitants is founded on 5911 tontinists of 1689, and 3349 of 1696; in all, 9260 annuitants: his observation on monastic orders is founded on 9970 religious; the annuitants, as well as the religious of both sexes, being mostly inhabitants of Paris.

It will be manifest from the foregoing table, that until the age of 50 (when the consequences of marriage on the female may be said to cease), the survivors of the religious (both sexes) who live in celibacy, outnumber the annuitants, most of whom, no doubt, were married persons; after the age of 55, the surviving annuitants outnumber the female religious until the age of 90; at and after which, survivorship is in favour of celibacy. The effect of this alternate superiority cannot be exactly represented, otherwise than by a table of the comparative expectancy of life at all the specified ages; and I subjoin such table accordingly,—substituting, as more convenient, *decimal* parts of the year, in place of the *months* used by Deparcieux:—

Ages.	Annuitants. Both Sexes.	Religious. Both Sexes.	Religious. Males.	Religious. Females.	Ages.
20	40·25	39·16	38·16	40·17	20
25	37·17	35·64	34·61	36·67	25
30	34·08	32·08	31·00	33·17	30
35	30·92	28·54	27·42	29·67	35
40	27·50	25·10	23·95	26·25	40
45	23·92	21·73	20·55	22·92	45
50	20·42	18·43	17·36	19·50	50
55	17·25	15·35	14·46	16·25	55
60	14·25	12·46	11·67	13·25	60
65	11·25	9·96	9·09	10·83	65
70	8·67	7·65	6·88	8·42	70
75	6·50	5·66	5·07	6·25	75
80	4·67	4·10	3·62	4·58	80
85	3·17	3·35	2·79	3·92	85
90	1·75	2·79	2·33	3·25	90
95	—	1·00	—	2·00	95

It is manifest, on consideration of the two foregoing tables, that celibacy and marriage are so equally compatible with the duration of human life, that the calculations of insurance offices remain equally valid whether the individuals insured are married or unmarried; and the same salutary truth is applicable to the annuities granted by government; nor is it less satisfactory to perceive that nature is so constant and so powerful in her purposes, that the comparative expectancy of life in the male and female religious, differs in favour of the latter in the same degree as in secular life. Deparcieux, perceiving that religious life has an advantage as far as the 45th year of life, afterwards a disadvantage, endeavours to explain it by the selection of novices, who are not suffered to take the vows unless they are perfect in bodily health and organization; but after they have been fifteen or twenty years in a convent, he thinks they begin to experience the unfavourable effect of too frequent fastings, of nocturnal hours of devotion, and of voluntary discipline and austerities sometimes excessive,—reasons which will excite the smile of those who have imbibed the popular disbelief of strict regularity among the monastic orders, which yet was in fact seldom violated; but the effect of the many amusing fables of misconduct imputed to monks and nuns is irresistible. It really seems to result from the severe inquiry into this subject in the time of Henry VIII., that irregularity was not uncommon in the smaller communities, but that the abbeys and large priories of both sexes were well governed, and irreproachable.

I will not close this letter without giving a view of married life, of the comparative numbers of the married and unmarried; and this appears, on a large scale (in the Spanish enumeration of 10,541,221 persons, in 1797), to have been in the following proportions:—

	Males.	Females	
The unmarried (*solteros*)	28	28	Per cent. on the population.
The married (*casados*)	19	19	
The widowed (*viudos*)	2	4	
	49	51	

Having relied so much on M. Deparcieux's facts in refutation of Dr. Casper's Essay, I am bound to notice the opinion (not a decided opinion) of the former, in favour of married life, as quoted by Dr. Casper, and founded on the statement of mortality in the parish of S. Sulpice*. But this statement was not published until the Essay of M. Deparcieux was in the press (*sous la presse, et bien avancé*); and the latter was thus betrayed into hazarding a hasty suggestion, concerning which I shall take the liberty to quote the unanswerable remark of Mr. Milne (page 771 of his Treatise), than whom no person has mentioned the labours of M. Deparcieux with more respect:—

"The statement of mortality in the parish of S. Sulpice shews that the number of deaths of bachelors above 20 years of age was a little more than half the number of husbands and widowers who died above that age; while the number of bachelors who died above the age of 90, was but one-seventh of the number of husbands and widowers who survived the same age.

"And the number of maids who died above the age of 20, was nearly one-fourth the number of wives and widows who died above that age; while the number of maids who died above 90, was only one-eighth the number of wives and widows who survived the same age.

"Hence M. Deparcieux inferred, that of the persons of both sexes who survived 20 years of age, those who married lived longer than such as remained single. But this conclusion does not necessarily follow from the premises.

"To illustrate this, let us suppose that all who were born in one place, which we will call the country of the single, removed at their marriage into another country, which, therefore, we will call that of the married: then it will be evident that in the country of the single, a less, and in that of the married, a greater proportion of the living who had passed their 20th year, would be above the age of 90, than if the population had been stationary, and not affected by migration.

"Therefore, although the law of mortality in both these countries had been the same, of those who died above 20 years of age, a less proportion would be past 90 in the country of the single than in that of the married. So that the above statement from the register of S. Sulpice does not enable us to draw any satisfactory inference with regard to the effect of matrimony upon longevity, nor even to compare the mortality among the married to that among the single."

On perusal of what I have written in this long epistle, I am persuaded that I shall not incur the displeasure of Dr. Casper, or of any other lover of truth, by my foregoing examination of his Essay. May I venture further to hint to yourself, as a public journalist, that the announcement of such an incredible discovery should have been delayed until you had satisfied yourself of the validity of the facts and of the calculations adduced by Dr. Casper.

I remain, sir,
Your most obedient servant,
JOHN RICKMAN.

March 5, 1836.

* Dr. Casper is not satisfied with it: "Le savant (Deparcieux) dit seulement, incidemment, et sans pousser ses recherches sur une différence si frappante." But no such alarming difference existed until it was created by Dr. Casper's erroneous calculation.

STATISTICS OF THE ST. MARYLEBONE INFIRMARY, FOR THE YEAR ENDING DEC. 1, 1835;

With Observations.

By John Clendinning, A.M. M.D.

Fellow of the Royal College of Physicians; Fellow and Hon. Sec. Royal Medico-Chirurgical Society; and one of the Physicians to the Infirmary.

[Concluded from p. 935.]

But the difference between the late year's results at the Marylebone Infirmary and those of former years, however considerable, is by no means equal to what I find to obtain between the Infirmary and other medical charities in this city, of a more general nature. I have been favoured, through the kindness of various friends, with statements respecting St. George's, the Middlesex, the Westminster, and the London Hospitals, embracing a period of twelve months, ending December 1, 1835; from which it appears that the highest ratio borne by the deaths to the admissions, in any of them, for the last year, was about 10 per cent., while the lowest mortality I observe amongst them—viz. 7 per cent.—is full one-half less than that of last year at the Infirmary. The following table contains all the particulars to be depended on, that I have been able to procure, respecting the working of those great establishments for the period mentioned; and a perusal of that table will not only define the problem—viz. the relatively high mortality of the Infirmary—but also give the solution. I have appended, for facility of comparison, analogous statements from the Marylebone, Pancras, and St. George's Infirmaries. *(See next page.)*

Now I imagine the explanation of the superior mortality of the Infirmary may be gathered easily enough from the preceding table; especially from columns 2, 3, 4, 6, and 7.

From column 2, or Ratio of Deaths by Phthisis to other Deaths, it appears that the highest mortality by consumption, of those hospitals, was last year 13·33 per cent., instead of 33 per cent. as at the Infirmary. Now of this difference in the ratio of phthisical cases, there can be no cause other than differences in the relative facilities of admission into the hospitals in question. The general hospitals usually decline admitting cases of confirmed consumption, or else discharge them after a few weeks or months of unsuccessful treatment, from a feeling that the paramount duty of those establishments is to relieve the sufferings of as large a number of the sick poor as their domestic and pecuniary resources will admit of, and that the parochial Infirmaries are the proper asylums for such hopeless cases; while, on the other hand, the latter institutions are maintained for the express purpose of sheltering all destitute sick persons, having legal claims on their parishes. The practical statistical effect of this difference in the facilities of admission respectively, is, that in the records of the general hospitals, the disease which produces from 20 to 25 per cent. of all the deaths in this country, furnishes but a small item; whereas the parochial infirmaries present even more than a full proportion of phthisical mortality: the excess, however, being easily explained by the necessarily impoverishing effect, amongst the working class, of a very debilitating and very tedious disease.

From column 3, we see the greatest loss of patients above 60, in the general Hospitals, was 13 to 14 per cent., instead of 35 per cent., as at the Infirmary. No. 4, again, which at the Infirmary amounted to 9 per cent., was 2-3rds lower at the London, and 9-10ths at the Westminster. Now the greater intensity of mortality, or less tenacity of life, of very young and of aged sufferers, from sickness of whatever kind, is tolerably notorious. Mr. Finlaison's Report of 1829 is well known, at least its results; and the views of Mr. Rickman and Mr. Edmonds are familiar to the readers of the medical weekly journals: the latter gentleman, in particular, has very recently and very ably, as it appears to me, elucidated the question respecting the influence of age on the mortality of sickness, in the pages of the Lancet.

Nos. 6 and 7 show the great predominance of surgical cases in the general hospitals, and, on the contrary, the prevalence of medical cases in the infirmaries, where preference and selection are wholly excluded; and they show, at the same time, though indirectly, the more grave character of medical cases, whose average mortality appears considerably

COMPARATIVE VIEW OF THE MORTALITIES OF SEVEN GENERAL HOSPITALS AND PAROCHIAL INFIRMARIES OF LONDON,

For the Year ending December 1, 1835.

	Ratio of Deaths to Admissions.	Ratio of Deaths by Phthisis to all other Deaths.	Ratio of Deaths of Persons above 60 to total Deaths.	Ratio of Deaths under 5 years to total Deaths.	Ratio of Fatal Accidents to total Accidents.	Ratio of Medical to Surgical Cases.	Ratio of Medical to Surgical Mortality.
London Hospital	1 in 11= 9 per cent.	1 in 9= 11 per cent.	1 in 7·50= 13·33 per cent.	1 in 30·75= 3·25 per cent.	1 in 11= 9 per cent.	as 2 to 3	as 11 to 9
St. George's Hospital	1 in 10= 10 per cent.	1 in 24= 4·25 per cent.	unknown.	unknown.	1 in 10= 10 per cent.	as 5 to 9	as 11 to 7
Middlesex Hospital	1 in 14·33= 6·66 per cent.	unknown.	unknown.	unknown.	unknown.	as 2 to 3	as 7·25 to 5
Westminster Hospital	1 in 10= 10 per cent.	1 in 7·50= 13·33 per cent.	1 in 14= 7 per cent.	1 per cent.	1 in 8·33= 12 per cent.	equal	as 7 to 3·75
St. Marylebone Infirmary	1 in 6·66= 15 per cent.	1 in 3= 33 per cent.	1 in 2·90= 34·50 per cent.	1 in 11·25= 9 per cent.	unknown.	as 11 to 8	as 8·25 to 1
St. Pancras Infirmary	1 in 7·66= 13 per cent.	unknown.	1 in 2·66= 37·50 per cent.	1 in 14= 7·20 per cent.	unknown.	as 4·66 to 1	unknown.
St. George's Infirmary	1 in 4·25= 23·50 p. cent.	1 in 3·20= 33 per cent.	1 in 3·11= 32 per cent.	1 in 19= 5·25 per cent.	unknown.	as 10 to 9·16	as 11 to 1

Note.—The ratios in the table have been deduced from corresponding totals, obtained from official sources, and now in my possession, but which I have thought it unnecessary to publish, and have therefore not included in the table.—J. C.

to exceed that even of surgical accidents. It is a law not sufficiently known, I imagine, that the mortality of general hospitals is, *cæteris paribus*, directly in the ratio of the prevalence of medical cases, and inversely, up to a certain point, in the ratio of that of surgical cases, relatively to the total of cases admitted. To explain this by a few facts, I subjoin the following table, extracted from the *Resumé des Comptes Moraux*, for 1822:—

	TOTAL ADMISSIONS.		TOTAL DEAD.		RELATIVE MORTALITIES, MEDICAL & SURGICAL.
	Total Medical.	Total Surgical.	Medical Deaths.	Surgical Deaths.	
La Charité........	2933	867	515	80	Medical mortality= 19 per cent. Surgical mortality= 10 per cent.
Hôtel Dieu........	8807	2722	1471	219	Medical mortality= 16 per cent. Surgical mortality= 8 per cent.
La Pitié	4070	1142	580	53	Medical mortality= 14 per cent. Surgical mortality= 4·80 per cent.

It appears also, from the same authority, that the mortality of the Hôpital des Enfans Malades, which contains 550 beds, was as follows:—On a total including those continued from the preceding year (viz. 417) = 3509, the medical mortality was 1 in 3·41, and the surgical ditto but 1 in 7·10.

Now it is obvious, from the largeness of the numbers in the preceding tables, and the absence of any predominant professional influence in the administration of the Parisian hospitals, and, indeed, from obvious *à priori* considerations, that the results of that table are not, *by any accident*, different from those of any similarly constructed tables of London hospital results.

1. The *à priori* consideration is the obvious one, that medical diseases are principally lesions of vital parts; of the functions of the great viscera of the head, chest, and abdomen, and of the crasis of the vital fluids: whereas surgical diseases proper, are, for the most part, injuries or defects of parts external, and not absolutely and immediately necessary to animal existence.

2. The total beds of those three hospitals is 1900 (a number equal to four-fifths of the beds of the eight principal hospitals of this city), and the total of in-patients considerably exceeds 20,000; an amount little inferior to that of the in-door cases of the same eight London charities.

3. Then the admissions into the Parisian establishments named in the table, includes all cases, in whatever stages, and without distinction; with the exception of young children, lunatics, incurables, (in the broadest sense of that term), venereals, and lying-in women; for each of which classes the French government has provided a peculiar asylum, under the same administration with the hospitals in question; as appears from late Nos. of the Journal Hebdomadaire and Gazette Médicale.

In like manner, for this island, I may cite, in proof of the superior gravity of medical diseases, the Report of the Royal Infirmary of Glasgow, for 1827, the only one at present at hand; which gives the medical mortality about 11 per cent., and the surgical 7 per cent. only; and a statement for the last year (ending December 1st, last), in my possession, from which it appears that the medical mortality was 10·66, while the surgical mortality was only 4·80 per cent., at the Middlesex Hospital.

If I had succeeded in procuring sufficient data to enable me to include St. Bartholomew's, St. Thomas's, and Guy's Hospitals, in the table of London hospitals, I should further have to insist on the large proportion of venereals they contain, as a cause of their relatively small mortalities. St. Bartholomew's contains, I understand, 130 beds for venereals, and St. Thomas's about 100; so that probably, in each, not less than from 15 to 20 per cent. of their annual admissions consist of venereal cases. Now, from the "Recherches Statistiques," published by order of Mons. De Chabrol, in 1821, it appears that for ten years, ending with 1813, the average mortalities of several of the principal hospitals of Paris was as follows:—Hôtel Dieu, 1 in 4·93; La Pitié, 1 in 5; La Charité, 1 in 7·80; while, for the same period, the mortality of the Hôpital des Vénériens was, for adults, about 1 in 60, and for infants only considerable—viz. 1 in 2·50: and, from a statement with which I have been favoured from the Grosvenor Place or Lock Hospital, it appears that, for the year ending 1st December last, the deaths recorded on a total of 445 cases were but 3. The four general hospitals from which I have been able to procure adequate statements, admit few or no venereal cases, and the parochial infirmaries have comparatively few applications on account of venereal disease. The number of venereals in the Marylebone Infirmary is under 100 annually.

In addition to the preceding causes of inferior mortality, and consequently of apparently more successful treatment in the general hospitals, as compared with parochial infirmaries, which my data have enabled me to identify, there are others of whose existence I have no doubt, but which I am unable to estimate in numbers with any approach to accuracy. I allude more especially to the more advantageous condition of the subjects admitted by general hospitals in point of age. The salaried, and therefore practically responsible, officers of those charities are not required by their employers to keep such official records as will serve the purposes of the statistical pioneer of medical science; there is usually no sufficiently accurate account of the trades, duration of sickness, diseases, &c. of the patients, kept in the official journals; and even the ages are often neglected. This last is an especially important item in the account, and should never be omitted. Owing, however, to my inability to procure sufficient data, I have not been able to contrast the table of ages of cases admitted into the Infirmary, with similar tables from the general charities, and have been prevented from in that way accounting numerically for a considerable share of the excess of the Marylebone mortality above those of the general hospitals. I shall, therefore, merely extract a few particulars from the records of military medical practice, for the purpose of shewing what is apparently obvious, yet is, I imagine, less known, or more frequently overlooked, than might be expected, viz. that the results of medical practice depend much on the ages of the sick treated; and that, consequently, those medical institutions that receive the largest proportion of inmates between puberty and old age must, if tolerably administered, necessarily give the largest proportion of discharges, and least of deaths; while the results of treatment in such as, giving shelter to all sorts of cases, receive a larger proportion than do our general hospitals, of very young and of aged persons, must, however administered, present a relatively high mortality. Every one knows more or less of the privations and hardships of military life on actual service, that they far exceed any to which peaceable citizens are exposed; also, that the improvidence of the soldier is quite puerile; yet, on a total of nearly 340,000 cases admitted into the general and regimental hospitals in the peninsula, in the course of thirty months, ending June 20, 1814, the mortality was, Sir James Macgrigor informs us, but 18,513, or about 1 in 18·30; that is, more nearly two-thirds than one-half less than that of the Marylebone Infirmary for the past year, or 5·50 per cent. instead of 15 per cent.

In like manner as to the navy, from which, likewise, very young and aged persons are excluded, it appears from returns published by Sir G. Blane, that on a grand total of admissions, amounting to 106,631, the mortality was but 1 in 14·60, or about 7 per cent. Now there is no way of accounting for the bulk of the difference between the civil and military mortalities above stated,

but by referring to the known superior tenacity of life, and elasticity of health, of young or middle-aged adults, as compared with immature or decayed constitutions. I know no reason for supposing military medical officers more skilful than civil medical officers; and though they were more skilful, I know of no reason for believing that such superior skill would make much difference in the relative aggregate mortalities of civil and military practice. The waste of human life is notoriously owing principally to causes over which medical practitioners have professionally little if any control—to indolence or excessive labour, to gluttony or deficient nutriment, to atmospherical vicissitudes, to noxious effluvia, to mental depression, to peculiar predispositions to disease, natural or acquired, and to organic deterioration by lapse of years. And the utmost effect that could be reasonably expected from even an universal medicine, long established in general use, to imagine such a chimera for illustration's sake for a moment, would be, not the prolongation or restoration of youth at will, but the elevation of the average duration merely of life, to some threescore and ten, or perhaps fourscore, revolutions of the seasons. J. C.

Wimpole-Street,
March 1836.

FALLOPIAN TUBE PREGNANCY;

WITH THE POST-MORTEM APPEARANCES.

To the Editor of the Medical Gazette.

Sir,

The following case of Fallopian tube pregnancy is one affording many curious and mysterious points for consideration, and, I think, worthy of a place in your valuable periodical. It will not appear surprising the patient's sufferings were not ascertained during her life. Many circumstances arise in practice which makes it highly desirable for a professional man to give a correct diagnosis and prognosis of the nature of the malady under which his patient may be labouring. I was compelled, in the present instance, however unwillingly, to acknowledge my ignorance of the nature of the disease: I never before witnessed a similar complaint. This case clearly shows how necessary it is for medical men to be guarded in their opinions. I have purposely omitted the treatment, as it could not possibly be interesting, and confined myself to the history of the case. As there were several rumours afloat as to the cause of this young woman's death, after some little delay I obtained permission to examine her body. It was my opinion, from the commencement of her illness, that there was something unusual in it. In consequence of which opinion, I requested the presence of Dr. Turner during the post-mortem examination; and he witnessed every stage of the dissection.—I am, sir,

Your obedient servant,
William Robbs.

Grantham, Feb. 26, 1836.

Ann Wright, aged 21 years, of spare habit of body, had been labouring under cold for some days. On the 5th of February, 1836, she was much worse. The bowels were costive; she had considerable fever, and pain of the head. In the morning she had taken some antibilious pills, which did not operate. I ordered her a saline aperient, to be repeated frequently till the bowels were freely relieved. On the following day she was much better, but appeared low-spirited, and presented a dejected countenance. My attendance was hastily requested on the afternoon of the 9th. On my arrival, she was seated on a chair in her bedroom, crying out most violently with pain in her belly. As she was seated in a dark part of the room, I requested her to rise and walk to the window; this she declared herself unable to do, or even to stand upright. At this time her pulse was very small, frequent, and irregular. The surface of her skin was cold. She appeared writhing under the most agonizing pain. The bowels were costive, and she was harassed with frequent vomitings. The catamenia had been regular, and there existed no reason to suspect she was pregnant. I carefully examined the belly, supposing at first she was about to miscarry; the state of the abdomen from touch appeared natural, but rather flatulent. The pain was not increased on pressure. There existed great anxiety of countenance.

The next day she was greatly relieved from the pain of the belly. There was tenderness over the region of the sto-

mach, and she had been sick several times during the night. The bowels had not been evacuated; the pulse had become more full and regular; the tongue was covered with a cream-coloured fur. On examining the abdomen, it appeared rather larger than natural, but she experienced no inconvenience from pressure, except about the scrobiculis cordis. On the morning of the third day of the attack the bowels had been relieved, and she appeared much better. My attendance was requested at five o'clock in the morning of the 13th of February, the fifth day of the attack. She was lying on her back in bed, with the knees slightly drawn upwards, and crying out of violent pain of the stomach and lower part of the belly. The breathing was very rapid, and performed with great labour. On my asking her questions, she replied with difficulty. The pulse was feeble and irregular; the surface of the skin was cold, and bedewed with cold perspiration; the difficulty of breathing kept increasing, and she expired about nine o'clock.

I examined the body forty-eight hours after death. Nothing unusual was to be observed externally, except the abdomen appeared rather larger than natural. On inspection, the hymen was found wanting, and the os uteri appeared near the orifice of the vagina. I proceeded to open the cavity of the abdomen, it having been the seat of all her sufferings. On a division of the integuments, the stomach, liver, and omentum, were respectively brought into view: the former was distended with gas, and the latter appeared of a very dark colour. As the incision was continued, a large quantity of fluid and coagulated blood was made manifest. At this stage of the dissection, I removed two wash-hand basinfuls of blood, and then carefully sought from what source the hæmorrhage had taken place. I commenced my examination from the œsophageal extremity of the stomach, and continued it downwards to the pelvis. This latter cavity was filled with coagulated blood. On removing this, a tumor was observed, about the size of a moderate apple, situated in the neighbourhood of the right ovarium, and partially covered with coagula (some having been previously removed). By carefully stripping off the remaining coagula, I found the seat of the hæmorrhage. There was a rupture in the tumor previously observed, and in its centre was a perfect fœtus. Having proceeded thus far with the examination, I thought it advisable to remove the whole contents of the pelvis, for a more minute dissection. This was easily accomplished. The bladder and its ureters were in a natural condition. The body of the uterus was larger than is natural in the virgin state.

The ovarium on the right side was healthy, and presented several "vesiculæ Graafianæ," in a very mature state. The Fallopian tube on this side was pervious and natural. The ovarium on the left side was rather more than half the size of the right. It contained a vesicle, filled with about half a drachm of pellucid fluid. The other part was in a healthy state, and presented nothing unusual. The Fallopian tube on the left side was shorter than the opposite one; it appeared as if the fimbriated extremity had grasped the ovum, and the latter to have partly passed down the tube for about half an inch. The tumor, or impregnated ovum, had attained the size of a common apple. I distinctly exposed the fibres of the Fallopian tube, expanded over its surface. The parietes of the tumor in the neighbourhood of the rupture were very tender, and easily broke down under pressure. The contents of the ovum were a fœtus of about three or four months' gestation, umbilical cord, placenta, and its membranes. The blood-vessels in the parietes and adjacent parts were of large size, and very numerous. The tumor was attached to the ovarium by the medium of the peritoneum. I endeavoured to inflate the Fallopian tube, from the part expanded over the ovum to the womb; at first I thought I had succeeded, but, on a more careful examination, it was found to be the peritoneum. I now opened the cavity of the uterus, and this appeared more capacious than it would have been in a natural state. It contained a membranous substance of a mucous character, which, however, did not line the whole internal surface. The mouth of the womb was open, and the internal surface was highly vascular. I now endeavoured to inflate the Fallopian tube from its uterine extremity; but this I was unable to accomplish, owing to a complete obliteration of the passage of the tube for more than an inch. A most careful dissection of this part took place, and

there did not exist the slightest passage (for an inch) from the uterus to the fimbriated extremity. The tube at this part appeared very solid, and of a distinctly fibrous character; and in fact there seemed to be no remains of a passage having ever existed at this particular part.

Observations.—The foregoing case is one highly interesting in a physiological point of view. From the appearance of the affected Fallopian tube, I should be induced to believe the obstruction was of no recent date, there being no signs of any inflammation or other disease having affected it, or the adjacent parts. But did this obstruction exist before pregnancy had taken place? I am inclined to think it did. And if the Fallopian tube on the impregnated side were impervious, how was fecundation effected? I believe this woman had advanced twelve or fourteen weeks in her pregnancy; and consequently there had been sufficient time for adhesion of the lining membrane of the tube to have taken place subsequent to impregnation. It would be highly interesting, therefore, to know how long a time elapses after a fruitful coition, and the reception of the impregnated ovum into the body of the uterus. It appears improbable that inflammation of the lining membrane, or thickening of the parietes of the tube, should have been so immediate and severe as to have prevented the descent of the ovum. Dr. Blundell has made many interesting experiments, which go to prove that impregnation cannot take place, without the semen come in contact with the rudiments, and he therefore considers, when the ovum lodges either in the Fallopian tube, the peritoneal cavity, or in the ovarium itself, and is there impregnated, that the semen must be conveyed to these parts. If Dr. Blundell's theory is correct, it would appear impossible for fecundation to have been effected subsequent to the obliteration of the tube; and therefore that it was consequent on the changes which take place during coition. This appears to be the more probable supposition, and that my opinion of the disease of the tube having pre-existed, was incorrect; but I came to the conclusion from the appearance of the part on a minute dissection.

I am fully aware there are a variety of opinions as to the manner in which fecundation is effected. Dr. Davis, in his excellent work on Obstetric Medicine, gives us the following theory, and which appears very plausible. "I hold it most probable that, in the first place, a definite time is required for the various fluids of each sex, which seem to be emitted into the cavity of the uterus after a fruitful intercourse, to be more intimately admingled, and brought into a state of mutual agency. When the period of this preparation is complete, the mature and intimately blended fluids become animated by the nisus formativus, by which the hitherto unformed materials of generation are partly moulded into the elegant coverings of the ovum, and partly into the figure of the contained embryo." From this it appears Davis considers that a certain time is required for the admixture of different fluids in the body of the uterus. Is it not probable in the present instance, that a certain time elapsed for this preparation to take place, not in the body of the uterus, but in the ovarium itself; and during which period a change might have taken place so as to prevent the natural descent of the impregnated ovum? If such were the case, we can easily imagine, from the ovum increasing in size, that the parietes of the tube would become thickened, and the passage liable to be obliterated.

TWO CASES

OF

HYDROCEPHALUS.

To the Editor of the Medical Gazette.

Sir,

If you think the two following cases worthy of publication in your Gazette, I shall be obliged by your inserting them at your convenience. I give them to you as copied from my case-book.

I am, sir,
Your obedient servant,
T. Marsh,
Surgeon, &c.

Coleford, Forest of Dean,
Gloucester, March 7, 1836.

The infant (aged about ten months) of a poor woman named Beach, residing in the Forest, was placed under my

care, in the Dispensary, some time ago, suffering from hydrocephalus. The mother told me she had had a very severe labour; her child's head was unusually large when born, and had been increasing in size ever since. Upon examination I found the head considerably enlarged, the fontanelles widely extended, pupils dilated, oppressed pulse, great drowsiness, but sleep disturbed, coldness of the feet, and evident dimness of sight; added to these symptoms the pulsation at the temporal arteries was strong, though slow; and if I might judge from that, and the pain which I produced by raising or moving the head to either side, the meninges of the encephalon, as well as the brain itself, was in a state of high inflammation. Though it appeared a hopeless case, I could not abandon hope whilst life remained, and recollecting the maxim of Celsus,

"Satius est anceps auxilium quam nullum,"

I proposed to the parents, as a last resort, and the only one likely to be beneficial, to suffer me to perform the operation of paracentesis. After some hesitation they consented.

I performed the operation in the common way, cutting through the integuments with a knife, and then evacuating the fluid (which had evidently accumulated upon the surface of the brain, although very probably there was a small quantity in the ventricles) with a trocar. The fluid was straw-coloured, and measured about twenty-four ounces. Immediately after the operation I bandaged the head as firmly as circumstances admitted, and, as quickly as I could, applied the ung. hydriod. potassæ; kept the bowels regular with calomel and mild aperients, and though the little sufferer was some time in a precarious state, he did recover, and is now a very fine boy, never having had the slightest return of the complaint.

Case II.—The latter end of the year 1834, I was called to the wife of Humphry Lugg, (one of the men belonging to Messrs. Pearce and Allamay's tin-works, at Lydbrook-in-the-Forest). I visited her immediately, and found she was in labour of her sixth child; the pains natural, and common presentation, the head first engaging with the pelvis. For 12 or 15 hours the pains were very violent, and produced little effect: anticipating a case of great difficulty, and my patient at best an invalid, I sent her husband to Coleford, about 5 miles distant, for the instruments; before he returned, however, nature *(the safest of accoucheurs)* had accomplished the work. The infant was apparently dead, but as there was evident pulsation in the funis, I used the warm bath, &c., and the child recovered. Its head, which at the birth was unnaturally large, rapidly increased in size; and as the parents strenuously opposed any operation, all remedies were tried, and all failed; the poor child lingered in a most distressing state *ten months* and four days. For the last four months of its life, the measurement varied but little from the following, which I took in the presence of a grandson of the late justly distinguished Mr. Hey, of Leeds.

From radix nasi to protuberantia occipitalis, 26 inches; fronto-occipital circumference, 32 inches; from ear to ear, across the vertex, 24 inches; round the chin, and across the vertex, 30 inches; length of corpse, 19 inches; circumference of neck, $4\frac{1}{2}$ inches; fluid, 154 ounces.

The friends would not permit the slightest post-mortem examination, only allowing the evacuation of the fluid by the trocar. The bones of the skull seemed to be obliterated; and I have little doubt, if the child had lived another week, the integuments would have given way.

Having given you these cases, may I ask the following question:—Why are the optic nerves commonly relaxed in hydrocephalus? does it depend upon an increased quantity of fluid in the ventricles, or arise from some interruption to the natural functions of the brain?

ATMOSPHERIC INFLUENCE IN THE PRODUCTION AND MODIFICATION OF DISEASE.

To the Editor of the Medical Gazette.

Sir,

In this variable climate of ours, every one is constantly talking of the weather, and of its influence over the healthful functions of the human body; and so

far as the changes of temperature are concerned, every body is agreed in ascribing a due portion of complaint to atmospheric influence. It is also generally admitted, that the changes of season, also the extremes of heat and cold, of moisture and of dryness, are productive of diseased action in the human system; and also that marshy situations alter the condition of the atmosphere, producing marsh miasm or malaria, and generating diseases, varying according to the country or climate in which they occur. These instances of atmospheric influence are obvious, and such as can be recognized by the senses, or proved to a demonstration; but I apprehend there are other changes taking place in the atmosphere, productive of not less important results than those already enumerated, but of so subtile a nature as to be wholly impalpable to our senses, and which are only to be recognized from certain effects being produced, which can only be accounted for by their agency—such. for example, as the simultaneous appearance of some disease over a large district or a whole kingdom, as in the instance of influenza extending over great part of Europe at one and the same time. Another example I may mention, on a more limited scale, was the appearance of puerperal fever, in the year 1812, in all parts of the counties of Northumberland and Durham; and every medical man must have witnessed the sudden out-breaking of continued fever, or of small-pox, measles, or scarlet fever, where none existed before; and if further evidence is wanting, I would just remind my medical brethren how often it happens, when we meet with one case of any disease not of a contagious nature, how generally it is followed by several similar ones. I have repeatedly known several cases of apoplexy or of abortion occur in quick succession, and after a little time the tendency to these has passed away for an indefinite period.

Atmospheric influence does not appear to be confined alone to the production of disease, but it seems also to modify the type of a disease already established. Of this I will state an instance. In the winter of 1818—19, typhus fever prevailed in this district to a great extent; the treatment found to be the most successful was bleeding and mercury, together with purgatives and diaphoretics. It diminished during the summer, but increased again in the succeeding winter: but its character was changed; it would no longer bear depletion: bark, wine, and ammonia, were the appropriate remedies. Every practitioner of a few years' standing must have witnessed similar instances, where diseases have occurred, in which the ordinary remedies were either altogether inapplicable, or where it became necessary to employ them with great circumspection. This was remarkably the case after the invasion of cholera. Even in cases of acute inflammation it became necessary to bleed with great caution; and the same held good with regard to purgative medicines. Nor can it have escaped observation, that periods occur in which there is a greater tendency for complaints in general to terminate fatally than at other times, many deaths occurring within a short space of time.

If I have succeeded in proving the probability of atmospheric influence being the proximate cause in the production and modification of disease, and that certain states and conditions of the atmosphere favour the development of certain diseases, it would then appear that the germs of these diseases are always present, but in a latent state, until such atmospheric changes occur as call them into activity. If this is admitted, and I see no reason to doubt it, it then becomes a matter of grave importance to inquire what is the nature of these conditions of the atmosphere which give activity to individual diseases. It is a subject of somewhat difficult investigation, but I think much useful information might be gained were every medical man to observe and record the weather and temperature, the moistness or dryness of the atmosphere, in connexion with prevailing diseases, and the mode of treatment he found the most successful. In this way such a mass of medical statistics would gradually be acquired, as might ultimately produce very important results in the knowledge and treatment of disease.

I am, sir,
Your obedient servant,
EDWARD GREENHOW, M.D.

North Shields, March 12, 1836.

MEDICAL INSTITUTIONS OF GERMANY.

BAVARIA — MUNICH.

To the Editor of the Medical Gazette.

SIR,

I BEG to forward you some further particulars respecting the Bavarian medical institutions, which may interest many of your readers.

The hospital at Munich is one of the best I have seen on the Continent. Its interior organization might serve as a model. It was erected in 1813, and occupies a quadrangle, which encloses two large court-yards. The wards (fifty-four in number) are of the same size, each containing ten or twelve beds; they are extremely clean and well ventilated, and are paved with square pieces of marble; as are also the spacious corridors into which they open. Between every two wards is a small apartment, containing every thing required in ordinary use, and a plentiful supply of warm and cold water. They are all kept at the same degree of temperature, by an apparatus for heating air at the top of the building. The operating theatre is commodious, well lighted, and supplied with bandages and dressings of all kinds, ready for immediate use. The baths are convenient and in good order, though baths are much less frequently prescribed in Germany than in France. The office of nurses is performed, both in the male and female wards, by fifty *sœurs de la charité;* as is also the case in the Austrian dominions. There are two physicians and a surgeon, who visit the patients every morning before nine o'clock. There is also a physician who has the exclusive charge of the syphilitic patients; seven or eight assistants accompany by turns the principals in these rounds: three of these reside in the house for two years, and receive 300 florins annually. The four principal medical attendants receive about 600 florins each per annum. Besides the public wards, to which all are admitted on application, there are—a ward for students of the University and of the Academy of Arts; a male and female ward for persons of the Jewish religion; and about twenty rooms, neatly furnished, for the accommodation of as many patients, each of whom pays a florin a day, and has the exclusive attendance of a nurse.

Syphilitic patients, those with psora, and other cutaneous diseases, and those with diseases of the eyes, have separate wards appropriated to them. The ophthalmic wards are four in number, each containing six beds: attached to this department is a small theatre, where all operations on the eyes are performed.

The hospital is supported, like most others in Germany, by contributions from the town, and a trifling tax on servants and others of the inferior classes. The number of patients in the house generally averages about three hundred. There are no out-patients. Those who die are examined in the new anatomical building erected a short distance from the hospital. The amphitheatre, for anatomical lectures and demonstration, is commodious, and capable of containing 300 spectators. The dissecting-rooms are also convenient and clean. This building contains the pathological museum, which is small, but possesses some valuable preparations. Pupils dissect here with much more care and neatness than I have observed elsewhere on the Continent.

Munich also contains military hospitals; a madhouse (which is in very bad order, and can only be considered as a place of detention); a foundling hospital, and *maison d'accouchemens.* This latter has about sixty beds; of which one-half are for pregnant women, who are obliged to work at spinning, knitting, &c. five or six hours a day. Women are allowed to remain nine days after their delivery, and are obliged to take their infant away with them. The wards of this building are low and indifferently ventilated; too many beds being placed in one apartment. In the clinical ward, lectures are delivered by the professor of obstetricy of the University, and accouchements take place. Midwives attend labours in all ordinary cases. About fifty women are annually instructed in midwifery, and are obliged to undergo an examination before obtaining a license to practise. Between four and five hundred women are annually delivered in the hospital. Inflammation, and other unpleasant consequences, are said to occur but rarely, and the mortality is exceedingly small.

The University has not been established many years, but already ranks high as a school of medicine, several of

the professors being persons of the highest reputation and attainments. The number of students formerly amounted to 2000; but owing principally to political circumstances, and the restrictions imposed upon the admission of foreigners, there are at present not more than 1200, of which about one-third follow the medical classes. There is no fixed order of study, and the examinations are much less rigid than at most other universities, although diplomas are never granted to foreigners without examination, for which a candidate may present himself after three years' study. At the expiration of this period, the student undergoes the examination termed *rigorosum*, which consists in written and verbal questions and answers, and the performance of a surgical operation before the examiners, who are professors at the University. The subjects of this examination are anatomy, pharmacology, general and special therapeutics, surgery, and midwifery. The candidate is also required to write and defend a thesis, and to publish a Latin dissertation; after which, if approved, he receives the diploma of Doctor of Medicine or Surgery; which, however, does not authorize him to practise until he have passed two other examinations. The first of these takes place two years after the *rigorosum*; during which time the candidate may travel to other countries, or practise under the direction of an established physician. This examination, termed the *probe-relation*, is held before a committee of professors, and also consists of verbal questions and written propositions, with the performance of any operation selected by the examiners. The last examination takes place in October of every year, at which period from forty to sixty candidates present themselves; five questions are proposed, to which written answers are made, and, according to the manner in which the candidate acquits himself, is he placed in the first, second, or third class of practitioners. The first class practise in Munich, or in some other principal town of Bavaria. The second class are mostly restricted to country practice; and the third to thinly-populated districts, or, if in towns, to the management of the slighter cases of disease. The expense of attendance on lectures, and examination fees, amounts to about 500 florins, including the preparatory studies on physic, chemistry, natural history, botany, and mineralogy. The professors most highly estimated, are the well-known Walther, who fills the chair of clinical surgery and ophthalmology; Döllinger, professor of anatomy and physiology; Ringseis, medical clinique; Buchner, pharmacy and materia medica; Weissbrod, midwifery; Vogel, chemistry.

Should you think these communications worth inserting in the Gazette, I will, in my next, transmit a sketch of the state of medical and surgical practice.

EDWIN LEE.

Munich, March 2, 1836.

GALEN, ON FEIGNED DISEASES.

"HOW TO DETECT THOSE WHO FEIGN DISEASE."

[THE following translation of Galen's tract—Πῶς δεῖ ἐξελέγχειν τοὺς προσποιουμένους νοσεῖν—is, we believe, the first that has ever been made in English. Nor are we aware of any other modern version of it, except one in German, by Metzger, published in Pyl's Repertorium. It is the oldest treatise extant, expressly devoted to a medico-legal subject; and, taking into account the period at which it was written, will probably to many appear, however imperfect, sufficiently curious and interesting. The author, it will be recollected, flourished in the second century of our era *.]

Persons feign illness for many reasons. Now, in all such cases, the discovery of the truth seems to be of the physician's province, although ordinary individuals often fancy themselves competent to the task. To the medical practitioner, certainly, it belongs to distinguish and discriminate that sort of phlegmon, erysipelas, and swelling, which are

* The present is not the only subject connected with legal medicine that Galen has treated, or at least touched upon. In his celebrated work, *De Usu Partium*, he has pointed out the peculiarities of the heart and lungs of the fœtus, which serve to distinguish them from those of the child that has breathed and lived for a time. But, as compared with other parts of medical science, he has said so little on medico-legal matters, that his very silence is significant. That so great a master of the learning of his age, and who wrote so much, should have never once alluded to the importance of medicine as applicable to the proper administration of justice, is fatal to the supposition of those who labour to prove the antiquity of legal medicine.

purposely produced by external applications, from those which have their origin in the complaints of the body itself; also, to mark the difference between blood spat from the interior of the mouth, and that which originates in the œsophagus, stomach, or organs of respiration: for persons have been detected who had the power, whenever they pleased, towards the end of a cough, to spit blood—some small vein about the gums being conveniently ruptured for the purpose, and kept in readiness, so that at pleasure, by sucking it with the tongue, blood was discharged upon coughing, as if it came from the chest or abdomen.

Again: individuals have pretended madness and folly, while they have been only making fools of other people. It is in cases of this kind that medical men are generally allowed to be the fittest persons to ascertain the truth.

It often happens that where a malady is feigned, intolerable suffering is pretended. I once knew a man who, on being summoned to a public assembly which he did not like to attend, simulated a painful colic. I suspected at the time that he was feigning, in order to escape the meeting; and he afterwards confessed to me that such was the fact. I ordered him fomentations; but he was not very anxious for assistance, though at other times the least illness used to alarm him. He was aware, besides, that only a few days before, I had speedily relieved a patient from colic by a dose of *philonium**: a medicine which he certainly would have asked for, had he really been in agony. But the event showed the nature of the case: as soon as the public meeting was over, the complaint ceased—there was no longer any pain. The mode in which this person lived previously was also calculated to throw light on the circumstances: his diet was not of a kind to produce colic; for disorders of this description usually arise from indigestion and chills (ψύξεων), neither of which had happened in the present instance. It was therefore a matter for medical experience to decide (taking into account the manner of living which had been antecedently practised) that there was here no real disease. The suspicion that the business of the meeting might lead to some trick, I by no means claim as owing to *medical* sagacity; it was the mere exercise of that *reason* which is said to be common to all, though few have it in so practised and perfect a state as to be ready on every emergency for what is best to be said and done. Let it accordingly be remembered, that if, along with our medical experience, we possess this intellectual power, we have the means of detecting many similar and gross deceptions.

A case of the latter kind occurred to myself. The pretending sufferer was a slave, of that class who have to perform journeys on foot, running by their masters' side. He complained of excruciating pain in both his knees. I immediately suspected a trick, as his master was to set out on a journey that day, and I was aware that the young man was not very honest, or scrupulous about the truth, in matters of this description. Besides, I inquired of a fellow-slave of his, who knew him intimately, whether the patient was not amorously attached to some female, on whose account he was desirous not to leave home, when his master was about to travel a considerable distance? And this proved to be the fact: so that here was detection by extraneous means (ἔξωθεν). But one of the knees was immoderately swollen, so as easily to alarm a non-professional person: the eye of experience, however, could see that all the ailment present was caused by the application of *thapsia**. And

* This was a famous electuary of the opiate kind. It was called Philo's antidote, after Philo, of Tarsus, its inventor, who lived, it is supposed, in Augustus's time. The composition of the Philonium, described in Greek elegiac verses, is preserved and explained by Galen, *De med. comp. sec. loc.* lib. ix. 4. The terms of the recipe are enigmatical, and may amuse some readers; we give the substance:—"Take of the yellow and fragrant hair of the divine Crocus, whose blood glitters in the fields of Mercury, as many drachms as a man has senses; of the Eubœan Nauplian, a drachm; of the slayer of Menœtiades, as preserved in the bowels of sheep, the like quantity; add twenty drachms of white flame, and twenty of the bean of the wild animal of Arcadia; a drachm of the root (falsely so called) which grows in the land famous for the Pisæan Jove; take twice five drachms of πιὸν, written with the masculine article prefixed; and mingle all with the production of the daughters of the bulls of Athens." Galen interprets this curious medico-poetical farrago, which without his aid would certainly be not a little obscure, as implying the admixture of saffron, pyrethrum, euphorbium, white pepper, hyoscyamus, spikenard, opium, and Athenian honey. It is, moreover, stated in the verses, that the pains for which this μέγα εὕρεμα was most serviceable were those of colic, of the liver, dysuria, and stone.

* Pliny, copying Dioscorides, mentions *thapsia* as a species of *ferula*: see his account of the virtues of the plant, which he conceives to be virulently poisonous, and to be meddled with

here was detection peculiar to *medical* sagacity; to which it also belonged to decide that nothing had previously happened capable of raising such a tumor so suddenly; for the person had not run of late to any excess, nor had he been beaten by any one; nor had he been dancing; nor in jumping over any ditch had he hurt himself; neither did he exhibit any appearance of too full a habit, for he had not lived either luxuriously or intemperately previously. Further, when I came to question him concerning the sort of pain he felt, he neither answered promptly nor consistently. His master being now gone, I administered an application which had no efficacy whatever in the allaying of pain, but simply the virtue of cooling the quality of *thapsia*. In the course of an hour he confessed that the pain was gone. Yet, had his suffering been caused by real phlegmon, so far from being relieved by the cooling remedy I gave him, he would have been only rendered worse.

Thus it is evident, that if medical skill be combined with ordinary sagacity, the reality or groundlessness of alleged pain may be precisely determined.

But from the very manner itself in which the malady is endured, a judgment may sometimes be formed that the pain cannot be very severe; for those who really suffer under a painful affection are almost invariably agitated in divers ways, according to the severity of the ailment,—a thing which those who practise deception do not take sufficient care to observe. Those also who labour under excruciating pain are ready to adopt any means of relief; they even exhort their medical attendants to do whatever may seem best to them for the cure of their disorder. But persons who only suffer a little, or none at all, carefully eschew all such aid, not being particularly fond of low diet or active treatment; and we should do well probably to tell them, that for such complaints as they say they labour under, there can be nothing better than scarifications, the cautery, and abstinence from drink and food of the very sort to which they are known to be most attached.

There are other medical observations, connected with actual pain of a severe nature, which may serve to detect impostors,—such as exhaustion, coldness of the extremities, paleness, sometimes cold perspirations, and the irregularity of the pulse (which, indeed, happens even to those who suffer very little pain), the pulse being often more frequent in moderate than in severe suffering, and under obscure than strongly-marked symptoms.

Further, when a feigner is asked about the kind of pain he feels, he always describes it as settled in the part which he says is affected; whereas, it is to be borne in mind, that this is not invariably the case with respect to really severe pains, some of them being felt extensively over the adjoining parts, while others are fixed and confined to a particular locality: some, for example, throb as if struck with blows; others seem to tear the parts asunder; others are of a benumbing quality; others bear down; while others, in fine, are attended with vomiting, disturbance of the belly, and obscurity of vision*.

only with great caution, Hist. Nat. lib. xiii. c. 43. Matthiolus gives a good figure of the thapsia of Dioscorides; it is one of the *umbelliferæ*, and its English synonym (acc. Loudon) *deadly carrot*. Hippocrates employed thapsia, in the shape of a very diluted extract, as an emetic; in the treatment of diarrhœa, he gave the leaves with honey; and externally, mixed with cerate, the root of thapsia was used as a discutient—for the removal of ecchymoses.—*Dierbach: Arzneim. des Hippoc.* The irritating or inflammatory quality of thapsia is well known to the people of the southern shores of the Mediterranean at the present day. Poiret, in his *Voyage en Barbarie* (t. ii. p. 138), mentions that he saw an Arab rub his cheek with *thapsia* (*T. villosa*) for the cure of ringworm: the part became swollen in a few hours, and was greatly inflamed. Dierbach thinks that the thapsia of the ancients was *T. garganica*, a native of Calabria, the north of Africa, and Greece: Sprengel, however, calls it *T. asclepium*, L.

* It deserves to be added, that the five general rules laid down by Zacchias for the detection of feigned diseases, and which, as Dr. Beck says, "are so discriminating as to have received the sanction of most succeeding writers," are all deduced from the principles contained in the above tract. Dr. Beck, in giving an abstract of the rules, commends them, on the score of "the universality of their application, and the ingenuity of their author." Galen, however, and not Zacchias, seems to have the best right to be accounted their author; for Zacchias himself says, in introducing them, "*Ego illius auctoris* (meaning the author of the tract) *doctrina munitus, et rationabili discursu adjutus, dicendum censeo, quod quinque potissimum ingeniis deprehendi possint ii, qui morbum aliquem se pati simulant,*" &c.: and the reader will at once perceive, on considering the rules in question, that they are all illustrated in Galen's treatise, as given above. Their heads are briefly these:—1. To look to the possible motives of the suspected party; 2. To the likelihood of the alleged disorder—taking into account the patient's previous habits and mode of life; 3. The disposition to be relieved; 4. The consistency of the attendant symptoms; and, 5. That of the consecutive or secondary symptoms.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue a abréger."—D'ALEMBERT.

On the Analysis of the Blood and Urine, in Health and Disease; with Directions for the Analysis of Urinary Calculi. By G. O REES.

THERE is probably no source whence pathological discovery is more likely to flow than animal chemistry. The field it presents was long comparatively neglected, but now begins to attract a larger share of attention. In this country we have hitherto been mainly indebted to Dr. Prout, who has united the characters, too seldom found together, of chemist and practitioner; but within a very recent period several others have appeared in the same department, and with every prospect of advantage to themselves and to the profession. It was but in our last number that we inserted the concluding portion of an elaborate and very valuable history of urinary deposits, by Mr. Brett, with whose attainments as a chemist the readers of this journal have been for some time familiar. Another claimant to attention is before us in Mr. Rees, and we can safely recommend his present volume, as calculated, by its perspicuity, simplicity, and accuracy, greatly to facilitate an acquaintance with the more important practical parts of animal chemistry. The methods of performing both quantitative and qualitative analyses of the blood and urine are described in a manner, which even the uninitiated cannot fail to understand, while the processes are economical, and require patience rather than skill in conducting them.

The detection of foreign principles in the urine has received much more attention than as regards the blood, yet no greater difficulty attends the examination, and we can scarcely hesitate to admit that their detection, while still poisoning the frame by their presence in the circulating mass, must be of very great importance to practical medicine. On this point Mr. Rees makes some judicious observations, and points out, that the medical profession has, till very lately, devoted so little attention to the analysis of the blood, that we have but few observations of value regarding its diseased condition. This may account for the fact, that as yet our practical improvements have not kept pace with our increasing knowledge of pathological chemistry. It is to be hoped, however, that as more physicians than heretofore become practical chemists, this will cease to be the case.

The most interesting change with respect to the blood is where it contains principles which belong to the secretions, but which, from some morbid cause, cease to be eliminated: the most remarkable of these are urea, the colouring matter of the bile, and cholesterine. We extract Mr. Rees' account of the methods of detecting these; by which it will be seen how true is the remark which he makes with respect to the fact of care and patience being the chief requisites in conducting the necessary manipulations:—

"*Examination of Blood supposed to contain Urea.*

1. Let a portion of serum destined for analysis be accurately weighed, and then evaporated to dryness over an open steam-bath.

2. A quantity of distilled water (amounting to about one ounce for each 200 grains of serum used for experiment) is to be heated to 200° Fahrenheit, and then poured on the dry extract, which must be previously broken up with a sharp spatula.

A digestion over the steam-bath for about half an hour is now to be performed; the loss of water by evaporation being supplied occasionally by the experimenter.

3. The digested fluid is to be filtered, and the residue on the filter washed with distilled water (the washings being added to the original liquor). The whole of the filtered liquor is now to be evaporated to dryness over an open steam-bath, and the residue of the evaporation digested, with a considerable proportion* of absolute alcohol, at a gentle heat, for half an hour; care being taken that the loss by evaporation do not materially diminish the bulk of the fluid.

4. A second filtration is now to be performed, and the filtered fluid must again be evaporated to dryness, and then dissolved in a small portion of lukewarm distilled water. We thus

* About eight times the bulk of the solid extract for digestion.

procure an aqueous solution of urea, combined with animal extractive; to this solution (previously evaporated to the consistence of a thin syrup) we now add a few drops of nitric acid, which causes an effervescence. This mixture must be set aside to crystallise.

5. Should crystals appear, of the peculiarly characteristic appearance of nitrate of urea, we may conclude that urea is present: indeed, if crystals exist at all after the foregoing process, they must be nitrate of urea; since no principle of the blood that can possibly exist in the last-tested fluid possesses the property of becoming less soluble by the addition of nitric acid.

6. Crystals being formed in the liquor*, we may now proceed to ascertain the proportion of urea. For this purpose we must first allow some time to elapse, in order that the deposition of crystals may be perfectly accomplished.† When such is the case, the supernatant liquor must be poured off; which, with the assistance of a small glass rod (to retain any very minute crystals) may be perfectly effected. The acid crystals remaining are now to be carefully dried over the open steam-bath, and then weighed; from their weight we may infer the proportion of urea present, since we know the composition of nitrate of urea to be—

Urea	52·63
Nitric acid	47·37
	100·00

If it be required to ascertain the relative proportion of each other ingredient of blood containing urea, it will be right to make a separate analysis for that purpose; since the use of the open steam-bath and distilled water at 200° Fahrenheit will materially interfere with the determination of the quantity of albumen. I feel convinced that the wish to ascertain all by a single analysis has frequently been the cause of failing in the detection of urea when it existed in the blood.

Examination of Blood containing Colouring Matter of Bile.

The best account which has yet been given of this diseased condition of serum is by Lecanu, who satisfactorily proves that in jaundice the vital current is strongly impregnated with those matters, that in the healthy state are peculiar to the secretion of the liver. This able chemist has established, that in cases of jaundice, the blood contains the following principles, foreign to its healthy constitution:—

1. A combination of albumen and soda, scarcely at all soluble in water.

2. An orange-yellow colouring principle.

3. A blue colouring principle.

These colouring principles have been demonstrated to exist in the bile by M. Chevreul.

The examination of the serum of icteric blood is performed as follows:—

The serum is diluted with a considerable excess of alcohol, which renders it turbid, and precipitates a quantity of flocculi. These are collected on a filter, and washed repeatedly with cold alcohol. This filtered alcoholic solution is of a yellow colour, and possesses an alkaline reaction; it yields a dark yellow-coloured residue on evaporation, which has a saltish disagreeable taste. It is deliquescent, and almost entirely soluble in ether. The portion insoluble in the last-named menstruum is granular, and of a salt taste, without bitterness. It contains, besides salts, an extractive matter, soluble in alcohol, and another organic matter, such as is met with in healthy blood.

The ethereal solution is now left to spontaneous evaporation, when a considerable orange-yellow residue is obtained, which contains crystals of the crystalline fatty matter of the blood. These crystals may be separated by warm alcohol, which also extracts an oily matter, of a beautiful deep yellow colour.*

The albumen which has been precipitated is now to be treated with boiling alcohol, which assumes a dark green tint, and by cooling deposits crystals of fatty matter. The liquor, when cold, is to be filtered, and then evaporated over a water-bath. During the evaporation, it retains its original tint for some time; but when the alcohol is nearly dissipated, the green colour disappears, and a yellow tint is observable, while at the

* It will always be observed, in specimens where urea exists, that, long before any material diminution occurs in the bulk of the fluid (which has been mixed with nitric acid), a crop of crystals appears.

† This must be determined by the discretion of the operator, as it is impossible to lay down rules on such a subject.

* This has been lately shown by Braconnot to consist of the yellow matter of bile in combination with an oily matter.

same time a portion of brownish matter deposits on the sides of the vessel. This brown deposit may be washed with cold alcohol, to free it from the other matters; when it will be found very soluble in boiling alcohol, and capable of producing a fine blue colour when dissolved in that liquid. It is remarkable that exposure to the rays of the sun destroys this colour.

The yellow serum of jaundice may be very easily tested for bile by the addition of dilute sulphuric acid, which is capable of changing the colour to a delicate green after the lapse of a few minutes. This is a very simple method, and no less easy than it is satisfactory, and void of fallacy.

The jaundiced serum is thus described by Lecanu:—It possesses a sickly taste; it is of a saffron colour, which passes to a canary yellow on being diluted with water; it froths by agitation, and turns syrup of violets to a fine green colour.

Examination of Blood containing Cholesterine.

This principle is very easily discovered when it exists in blood; and many instances are on record, in which it has been detected in icteric serum. The late researches of P. S. Denis have convinced him that cholesterine is not a constituent of healthy blood; and it is on the faith of his observations that I class it as a substance foreign to the normal constitution of serum. I am at present engaged in a series of observations on the fatty matter of the blood, which will bear strongly on this subject, and I hope to be able to communicate the results in the Appendix. When serum is suspected to contain cholesterine, it should first be evaporated to dryness over a water-bath, and the dry residue must be digested with ether for several hours. The ethereal solution may now be decanted, and allowed to evaporate spontaneously. The residue consists of the fatty matters of blood combined with cholesterine.

These are to be well washed with cold alcohol, which extracts the oily matter of the blood, leaving the crystalline fatty matter and cholesterine. This latter may now be removed with the point of a penknife, or any fine instrument, as its crystals are very obvious and easily distinguishable."

In making these extracts regarding the blood, and in directing attention more particularly to this portion of Mr. Rees' volume, we by no means intend to imply that his account of the urine is not equally good; but having recently devoted so much space to the chemical history of the latter fluid, we are desirous of giving variety to our pages; and, indeed, by adding the methods of detecting the chief morbid ingredients presented by the blood to the processes applicable to the urine, contained in some former numbers, we give our readers, within the compass of the present volume, a little manual of animal chemistry, which we think they will find of considerable value.

Elements of Medical Jurisprudence. By THEODRIC R. BECK, M.D. Professor of the Institutes of Medicine, &c.; and JOHN B. BECK, M.D. Professor of Materia Medica, &c. Fifth Edition. pp. 1010.

THE merits of this work are so well known, that we need only mention what has been done for it by the authors in preparing the new edition. Chapters have been introduced on Policies of Life Assurance, and on Medical Evidence; the excellent tract on Infanticide, by Dr. J. Beck, has been still further improved and extended; Mental Alienation has been materially revised; and the whole subject of Poisoning has been remodelled. Christison's classification of the poisons has been adopted, and thus has one of the greatest objections to the book, as it previously stood, been removed.

The pains taken in bringing the work into its present shape—*au niveau*, as it is, with the best medico-legal information of the day—must have been prodigious: a large portion of it has been re-written, and the additions throughout, from almost every available source, are at once interesting and highly valuable.

We commend the zeal and conscienciousness of the authors, in scrupulously referring to the works (and the number of those works is amazingly great) from which they have drawn contributions: in this respect, they strongly contrast with the "compiling" pirate, whose catchpenny we noticed the week before last. In short, Beck's Medical Jurisprudence, in its present enlarged form, has been rendered quite an Encyclopædia on the subject: it is an admirable book of reference, and ought to be in the hands of every member of the profession.

MEDICAL GAZETTE.
Saturday, March 19, 1836.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."
CICERO.

THE METROPOLITAN UNIVERSITY ARRANGEMENTS.

THE rumours which are abroad respecting the appointments, said to be in contemplation, for the new University, are any thing but calculated to satisfy the professional public. What the Government really mean to do, we do not profess to know: the rumours to which we allude *may* be true; and on that ground it is that we venture to make a few observations.

The appointments which are matter of concern to all well-wishers of the projected establishment, are not those of chancellor, vice-chancellor, or any merely honorary functionaries: but those of the acting men—the personages who are to constitute the Board of Examiners, and on whose merits and respectability will depend the reputation —the success—of the whole scheme. Let us suppose, for an instant, a possible case: that the Government may be misled by the counsels of selfish and interested advisers, and in consequence are induced to nominate parties but ill qualified for the duties devolved upon them, and whose names are scarcely known to the profession at home—wholly *un*known to the medical world abroad: what may be the effect? Every one must be convinced that the whole undertaking — the long-desired consummation of founding a Metropolitan University—must, under such circumstances, prove a complete failure. Instead of possessing a great institution in London, in connexion with which would be found the names of men most illustrious for their professional merits, we should have a lumbering establishment with amateur physicians—persons never distinguished as practitioners, lecturers, or men of science — for its board of management. The result must be disastrous—the fair fame and utility of such a university will, by such a course, be smothered in the birth. Who ever cares for the honours (so called) of a university that has no great names attached to it — no truly eminent men among its conductors?

But it may be said that the choice is difficult, and that it will be hard to make the appointments at the outset, so as to please every body. Now, this we take to be the very reason why nothing should be done precipitately: at the same time that we deny the difficulty to be of a formidable nature. To be sure, if the line be permitted to be drawn by the parties already alluded to, and that they, in their short-sighted selfishness, so draw it as to exclude all others, beside themselves and a congenial few, from the executive of the establishment, it will, indeed, be difficult to rectify this unlucky stumble on the threshold. The doom of the new University will be sealed; and none of those who *might* retrieve its fortunes, fallen almost ere risen, will be willing to venture on such a forlorn hope.

We have heard with some feelings of surprise, of a deputation (consisting of three or four individuals), which lately waited on the Chancellor of the Exchequer, and the object of which was to persuade that gentleman, that in the new arrangements no person should be appointed an examiner who had any connexion with any school or hospital. Was ever known such egregious folly—if, indeed, it may not be characterised by a less reputable epithet! We wish the sapient members of this deputation would favour us with half a dozen—nay, half that half again —of names of persons coming within

their category, and whom they deem suited to the duties in question. If the hospital physician be excluded, and he who has become distinguished as a teacher of medical science, where, we should be glad to know, will a competent examiner be found? It will not, we presume, be said that the business of an examination is a mere farce: the day is gone by, in this country, when the mockery of a pretended ordeal would be tolerated; and with the efficiency of its examinations, we are persuaded, the new establishment will either stand or fall. Perhaps it is the object of the parties referred to, merely to pursue the ancient beaten track of testing candidates by the extent of their book knowledge, and to bestow honours on them in proportion to their degree of polish acquired by *grinding*. If so, let the pure and inexperienced examiners, recommended by the deputation, receive their appointments; but then let us hear no more of a University founded in the metropolis, and worthy of the present state of medical knowledge in Great Britain.

In sober sadness, it is a great misfortune to have an excellent project, like the present, marred by meddling fools or designing knaves; and never, we believe, was a grand undertaking more near being spoilt than is that of the Metropolitan University that is to be. Hospital physicians, and actual lecturers, — no matter how eminent their attainments and qualifications, — are objected to. May we, in that case, beg to be informed, how is an efficient examination to be given? By an efficient examination we mean one suitable to the present advanced state of medical science and practice: one that should be *practical* in the proper sense of the word, and not merely conducted by rote; one that should be held not only in the examination hall, but by the bed-side of the patient. Nor let it be said that this is innovation: call it by whatever name we may, the thing, however new here, is universally adopted in other countries, and most fitting to be introduced amongst us; it cannot be much longer excluded. Is it to be contemplated for a moment, that a new University, in the nineteenth century, and in the metropolis of England, is to be established, and that medical honours are to be distributed in it, without any system whereby proper discrimination may be observed? To pause for a reply were only contemptuous. The examination *must* be practical; and is it proper that, being so, it should be entrusted to other hands than the most competent?

Not only, as it appears to us, is there no alternative, but it is the most desirable proceeding, to select the medical examiners for the new institution from among the hospital physicians, and the most distinguished lecturers of the metropolis. Valid objection, we repeat, we can see none. That a man's own pupils may sometimes come before him, is a counterplea of but little force, — force, too, more apparent than real. How easily could it be so arranged that an examiner should not interfere, under such circumstances,—as has long been the custom in examining at the College of Surgeons;—and would not the very occasion call forth a feeling of impartiality, well adapted for the furtherance of justice?

So little, in short, can be urged against the propriety of having actual practitioners and eminent teachers to examine candidates, and so simple are the means of removing any possible objection, that we hesitate not strongly to recommend it as the wisest course which can be adopted.

The plan, on the other hand, of confiding so important a task to persons little conversant with practice, and wholly unconnected with the business

of teaching, is fraught with much absurdity and certain mischief. How, or where, we once more ask, can we find half a dozen men of this description fitted for the due discharge of the duty of examiners? The persons proposed, and we may say the persons talked of as likely to be appointed, can only be considered as mere amateurs in science — men deriving their professional information from books and the scanty resources of a limited private practice—men too, some of them, founding their claims to appointment, as we are given to understand, on still more questionable pretensions. With such nominations as these, should they unfortunately be made, it is utterly impossible that the professional public can be satisfied, or be otherwise than highly offended. For our own parts we would fain hope that the government will exercise a more sane discretion in the arrangements they intend to adopt. Should, however, our *fears* prove true, we can only enter our strong protest against the whole proceeding.

EFFECTS OF MATRIMONY ON LONGEVITY.

We beg to call the attention of our readers to the very interesting paper of Mr. Rickman on this subject, in our present number. The views of Dr. Casper, of Berlin, which, a short time since, made some impression upon us, and to which we gave some currency in this country by the circulation of our journal, are not Mr. Rickman's views. Our correspondent thoroughly exposes the insufficiency of the data on which the German statistician founds his inferences respecting the (supposed) longevity of married life; and matrimony is now proved to have no marked effect in prolonging the life of either man or woman. Mr. Rickman gives us a concluding hint, that *we* ought to have been more guarded in announcing the novel doctrines of Herr Casper, before we had satisfied ourselves of the validity of his facts and calculations. It will be recollected, however, that we gave them solely on the responsibility of their author: something, too, might be pleaded for us on the score of the research required for such investigations; but we can scarcely regret our having noticed the paradoxes of Dr. Casper, when, by so doing, we have elicited so able a refutation of them from the pen of Mr Rickman.

MR. TWEEDIE AND THE "FREE HOSPITAL."

In a subsequent page will be found the statement and appeal of Mr. Tweedie relative to the late proceedings in Greville-street. We must say that his case appears to us one of considerable hardship: he has been infamously treated by Franks—in which respect, however, he does not stand alone: other parties also seem to have poured out their little phials of petty malice upon him; but we doubt greatly whether quite too much is not made of the whole affair. After such testimony in his favour, and what we may call so complete an acquittal, surely Mr. Tweedie may very fairly shake the dust off his feet, and trouble himself no more about the business.

CLINICAL LECTURE

ON

CRUSHING THE STONE IN THE BLADDER,

Delivered at the Middlesex Hospital School, March 14, 1836,

By Sir Charles Bell.

I propose to-day giving you a clinical lecture on crushing the stone in the bladder. We are bound to address you on this subject by every motive that can actuate the humane mind. There is no torture which a man suffers greater than that from stone in the bladder; and there is no duty which you will have in after life to perform so oppressive, as that of the operation of lithotomy; for although in favourable circumstances it is safely done, yet, whilst any obscurity hangs over the condition of the patient, or his constitutional peculiarities, or as to the size of the stone, or the state of the bladder, it is not without danger. But independently of these reasons, I say we are bound to draw your attention especially to this subject, since the very house over our heads has been

built at the expense of those who have taken our promise to attend to the methods of removing the stone without cutting.

First, then, how stands the opinion regarding the operation of lithotomy. You may have heard patients declare that they would rather suffer the operation for the stone twice over, than bear the torture from its presence for one night. You may have heard them say that the operation of sounding for the stone is more painful than the operation of cutting.

The incisions for lithotomy, performed by a man properly educated as an anatomist and surgeon, are simply and quickly made; but in regard to the extraction of the stone from the bladder, it should be done very *very* slowly, and consequently the rapidity with which an operation is performed is not the mode of judging of the merits of the operator. There is not an authority in our profession who has not declared against judging of an operation by the time. The taking out of a stop-watch is an indication of improper education. In a late operation performed in our theatre by our assistant, I have understood that the watch was looked to. That indicates both bad teaching and bad example, and would almost incline one to believe, that these individuals had come to see the operation ill performed, instead of witnessing it carefully and well performed, in the mode they ought to imitate.

Still, gentlemen, these deep incisions, made on oneself, who can contemplate without shrinking? and therefore it is of incalculable benefit to have an operation in which these incisions are not necessary. The advantage is this, that when a man entertains a suspicion of stone in the bladder, he comes at once to his surgeon; whereas, heretofore, he would not allow himself to believe that he was so unfortunate. He lets time pass; he is unwilling even to be sounded, lest his worst suspicions should be confirmed: time passes, the stone gets to be of a large size, and then, indeed, there is danger from the operation of lithotomy. You have no notion how men shrink from the certainty that they have the stone, and linger on suffering from irritation until it is unbearable; and then, when the stone has acquired a great size, they are forced to submit, in unfavourable circumstances. Therefore I say it is of incalculable benefit to society, and to us especially, that there is an operation, simple and safe comparatively, which is offered to the contemplation of these sufferers, and which brings them earlier under cure. Let us, then, give our whole attention to this subject.

An unfortunate idea prevails, got up upon this occasion, I know not on what authority, that we have been all along under a misconception, and that the urinary bladder can bear a great deal more injury than we have imagined.

On this head I beg your particular attention. I have at various times pressed upon you the difference of sensibility in internal and external parts. I have shewn you that internal parts—the viscera—have their peculiar sensibility, and that it is totally different from that of the surfaces. But there is more than this: suppose that you are examining a patient with diseased liver, or under the suspicion that he has diseased liver. You lay him down, relax the abdomen, and press along the margins of the ribs, and feel the hardened edge of the liver. You ask him if he has pain on this pressure; he says "no." Or if, not feeling the liver, you press down the cartilages of the ribs to ascertain if there be morbid sensibility, indicative of inflammation, still he says that he suffers no pain. But by and by, when he sits down, and proceeds with the narrative of the disease, he becomes pale, speaks with difficulty, and tells you that he is now in great pain. There is a peculiarity in the sensibility of the liver different from that of the external parts; but it rises slowly after pressure. In the same way, to bring us nearer to the subject, if you are examining *per anum* the state of the prostate gland with the finger, and press all around to find if there be sensibility, or any mark of disease there, and you ask the patient—"have you pain here—have you pain there?" he says "no." But when you have withdrawn the finger, and after the examination has been finished some time, the patient begins to complain of the dull sensation which arises, and becomes at last very painful. So, again, with regard to the bladder, but more especially its neck, there is a certain pain, no doubt, felt by the patient during the introduction of instruments; but all the effect of the interference with the internal part is not shewn during your operation, but after it; so that if you are not careful, light of hand, and delicate with the patient, you are called back in the afternoon of the day, and there you find him in a paroxysm of suffering, cold and shivering, the bed shaking under him, and he is in a state most alarming to himself and his friends. Hours have passed, but the paroxysm is the indication of the injury you have in the morning committed upon the neck of the man's bladder. Do not, therefore, be deceived by this sort of new aphorism got up, that you may do a great deal more injury to the bladder without inconvenience,

than has been hitherto supposed; it is an entire mistake.

For the history of the operation of crushing the stone, you must go elsewhere. It is a long history, which I cannot undertake to follow up so as to appropriate the merit of the discovery to the right individuals. But when the operation was first performed in this country, they brought me an instrument similar to that which I now show you, but larger and stronger, and of which this might almost be said to be the model, for this is intended for a child. The instrument you perceive is straight; and here is another grand discovery, that you can pass a straight instrument into the urethra. This you certainly can do, but I fancy that, as anatomists, nobody will convince you but that there is a curve in the urethra, and although you can pass a straight instrument, you do certain violence to the curved urethra, more especially to the neck of the bladder. When I saw this instrument first, I said, "It appears to me a most dangerous instrument"; you see that it is a tube from which certain blades possessed of elasticity can be thrust out, and which, by their expansion, are prepared to seize the stone. I remarked, "suppose you get hold of the stone, and cannot break it, how can you withdraw the instrument?" The answer was very ingenious: "there is a wire to pass through this tube, which projects against the stone, and displaces it from the grasp of the forceps." That is good, it is ingenious; but suppose that we have got hold of the stone, and that by attempting to crush the stone, instead of effecting our object, the ends of the blades of the instrument bend, and are permanently expanded, what is then to be done? There was no answer to that question, except that it was not likely to happen. But it did happen:—it has happened not once, but several times. How often it has happened, and how often patients have died under this operation, and from what immediate causes, I am unable to state; and yet these misfortunes should be recorded. Several, I know, have died; but I shall speak of one case, of which I was a witness.

A much-respected gentleman had a stone in his bladder: he was unwilling, as most patients are, to suffer the operation of lithotomy, and called to his assistance the Parisian operator. He proceeded to his operation; he seized the stone, but in pressing down the instrument, the blades did not break off—that would have been of less consequence—but they became permanently expanded, and in this state the instrument was withdrawn through the prostate. (Think of the effects of withdrawing such an instrument through the prostate!) It was brought into the membranous part of the urethra, but farther it could not be withdrawn! What was to be done? There was a call for a pair of blacksmith's forceps—strong pincers; then the patient was placed as for lithotomy, the perineum was cut into, the bulb of the urethra opened, and the forceps applied to the blades to squeeze them together, in order that the instrument might be withdrawn along the urethra. Dr. Hume and Sir B. C. Brodie being in attendance upon the operation, said, "here is the incision as for lithotomy; why not proceed, and finish the operation?" They knew well, and you ought to know, and remember it, that an ineffectual operation for lithotomy, the stone remaining in the bladder, is generally fatal, because, in addition to the violence of the operation, there is permanent irritation from the presence of the stone. They determined that the stone should not remain in the patient's bladder; and so Sir B. C. Brodie, with characteristic decision and ability, immediately sent for his instruments, and performed the operation for lithotomy. It was after this period of the case that I was called in, and I saw that gentleman suffering gradual decay, in consequence of the severity of the operation—first, from the introduction of the instrument; secondly, from the operation of seizing, and the attempts to crush the stone; thirdly, from the violent withdrawal of the dilated instrument through the prostate; fourthly, from the incision into the bulb of the urethra and the formidable hæmorrhage; and fifthly, from the performance of the common operation of lithotomy. Can you wonder, then, that after lingering some weeks, the patient finally died?

So far, then, I maintain I was right in my conjecture regarding this instrument. It is a most villanous and dangerous instrument; and if you have been tempted to buy it, keep it till you grow rich, and give it to your butler to draw corks from a bottle.

With regard to the patient in the hospital, you see an old blind man suffering severely from the stone. On sounding the man, and dodging the instrument over the stone, I calculated that there was a stone about the size of a chesnut; and remarked that, if we are ever to perform this operation of bruising the stone, here is the instance; and I was prompted to think that I could do it (pardon me for saying so) with as light a hand, and with as much regard to the patient's feelings, as I had seen the operation performed. I performed the operation at three different times, and he is now discharged, well.

The operation is this:—In the first place the bladder must be injected, and for this reason, that the stone is apt to lurk

between the fleshy columns of the bladder. When the bladder is irritated by the presence of a calculus, fleshy columns arise, formed out of the fibres of the detrusor urinæ; by dilating the bladder you separate these, as it were, and force the stone out of the recesses between the columns; and then again, in catching the stone, you are in no danger of including the folds of the bladder when it is distended. That is the reason of filling the bladder with tepid water. In the next place, you lay the patient so that the stone falls a little to one side.

I have said, in speaking of lithotomy, that the surgeon who sounds dexterously will perform the operation well, because, by sounding well, he calculates the depth of the bladder, and the actual position of the stone, and he can get the stone to that recess where he is sure to strike it. If he acquire a proper notion of the position and size of the stone, the operation of lithotomy is comparatively simple. So also he that can discover the stone with little pain to the patient, is likely to succeed in this operation (not forcing in the instrument, and striking with violence against the stone, but rather, by turning the patient, bringing the stone by gravitation into contact with the instrument). I say that the surgeon ascertaining thus the actual position of the stone, will perform the operation of catching it and crushing it easily.

As to the instrument which you are to introduce to crush the stone, this which I now present to you is it. You see at once that it is a totally different instrument from that which I before showed you. There is an advantage in the curved form; it may be very easily introduced into the neck of the bladder without inflicting pain. But the greatest advantage of this instrument is its strength. This instrument is the invention or the improvement of a person who certainly will not hide his candle under a bushel; and he is quite prepared to stand his ground with any inventor in Paris or elsewhere. Notwithstanding there is a sort of conceit about him, yet I value the instrument on account of its form and strength; for I repeat, I care not so much about breaking the instrument, as the fragment can be withdrawn with the stone by lithotomy; but bending the instrument is the most formidable thing, inasmuch as we can neither let it remain nor withdraw it without a rude and painful operation. Indeed, all these instruments should be proved like a piece of ordnance before they are used. Now, observe how it is to be used. If, for example, the stone be of the size of a walnut, we must then prepare that the blades shall separate to that extent. Having introduced the instrument into the bladder, and turned it to the side on which the patient lies, and felt the stone, you slowly open the blades by withdrawing the upper one thus; and perhaps you feel the patient flinch a little. You saw that as soon as I had chucked upon the stone, it was immediately seized. There is not the slightest difficulty in this part of the operation, neither is there pain if you do not open the instrument suddenly, and to a great extent. Take time, do it delicately and nicely, and there is neither difficulty to you nor pain to your patient. During the operation, I was desirous to know what pain was inflicted by the operation. I requested the patient to tell me whether he was suffering pain. "Oh," said he, "I cannot expect to get rid of a stone in the bladder without pain." "Nay; but tell me," I replied, "how do you feel—are you suffering much pain?" "Oh, you know there must be pain." But he never winced,—never moved a muscle, never interrupted his chat,—and therefore I must presume that the man was not suffering; for if he endured pain, he must have had extraordinary fortitude neither to wince, nor cry, nor even to change his voice, but readily to converse with me during the operation.

When the stone is seized, you can move the instrument to any part of the bladder you choose. You cannot, by pushing down the button attached to the sliding blade with your finger, crush the stone; but there is a screw, having great mechanical power, and you must use it, not by turning it uniformly, but by bringing it back again, and so working it as to grind the stone gradually, and by distinct blows. By this means you break the stone down as if it were bruised with a hammer; and it is not so apt to break and fly by each successive impulse as by screwing down the sliding blade at once by the mechanical power of the screw. The stone being thus crushed, and a great portion of the fragments being brought out in the grasp of the instrument, it is so far satisfactory. It will sometimes happen that the stone will remain, choaking up the instrument, and you can with difficulty get the blades together. The meaning of this slit, which is otherwise to be regretted, as weakening the instrument, is to let the *debris* be forced through. You calculate, from the position of the sliding ring along this scale, how far the blades remain apart; and they must be brought nearer, almost together, before you attempt to withdraw the instrument. There is a part of the operation here which I like, as being ingenious; a vice having attached to it a heavy mass of metal, is screwed upon the shaft, which belongs to the further and fixed blade, and then the other shaft is struck down with smart blows of the steel hammer,

until the upper blade is so far pressed upon the lower, that the instrument can be withdrawn. What is the meaning of this appended mass of metal? There is a *vis inertiæ* in it; and accordingly, in striking the instrument, instead of endangering the bladder, the impulse is resisted by the appended mass, and you can therefore give a smart blow without any shock.

Is it not an admirable thing to bruise a stone into these fragments [handing round a bottle containing them]?—and does it not appear to you a very simple thing?

But you have not yet considered the source of pain and danger. The operation, I say, is not a painful one, but the consequences are sometimes very formidable. In the first place, there is a great uncertainty of getting the stone altogether away; there is a possibility of some fragment remaining, and if it should, there is great pain, and another stone will form upon it as a nucleus. I was consulted by a gentleman not far removed from our hospital, on whom this operation was performed. He seemed in just such a condition as the patient whom you have seen, and the operation was perhaps as easily done. There had been two or three successive operations; and the patient said, "I think I will do handsomely—I will give the operator 100 guineas." "No," said the operator; "my fee is 400 guineas!" He gave his 400 guineas; and when I sounded him some considerable time afterwards, I found there was still a stone in the bladder, and that the pain had returned, and the glairy deposit in the urine. I was quite satisfied with my one-pound-one; but still I could not help drawing a little contrast between my honorarium and that thrown into the "egregious maw" of this cormorant. I felt that it would then have been easy to crush the stone at a common visit. It is possible that in this instance a new stone had descended from the kidneys. But nevertheless, it is a fact, that with the most experienced performers a portion of the stone, like a shell, is apt to remain, and to form the nucleus of another stone. I do not consider this as a great objection to the operation, but it points out to you the necessity of not being too sanguine that you have removed every part; and it shows the necessity of again and again examining the bladder, and washing it out carefully.

There is not merely danger of a portion remaining in the bladder, but worse than this—a fragment, such as you have in that bottle, may stick in the orifice of the bladder, or in the lacunæ of the prostate, and then the suffering of the patient is beyond expression. The contraction of the neck of the bladder upon the sharp stone, the inability to discharge the urine, the spasm that takes place in the bladder, and the inflammatory condition of the prostate, are all very serious consequences, and attended with great suffering.

You can the better comprehend all this because you have seen it in my patient. You saw that after the second operation he suffered excessively, from a sort of paroxysm, which implied no more than might have taken place if a very rude hand had forced a large bougie through the prostate. But afterwards he suffered in a different way—viz. from a portion of the stone lodging in the neck of the bladder, so that he had frequent calls to make urine, and purulent and mucous discharge from the neck of the bladder.

In a private patient, whom I attended during the progress of the operation, it was necessary to introduce the catheter and inject tepid water, so as to push and wash back the fragment into the bladder, to give temporary relief.

It was on account of this patient's suffering that I got an instrument made for injecting the bladder. I did not know that this very excellent instrument [presenting it] had been provided and was in the case. I commend this to you for your adoption: it combines the means of holding a portion of the stone, with the uses of a catheter. You can introduce this and inject the bladder, and then allow the bladder to empty itself through this tube; trusting, that if there be a portion of stone remaining, it will come, by the force of the stream, into the groove, and then you can take hold of it and withdraw it. It is a most ingenious and excellent addition to the other instruments.

At one time our patient had frequent calls to make water, and discharged great quantities of glairy mucus. Those were the symptoms of the portions sticking near the orifice of the bladder. This mucus you saw tough, hanging from the pot; and in some cases it is discharged bolt out in a mass, so as to give the patient the sensation of a large body being discharged.

Such is the result of a broken portion of the stone (which is often like the broken shell of an almond), sticking and clinging to the prostate, or entering into the dilated part of the urethra which is within the prostate, obstructing the urine mechanically, and at the same time causing painful spasm.

One operation of crushing will not be sufficient; nor two, nor three; it must be repeated again and again, and it is only a small stone which you ought to attempt to crush: you will be baffled by a large stone, and you must acknowledge that when there is a large one it is a case in which it will be necessary to perform lithotomy. When there is a small stone, this operation

is safely performed, and with the best success; but, as I said, not by one operation, but by several. The suffering, I repeat, is not during the operation, but afterwards; nor must it be concealed that many have died in consequence of this operation. If I have a feeling against the operators, it is from finding there have been deaths undivulged, and not fairly put in balance when the operation has been contrasted with lithotomy.

I believe I have fairly stated to you all that has come to my knowledge—that which I have seen with my eyes and felt with my hands; keeping out of sight all that has been said in controversy: in fact, I know very little about the controversies which have been entertained on this subject.

In conclusion, then, consider the operation as belonging to your profession, and as a thing you can do with propriety and efficiency, if you know the form and position of the bladder—if you calculate the gravitation and lodgment of the stone, and if you can sound well and safely. All that I have to recommend to you is, that, having crushed the stone, you should see that the fragments are removed, and take care to wash the neck of the bladder during the paroxysm. I believe there is an instrument to slit and open the passage, and allow the stone to escape: it is highly improper to use such an instrument, and the invention of it is only declaring demonstratively the severity of the suffering from the sticking of the fragments in the passage. On the whole, this is a very important operation—a real accession to our means of giving relief: it brings patients to your hands, when you can do them essential service; it prevents them lingering and hanging off till the stone is too large for the operation of crushing, or even of lithotomy.

I look upon the ingenious inventions exhibited in these instruments [there were many on the table], as promising us means of breaking the stone in the operation of lithotomy. If the operation of lithotomy is to be limited to the cases where the stone is large, then will the character of the operation quickly decline: for there is no accident in lithotomy which, by care and dexterity, may not be obviated, but those which attend the extraction of a large stone, and hardly any contrivance or exercise of ingenuity will mitigate the evil. To do the operation without violence or tearing, is to make it certainly successful; and for this purpose the stone, if large, must be divided, not brought through entire. It is not an operation for display, but to ensure you a better reward than the approbation of a whole theatre of gentlemen, with watches in their hands.

SCHOOL OF PHYSIC IN IRELAND.

DR. MACARTNEY AND DR. LENDRICK—CORRESPONDENCE, &c.

To the Editor of the Medical Gazette.

SIR,

IN a letter addressed to you by Dr. Lendrick, he complains that the communications between the Board of Trinity College and me, during the years 1833 and 1834, have not been published. I did not think it necessary to print more of the correspondence than was sufficient to explain the facts, and account for my conduct, not calculating that any person acquainted with the history of medical education, would, in the present day, become the champion of imperfect instruction. I now send you the intermediate correspondence,—which Dr. Lendrick will find does not strengthen his case, but, on the contrary, contains answers to almost all the arguments employed in his letter.

In addition, I wish to state the grounds on which any of the hours he mentions would be unfit for my lectures on surgery. 1st. The morning hours are given up to the practice of the hospitals, which most of the pupils attend. 2d. The hour of twelve would be impracticable to the same person teaching anatomy at one. 3d. Evening lectures have been tried in Dublin by others, and myself, and relinquished on account of the irregular conduct of the pupils; and under the circumstances in which I am placed, they would be peculiarly objectionable, as the entrance to the anatomy house is through a lane, where there is a low tavern, in which several of the students have been led into scandalous excesses even during the day; and further, a night hour is unsuitable for a course of surgery, in which operations are shewn. In London the operations were performed in the anatomical course, which would be inconsistent with the Edinburgh regulations. At all events, it must be manifest that I would not have returned money, and surrendered my class into the hands of other teachers, if I could have with propriety employed any of the hours which Dr. Lendrick recommends.

If the order of the Board, of 31st October, 1834, communicated to Dr. Barker by the Provost, be enforced, the instruction on both anatomy and surgery will be perfectly useless, and will be sought for in other places than the School of Physic in Ireland. I do not impute to Dr. Lendrick any wish to injure the school with which he is connected, but I attribute to him, as

well as others concerned in this transaction, very short-sighted views of their own interest.—I am, sir,

Your very obedient servant,
JAMES MACARTNEY.

Dublin, March 12, 1836.

From Dr. Wray to Dr. Lendrick.

Dear Lendrick,—I am directed by the Board, as Registrar, to say that the only lecture given from three to four o'clock, which will be required by the Board as a qualification for a *liciat ad examinandum*, is that given by the Professor of the Practice of Medicine.

Believe me, yours truly,
HEN. WRAY.

Board Room,
November 9, 1823.

From Dr. Macartney to Dr. Barker.

Dear Dr.,—As it is probable I shall not be able to attend the meeting of the professors, for the purpose of framing the advertisement of the lectures, I have to request that arrangements may be made for allowing me the necessary number of day hours for the two courses of anatomy and surgery. If I were to abbreviate both those courses, so as to give them at *one* hour, certificates of *neither* would be received in Edinburgh; the effect of which would be not merely to injure, but destroy the school. The character of the Dublin school at present is lowered by having the course of surgery discredited on account of its brevity.

It has been hitherto thought desirable to provide as much as possible the opportunities of giving at home the education required for the medical degree. This was the very ground on which Dr. Montgomery urged his claims for having his lectures recognized. At present pupils are compelled to take in Edinburgh a course of surgery of sufficient length, because I have not been allowed an hour for the purpose here, although it is as much my duty, according to the constitution of the School of Physic in Ireland, to teach surgery in a competent manner as anatomy. I have, however, now resolved to give the courses on the two subjects of which I am the Professor, of a length consistent with the advanced state of our knowledge on both subjects; and if distinct hours be not allotted for this purpose, I must only take those which will be most convenient to the class. I send you my printed advertisement.

Yours truly,
JAMES MACARTNEY.

Lucan, Aug. 25, 1834.

From the Provost to Dr. Barker.

(Communicated to Dr. Lendrick, Nov. 25, 1834.)

My dear Dr.,—I have laid before the Board this day the *representation* of the Professors of the School of Physic, and the Board have accordingly directed the Registrar to inform the Professor of Anatomy and Surgery, that they will consider the lectures on these subjects as constituting but one course, for attendance on which the students will be entitled to receive but one certificate from the *Registrar*: also, that they will not recognize any medical lectures delivered at three o'clock, but those on the practice of medicine.

I remain, sir, &c.
B. LLOYD.

October 31, 1834.

From Dr. Phipps to Dr. Macartney.

Sir,—I am directed by the Provost and Senior Fellows to direct you to refrain from lecturing at one of those hours which have been already appropriated to the lectures of another Professor of the School of Physic.

By order of the Board,
ROBT. PHIPPS,
Registrar.

Trinity College,
Dec. 13, 1834.

From Dr. Macartney to Dr. Phipps.

Sir,—I have to acknowledge the receipt of your letter, conveying to me the direction of the Provost and Senior Fellows, that I should refrain from lecturing at three o'clock.

I am sorry it was thought necessary to take this step from information derived from *ex parte* statements; and I am convinced the Board have issued this order without knowing what consequences would result from a compliance with it. I cannot suppose that it is desired to render the certificates of the Professor of Anatomy and Surgery useless to students, by making his courses so imperfect, that they would be deservedly discredited in every institution in this country. Would it tend to the reputation or the interest of Trinity College, or of that which in the act of Parliament is named the "*Complete School of Physic*," to abolish or restrict any part of the course of medical study, at a time when in all other Universities, including Oxford and Cambridge, it is greatly improved? Would it not have the appearance of partiality (for favouritism I am bound to presume does not exist), to compel students to seek a full course on surgery in Edinburgh, when it can be had at home; while at the same time it is made imperative to attend midwifery *here*, although not given by a legally constituted Professor in the School of Physic?

Although the Provost and Fellows may

hold the anatomical and surgical courses to be so much inferior to that on the practice of physic, that they think the former should give place to the latter, or rather to the fancied interests of the Professor of Physic, yet I cannot believe that it is intended to forbid students who have no wish or intention to attend Dr. Lendrick, occupying themselves with another subject at three o'clock.

As the Board seem to be quite unacquainted with the bearings of the case, I shall state some facts for their information.

For many years I have not been able to give two courses at *one* hour each day in the week, nor can it be done without mutilating one or both subjects.

I have been in the habit of lecturing two, three, or sometimes four times in the week, at three o'clock, on surgery,—of giving no holidays at Christmas,—of prolonging the lectures sometimes into the middle of May,—and towards the end of the course lecturing three times a-day, thereby producing very great (and what perhaps might be deemed unjustifiable) inconvenience to the pupils; notwithstanding, I have been obliged to condense and abridge much of the surgical course,—as the lectures on fractures, luxations, hernia, the venereal disease; and omit altogether two very important branches—the diseases of the skin and eye—subjects which have been so much extended by modern improvements.

I lectured at three o'clock before Dr. Lendrick was elected, and was complained of by the College of Physicians, at the instance of Dr. Osborne, who was acting as *locum tenens*. When the subject was discussed at that time, the Provost advised me to persevere with my lectures, and disregard complaints from *all* quarters; and this advice I followed, so that Dr. Lendrick found me using three o'clock when he was elected. I now appeal from the Provost of 1831 to the Provost of 1832, being satisfied that I have not deserved any unfavourable change in his sentiments.

Since that period the Board have made regulations forbidding the attendance on more than *three* Professors in the same year, which gives so much latitude, that two Professors lecturing at the same hour can produce no inconvenience, except from the merest accident, which would not occur again. A student *might* attend the practice of physic during *three* seasons, but I never heard of any attending more than once.

When there is a full course of medical education, interference of hours is unavoidable; several of the courses interfere in Edinburgh and on the continent. It is not desirable that the subjects I teach should be studied the same year with the practice of physic. Anatomy and surgery ought to precede; and wherever there is a rule for education, they do precede, the practice of physic.

It is quite manifest that I gain no advantage from lecturing at three o'clock on surgery, if another hour were at all convenient to the pupils, or practicable with respect to the subject,—and it so happens that the hour of twelve, offered to me by the other Professors (apparently because it would not suit me), would answer extremely well for Dr. Lendrick, as all the lectures at Sir Patrick Dun's (except Dr. Graves') would then be consecutive, which would save to the pupils that time at lecture they now spend passing backwards and forwards.

In the Edinburgh University and the College of Surgeons, five lectures in the week are required for anatomy, and as many on surgery. The College of Surgeons of London demand as many for anatomy, and *at least* three in the week on surgery. The Apothecaries' Company require the same number for anatomy. The College of Physicians in Ireland, even from *graduates* of the University, insist upon a distinct course of surgery, such as I could not give, using only one hour in the day. The consequence of depriving me of a *second* hour, would evidently be that my certificates would cease to be qualifications; and once destroy the anatomical and surgical courses of instruction, the school would speedily fall back to the state I formerly knew it, *i. e.* empty benches in place of pupils, and three, four, or five graduations in medicine in the year.

In your letter you say that the hour of 3 was previously appropriated to another Professor. I beg to observe that the law gives no authority to appropriate or determine what hour a Professor is to use. This matter has always been left to private arrangement, it not being supposed possible that it would require the interference of higher powers, nor could there have been any difficulty in the present case, if the other Professors had been as much disposed to accommodate me as their own interests would dictate, if they could perceive them.

The observations I have made apply to the past and future seasons, but with regard to this year, no change can now be made which could benefit any party concerned. The period is gone by in which pupils can with propriety be received by *any* Professor, with the intention of inserting their names in his return to the senior lecturer, or of granting them certificates.

Yours very truly,

James Macartney.

Dec. 16th, 1831.

From Dr. Phipps to Dr. Macartney.

SIR,

I have read your letter to the Board, and am directed to inform you, that they will not require you to refrain from lecturing at the hour of three o'clock, for the remainder of the present session; but that they will not extend this indulgence beyond that period.—I am,

Your very obedient servant,
ROBERT PHIPPS, Registrar.

Trinity College, Dec. 26, 1834.

From Dr. Macartney to Dr. Phipps.

SIR,

I am sorry to find by your letter of the 26th instant, that the Board have not bestowed sufficient consideration on the subject of my surgical lectures, to enable them to arrive at the real state of the case.

The question is not whether I shall lecture at three o'clock, but whether the course on surgery is to be given at a practicable hour, so as to make it of any value to the pupils, or to be abolished, as a part of the education in the University. The language used in your letter proves that the Board have mistaken my objects altogether. You say that the *indulgence* will not be extended to me after this season, that is, the indulgence of giving *two* full courses for the price of *one*, in order to discharge the duties of a double Professorship, maintain my own reputation, and the character of the school. I asked no favour nor indulgence, and it is well I had no occasion, as it seems I would have been refused: I merely claim the right of being unmolested in the conscientious performance of my duty. It is, perhaps, looking too far forward to pronounce what is to take place next year, or how medical education may be regulated.

The Board have already come to *four* different decisions on this subject, and until the matter shall be more closely investigated than it has been yet, I do not consider it as finally settled.—I am, sir,

Your obedient servant,
JAMES MACARTNEY.

Dec. 27, 1834.

DISMISSAL OF MEDICAL OFFICERS, FOR ALLEGED QUACKERY.

MR. A. TWEEDIE'S APPEAL.

To the Members of the Medical Profession.

GENTLEMEN,

You will have observed by the newspapers, that the Governors of a public institution, entitled the "Free Hospital," Greville Street, have removed their resident apothecary, Mr. Hentsch, and one of their unpaid surgeons, Mr. Tweedie (myself), from their respective offices, on the alleged charge of having administered and recommended a nostrum called "Franks' Specific Solution."

Such a proceeding is without precedent in the medical history of this country; and I deem it not only respectful to you, but due to my own reputation, to lay before you a brief statement of the facts relating to it.

About the beginning of February, 1835, Mr. Hentsch, the resident apothecary of the "Free Hospital," mentioned to me that Mr. Franks had succeeded, by distillation and otherwise, in freeing the "balsam of copaiba" from much of its impurity and irritating properties, whereby a quantity of greenish-olive ropy sediment was removed; and the remedy so purified had been found by him to be more grateful to the stomach, and more efficacious as a medicine, than was the balsam itself before it had been so prepared. He requested me to give it a trial.

Now Mr. Franks was not at that time advertising like a quack; he was a regular medical practitioner, residing officially at the South London Dispensary, and also a Governor of this "Free Hospital;" and observing, besides, that Mr. Green and Mr. South, at St. Thomas's Hospital; Mr. Bransby Cooper, at Guy's; Sir Astley Cooper, Sir Benjamin Brodie, and other eminent surgeons, were making trial of the preparation, I had no hesitation in prescribing it publicly to my patients at the "Free Hospital."

The result justified me in speaking favourably of it; so that when, two months after this, Mr. Franks called and asked me for my written opinion, I had no suspicion of the use that would be made of it; and in imitation of the example of Mr. Green, Mr. B. Cooper, and others, I wrote and gave him, without inquiry, a professional statement of the result of my experience of his "preparation of *copaiba*."

Since these things, Mr. Franks, judging, no doubt, that more emolument would result to himself from selling what *he* chose to make a quack medicine, than from the orthodox pursuit of his profession, has taken out a patent for his "solution of *copaiba*," and has published our letters, mutilated and garbled to suit his purpose, in hand-bills and advertisements, as though we sanctioned a secret remedy, which he now designated "Franks' Specific Solution," leaving out all mention of "*copaiba*."

The extreme indecency of such a proceeding struck me so forcibly, that within two hours after one of these hand-bills had been pointed out to me, I had written Mr.

Franks a note, expressive of my disapprobation, and requested, as a personal favour, that he would withdraw my letter altogether from his future publications.

To this note I have never been favoured with a reply.

Shortly after this, learning that Mr. Green was about to apply to the Court of Chancery for an injunction to restrain Mr. Franks from the misuse of his testimonial, I obtained, through Mr. B. Cooper's kindness, an interview with Mr. Green, who very liberally permitted me to add my affidavit of facts to those of himself and the several other aggrieved parties.

The Vice-Chancellor's answer to this was, that as no stipulation had been made at the time of writing the letters, he had not the power of preventing Mr. Franks from publishing them, his authority only empowering him to order, that to whatever purpose they might be applied, they should not be garbled or altered in any way from the original.

Such, gentlemen, is the entire story of my connexion with this nostrum,—this the extent of my offending. Without note or comment, I leave it to you to determine, after the perusal of the following documents, whether you will agree with the Council of the College of Surgeons in acquitting me, or with the newly-made governors of the "Free Hospital" in pronouncing my condemnation.

I subjoin the reply of the Council of the College of Surgeons to my statement, and also the resolution of the governors of the "Free Hospital," begging of you to contrast the one with the other, and to compare the facts of the case with the allegations of the resolution itself.

The Answer of the Council of the College of Surgeons.

"Royal College of Surgeons, in London, Jan. 27, 1836.

"Sir,—Having laid before the Council "of this College your letter of the 25th "instant, and its accompanying statement, "I am directed to acquaint you that the "Council are precluded from giving an "official or collective opinion on the sub-"ject; but they cannot believe that the "governors of any public institution will "be inclined to remove a surgeon from "their establishment, merely for trying a "new mode of administering an old and "well-known medicine."—"I am, sir,

"Your most obedient servant,

(Signed) "Edw. Belfour, *Secretary.*

"*To Alex. Tweedie, Esq. &c. &c.*"

The Resolution of the Governors of the "Free Hospital," on the 1st of March.

"That it appears to this meeting, that "Mr. Alexander Tweedie, one of the sur-"geons of this hospital, has, without con-"sulting with his medical brethren, ad-"ministered to the patients under his "care, a nostrum called 'Franks' Specific "Solution,' the properties of which could "not be known to him; and has, in direct "violation of the principle upon which "this hospital was founded, given a writ-"ten testimonial, recommending such "nostrum, which recommendation being "most extensively advertised, and appear-"ing on the face of it to emanate from a "surgeon of this establishment, cannot "fail to injure the charity most seriously "in the estimation of the public, whereby "its utility will be lessened, its prosperity "retarded, and the reputation of the other "medical officers materially affected.

"Under these considerations, it becomes "the painful duty of the meeting to re-"solve, that Mr. Alexander Tweedie be no "longer a surgeon of this hospital."

Having thus detailed the abstract facts of the case, permit me briefly to call your attention to the method and means by which our removal has been brought about.

About six months before the date of our removal, a motion of censure for this very business had been proposed against us by my then colleague, Mr. William Marsden, at a quarterly general meeting of the governors: the subject received ample discussion, and the explanation I gave was so satisfactory, that, by a large majority, the subscribers referred the matter to the officers of the establishment, and negatived the vote of censure. The gentlemen accordingly met together, and came unanimously to a resolution that was calculated to set the matter finally at rest. This resolution was received and confirmed without comment at a subsequent meeting of the committee of management.

It was with no small surprise, therefore, that myself in particular, and many old governors in general, received the announcement of a new attempt being made to re-open a question that had been, to all appearance, finally settled six months ago.

I believe, firmly, that the majority of the old and legitimate governors of the charity were, in truth, no parties to the scene that has recently been enacted.

Prior to the meeting at which our removal was effected, reports had been insidiously circulated, calculated to prejudice the minds of the subscribers, by reason of their partial and one-sided character. It was rumoured that I was connected, and on friendly terms, with Mr. Franks—which is not the fact:—it was insinuated that I had *been paid* for my letter—which is on the face of it a falsehood:—and it was studiously NOT stated, that I had made use of every endeavour in my power to put a stop to the nuisance. In short, it was given

out that I was physicking the poor with quack medicine, and that I was nothing but a quack myself.

But the gravest act of misrepresentation of which I have to complain, is one that emanated from my late colleague, Mr. Marsden. Whether done in ignorance of the fact or not, makes little difference; for Mr. W. M., unmindful of the delicacy due to a colleague in my situation, thought proper to issue a circular to the Governors, *on the eve of their meeting*, identifying himself with the business, gravely charging us with having recommended the "indiscriminate use" of a nostrum, and with having been guilty of "a direct breach of professional etiquette;" alleging, moreover, that this was "a circumstance (identified as I am with the hospital) which is seriously injuring both my reputation and practice."

In each of Mr. William Marsden's circulars came enclosed a caricature hand-bill, purporting to be "Copy from bills issued by Mr. Franks." From this caricature it was made to appear that I had given a "First testimonial," and a "Second testimonial;" whereas, in truth, I had never writen but one letter—that headed, "First testimonial from Alexander Tweedie, Esq." &c., being, in fact, the mutilated and garbled one published by Mr. Franks, before the Vice Chancellor's decision; and that headed "Second testimonial from Alexander Tweedie, Esq." &c. being the real letter that he has published since that decision.

I am willing to believe that such things might possibly have been circulated in ignorance of the truth; but the effect certainly was to mislead Governors, and to make them imagine that I had verily written *two testimonials.*

But the 23d February last, the evening of meeting, arrived, and disclosed a scene that had, perhaps, not been anticipated by the very leaders in the transaction. Nearly 400 persons (many of whom have been recognized not to be subscribers at all, and who had no right to be present) occupied the great room of the Gray's-inn Coffee-house; absolutely a larger number than appears in the printed list of Governors, including ladies, peers, corporation, parishes, and all.

In this assembly it was impracticable for any gentleman favourable to Mr. Hentsch or myself to obtain a hearing; clamour supplied the place of reason; they came to vote, not to inquire; and they had determined to have it all their own way. The following will serve to illustrate the spirit of the thing. A gentleman rose to address the meeting, "as a professional man." At these words, the uproar and confusion that resulted was beyond description; but the speaker was an adroit tactician, for he lifted up his voice, exclaiming, "I am going to speak in favour of Mr. Marsden's motion." Immediately the meeting became tranquil, and he was allowed to proceed.

After Mr. Hentsch was removed, there were those present who wanted me to resign; but I think you will agree with me, that such an act, with the fear of expulsion before my eyes, would have been suicidal of my reputation, and not worthy of that noble profession of which, I trust, I still continue a respectable and not dishonoured member.

Accordingly, when my turn for expulsion arrived, I first protested against the illegality of being tried by a meeting constituted as that meeting was, and then having made my statement for the satisfaction of the respectable governors, and having heard from my colleagues, Dr. Uwins, Dr. Ryan, and Mr. Lucas, that so far from considering their "reputations likely to be materially affected" by my conduct, "they were prepared to resign with me if the meeting persisted in so gross an act of injustice as to remove me;" and from another colleague, Mr. Jones, that although he would not resign, he did not consider his reputation to be of so sensitive a nature as to sustain any injury from such a cause: having done these things, and the meeting becoming so uproarious that it was evident to the real governors of the institution that justice would not be done, I, in company with a large number of respectable friends, retired, and left the meeting to sustain the whole responsibility of carrying, in our absence, "by a majority of five to one," the resolution, of which a copy has been given.

It was not my original intention to have intruded my grievance thus before the professional public, but circumstances and the advice of friends have induced me to alter that determination. Allow me, gentlemen, to indulge the hope, that in your estimation I shall be exonerated from blame, as I have been in the declaration of the Council of the College of Surgeons.

I have nothing further to say—than to acknowledge with pride and gratitude, thus publicly, the assistance and unsolicited support afforded to me on the occasion, not only by many of the eldest and most respectable lay-subscribers of the charity, but also by a number of medical friends, amongst whom Mr. Bransby Cooper was the foremost, who, of their own accord, kindly came forward to bear testimony in my favour.—I am, gentlemen,

Yours faithfully,

ALEXANDER TWEEDIE, M.R.C.S.

On Warming and Ventilating Houses.

It was announced that Dr. Arnott was to give some new views on this subject this evening, and the theatre was filled to hear him. But we regret that not happening to procure a seat on any of the benches near the lecturer, we were not within ear-shot of a tenth part of what he said. Dr. Arnott ought to contrive some ingenious method of diffusing his *voice* through a large apartment, as he does heat and air: and if we might suggest a simple plan to him for the purpose, it would be to *speak up*, and fancy himself talking to somebody at a distance. What we did hear, principally related to the importance of warming houses economically, and the propriety of adopting Dr. Arnott's new invention of a sheet-iron box, for generating hot air, and radiating heat from its surface. Dr. A. described the various methods which he previously tried—such as setting up in his library a box full of hot water kept at a given temperature, by being in connexion with a boiler on the kitchen fire, then boiling the water within the box, and ultimately putting into the iron inclosure a small stove with lighted fuel, admitting cold air below, causing it to circulate within, and regulating all by a throttle valve, and compound metal bar. His plans of ventilation were wholly unintelligible, as he referred perpetually to drawings in faint outline, and placed at such a distance as to defy the most piercing sight: they were, as he himself facetiously observed, "drawings on the imagination:" but we thought it rather *too much* for the Dr. to tax the imagination, in addition to the senses of sight and hearing.

NOTICES.

We treated Dr. Kerrison uncourteously last week, by abridging him of his legitimate title. His paper on Tic Douloureux was announced on the wrapper as by R. M. Kerrison, *Esq.*: this was mere accident, which we hope Dr. K. will overlook.

It would be desirable to have the remainder of the MS. on the "Animal Fluids," ere we put the first part in the printer's hands. We should be glad to commence the series in the first number of our new volume.

Errata.—In Mr Brett's paper on Urinary Deposits, p. 799, 2d col. line 38 from the top, *for* "in this colouring matter," *read* "in this form of deposit." Page 849, 2d col. line 8 from the top, *for* "It is, however, maintained," *read* "It is *not*, however, maintained." Page 897, 1st col. line 11 from the bottom, instead of placing the period after the word "colour," place it after the word "*urine*;" and instead of reading, "from any of the urinary salts which may become precipitated," &c. *read* "For any of the urinary salts," &c.; and instead of "olizarine," read "alizarine." Page 924, 2d col. line 28 from top, *for* "three reagents," *read* "those reagents."

Mr. Belinaye requests us to supply an omitted phrase in his paper of last week. At p. 946, 2d col. line 48, after "83 in 100 died in the hospital," *read* "or in private dwellings."

LECTURES

ON

MATERIA MEDICA, OR PHARMACOLOGY, AND GENERAL THERAPEUTICS,

Delivered at the Aldersgate School of Medicine,

BY JON. PEREIRA, ESQ., F.L.S.

LECTURE XXVI.

CARBONIC ACID.

THE last of the mineral acids which I shall notice is the carbonic.

History and synonymes.—Although the ancients were acquainted with its poisonous properties, the nature of carbonic acid gas was first explained by Dr. Black, in 1757. The *spiritus lethalis* of the ancients is evidently this acid, as is also the *spiritus sylvestris*, or *gas*, of Paracelsus and Van Helmont. *Fixed air*, *acid vapour*, and *aërial acid*, are other names by which it has been known.

Native state.—You are aware it is a constituent of the atmosphere. In some parts of the world it is evolved from the earth in large quantities, particularly in old volcanic countries. Thus in the vicinity of the Lake of Laach, Bischof estimates the exhalation as equal to 600,000 lbs. daily, or 219,000,000 lbs. annually! Some of the acid evolved in the Brohlthal, on the Rhine, he employs in the manufacture of chemical preparations on the large scale. You are, I presume, familiar, by report, with the *Grotto del Cane*. It is a cavity in a rock, through the fissures of which carbonic acid is evolved. It has received its name from the practice of putting dogs into it, who fall down suffocated. I cannot resist alluding to the *Valley of Poison*, in Java, which has been described by Mr. Loudon. From this gentleman's statement, it appears to be a cavity of an oval form, about three-quarters of a mile in circumference, and from thirty to thirty-five feet deep; filled to the height of about eighteen feet with carbonic acid gas. The bottom of it is covered with the skeletons of men and various other animals, who have fallen victims to its destructive operation. If a traveller should be so unfortunate as to enter it, he cannot be sensible of his danger until too late to return. Mr. Loudon thrust a dog in; he fell in fourteen seconds. A fowl thrown in appeared to be dead before it reached the ground!! In mines and wells we sometimes meet with this gas, and in these situations it is usually termed *choke damp*, the word damp being evidently derived from the German *dampf*, vapour. Few mineral waters are without this acid, and in some it exists in such large quantities as to render them sparkling and effervescing. In combination with lime, it is one of the most common constituents of the crust of our globe. Lastly, it is evolved both by vegetables and animals.

Preparation.— Pour hydrochloric acid, diluted with four or five times its volume of water, on some pieces of marble contained in a glass retort. Carbonic acid gas is copiously evolved, and may be collected over water. By the mutual reaction of the hydrochloric acid and carbonate of lime (marble), water, chloride of calcium, and carbonic acid, result.

Re-agents.	Results.
$\dot{\mathrm{Ca}}\,\ddot{\mathrm{C}}$	$\ddot{\mathrm{C}}$
$\mathrm{H\,Chl}$	$\dot{\mathrm{H}}$
	$\mathrm{Ca\,Chl}$

Properties. — At common temperatures and pressures it is gaseous, invisible, and odourless, (or nearly so). Its specific gravity is 1·5277. It is neither combustible

nor a supporter of combustion, except in the case of potassium, which, when heated in it, readily takes fire, and burns. It extinguishes most burning bodies when introduced into it in the ignited condition. Some years since, Dr. Faraday succeeded in condensing it into a liquid form; and lately it has been announced that a French chemist has solidified it.

Characteristic tests.—It is distinguished from other gases by being incombustible, and a non-supporter of combustion (except in the case just mentioned), and by its precipitating the solutions of lime or barytes white, the precipitate being soluble in acetic acid. The carbonates effervesce on the addition of hydrochloric acid.

Composition.—By burning charcoal in 1 volume, or 16 parts by weight, of oxygen gas, we obtain 1 volume, or 22 parts by weight, of carbonic acid.

Before combustion.		Result.
oxygen = 16	& carbon = 6	carbonic acid = 22

Hence this acid is composed of—

1 atom of carbon	=	6
2 atoms of oxygen	=	16
1 atom of carbonic acid ..		22

Solution of carbonic acid.—At the ordinary temperature and pressure of the air, one volume of water absorbs one volume of gas; and by doubling the pressure the quantity of gas absorbed is doubled, and so on for other degrees of force. The bottled soda water of the shops is usually only a solution of this gas in water; but some manufacturers add soda to the water before they condense the gas in it.

Physiological effects.—These vary according to the part of the body to which the acid is applied.

(*a.*) *Inhaled*, it acts as a positively narcotic poison. In the pure state it excites spasm of the glottis; but when mixed with atmospheric air, it causes a sensation of tightness at the chest, uneasiness, giddiness, loss of muscular power, insensibility, and stertorous breathing, sometimes accompanied with convulsions or delirium. That it is a positive and not a negative poison, as Nysten and others have asserted, seems proved from two facts: 1st, that an atmosphere composed of 79 parts of carbonic acid, and 21 of oxygen, acts as a poison, although there is as much oxgen present as there is in common atmospheric air; 2dly, that one bronchial tube of the land tortoise may be tied, without any serious injury to the animal; but if, instead of tying it, the animal be made to inhale carbonic acid gas by it, death takes place in a few hours.

(*b.*) Applied *externally*, it acts as an irritant. Thus it excites pain, redness, and a flow of tears, when brought in contact with the *conjunctiva*. Applied to the *skin*, care being taken that it be not respired, it excites a sensation of warmth, and pricking, or tingling, sometimes accompanied by pain, increased frequency of the pulse, sweating, and excitement of the nervous system.

(*c.*) Taken into the *stomach*, dissolved in water, or in the form of effervescing draughts, it allays thirst, and diminishes preternatural heat, thus acting like the other dilute acids. If it be evolved in the stomach, it distends this viscus, excites eructations, and checks both nausea and vomiting. It appears to promote the secretions of the alimentary tube, to assist the digestive process, to allay irritation, and to act as a refreshing and exhilarating substance. It is said to be diuretic and diaphoretic. Wöhler and Stehberger expressly state that the use of carbonic acid did not increase the quantity of this substance in the urine. When drunk too quickly, and in large quantity, water impregnated with this gas has been known to excite giddiness and intoxication; and it is probable that champagne is indebted to this substance for part of its intoxicating powers.

(*d.*) *On dead animal matter* it acts as an antiseptic.

Uses.—(*a.*) *When inhaled.*—In some diseases of the lungs, particularly phthisis, it has been proposed to mix carbonic acid gas with the atmospheric air breathed by the patient, with the view of lessening the stimulant influence of the oxygen; and it is said to have had the effect of diminishing the quantity of matter expectorated, and of improving its quality, while at the same time it relieved the hectic symptoms. It is not at all unlikely that temporary relief might be gained by its employment; but difficulty is experienced in the mode of applying it. Of course, to be beneficial, it ought to be constantly inspired. Temporarily it is readily inhaled, by generating it in a large bottle or jar, and breathing it by means of a tube; but for its continued use, the only method that can be employed is to evolve the acid in the patient's chamber. In some parts of the continent a popular remedy for consumption is a residence in rooms or houses inhabited by cows; and the asserted beneficial effects are supposed to be in part attributable to the carbonic acid gas with which the chamber is impregnated; but, says Vogt, in his *Lehr-*

buch der Pharmakodynamik, "we must not overlook the humid, mild, balsamic vapour, with which the air of cow-houses is commonly filled*."

(*b.*) *Taken into the stomach*, carbonic acid is a most valuable remedy for checking vomiting, and diminishing irritable conditions of this viscus. The best mode of exhibiting it is, I believe, in the form of an effervescing draught, composed of citric acid and bi-carbonate of potash. In fever, you will find it an excellent refrigerant; especially serviceable in those cases which are accompanied by a disordered condition of the digestive organs. In that form of lithiasis attended with a white or phosphatic deposit in the urine, water, impregnated with carbonic acid, may be taken with advantage; but in this case you cannot substitute the common effervescing draught, (made of a vegetable acid, and a carbonated alkali) since this communicates an alkaline property to the urine, as I shall have occasion hereafter to explain, when speaking of the alkalies and their salts.

(*c.*) *Clysters of carbonic acid gas* have been employed in certain affections of the rectum and colon,—for example, ulceration of the rectum, especially when of that kind commonly denominated cancerous.

(*d.*) *A stream of carbonic acid gas* has been applied to the *uterus* with great benefit, in a painful condition of that viscus. [See p. 134 of the present volume.]

(*e.*) *Applied to the skin,* care being taken that the gas is not inhaled, it is employed either in its gaseous form, or dissolved in water. It is, of course, adapted to those cases where it is desirable to excite the vascular system, especially of the skin, and to cause perspiration; while, on the other hand, it is objectionable in inflammatory cases. In chlorosis, amenorrhœa, dyspepsia, hysteria, scrofula, &c., it has been found useful.

(*f.*) It has been applied to the surface of cancerous and other ulcers, to allay pain, improve the quality of the secretions, or to check sloughing. It is readily administered by means of a tube connected with a bottle generating the gas. In this case you had better procure it by the action of dilute sulphuric acid on marble, for if you employ hydrochloric acid, the gas requires washing, to remove any of this acid which may pass over with it. Or it may be used in the form of solution, in which case the bottled soda-water may be employed.

Poisoning.—As carbonic acid gas, when taken into the lungs, is a powerful poison, and as it is a substance which may be frequently met with, I think it right to point out under what circumstances you may expect to find it, and the best method of treating patients labouring under its effects.

In the first place, as to the *sources* of it: I have already alluded to some instances of its natural evolution from the earth; its development in wells and mines. It is produced by organized beings, plants as well as animals, and, therefore, is met with in greenhouses, especially during the night, when it is given out by vegetables. In crowded rooms, with imperfect ventilation, accidents have sometimes happened, from the accumulated carbonic acid. It is developed by fermentation, and hence the danger of descending into brewers' vats; it is evolved by the burning of limestone (carbonate of lime) at lime kilns, and by the combustion of charcoal and carbonaceous gases, as coal gas, and the fire damp of coal mines.

The best *treatment* is the following:—remove the patient immediately into the open air, and place him on his back with the head somewhat elevated. Produce artificial respiration in the way I have on a previous occasion described, namely, by pressing down the ribs, and forcing up the diaphragm, and then suddenly removing the pressure. Dash cold water over the body, and abstract a small quantity of blood either by venæsection or cupping. Stimulants of various kinds may be em-

* I am indebted to Mr. Steinhaeuser (a very intelligent pupil of mine), a native of Saxony, for the following note on residence in cow-houses, as a remedial agent in diseases of the lungs:—"In Germany, the balsamic air of cow-sheds is commonly recommended as a preventive in suspected pulmonary disease, or as a means of prolonging life in confirmed phthisis. Although this latter disease is comparatively of rare occurrence in Saxony, yet several cases have fallen under my own observation, in which this plan of treatment was adopted. The mode of effecting it has varied according to circumstances: in some cases the patient has merely retired from a crowded town to a farm-house; in others, the sitting and bed rooms have actually been converted into residences for cows. Of the former, I have known several instances where patients have been greatly benefitted by sleeping in apartments built over cow-stalls; and this, I should say, is the most usual plan adopted. Of the latter I can only record one case, which is somewhat remarkable. It is that of the late Prince Putiati, a Russian exile, resident in the vicinity of Dresden, and well known there on account of his eccentricities. His young, beautiful, and only daughter, the Countess ———, being affected with this destructive malady (phthisis), to which she eventually fell a victim, the warm air of cow-sheds was recommended by her physicians, as a mode of prolonging her life. The Prince ordered the lower part of a wing of his magnificent but curiously constructed mansion (Schachwitz, to be converted into a cow-stable; and the elegantly furnished sitting and sleeping apartments of his daughter were so arranged, that she was actually in the same room with the cattle, from which she was merely separated by a low partition." Of the eccentricities of the Prince I may just add two illustrations: his boots were made of tin, to guard against the possibility of his legs being bitten by mad dogs, while his umbrella was attached to his shoulder by a hook, and was glazed, that is, had what we may call a sky-light in it.—J. P.

ployed either internally by the stomach, or in the form of frictions, or inhalations (as of ammonia, weak chlorine, &c.).

A word or two as to the means of guarding against the inhalation of carbonic acid gas. It sometimes happens that you may be required to enter a room or other place containing this gas, but which may have sufficient oxygen present to support life, if the noxious gas can be got rid of. Now it is important to know how to strain the air, so as to stop the acid while the oxygen is allowed to enter the lungs. The principle is simple enough; namely, to breathe through an alkaline or even aqueous solution. Thus, dip a handkerchief or piece of flannel in a weak solution of potash or of lime, or even in common water, and apply this over the mouth and nose. If at hand, *Mr. Roberts's fire-hood* may be regarded as the best kind of apparatus. It consists of a leathern hood fitting over the head, with glass eyes, and a breathing tube or pipe, at the end of which is a piece of sponge dipped in cream of lime; so that all the air inhaled has to pass through the lime, which stops the carbonic acid.

Yeast Poultice.

As the efficacy of the *yeast poultice* is usually supposed to depend on the carbonic acid gas which is extracted from it, this, I conceive, will be the most convenient place for noticing it.

Preparation.—In the London Pharmacopœia it is ordered to be prepared by mixing a pound of *flour* with half a pint of *yeast*, and applying a gentle heat until the mixture begins to rise. But this is not the method invariably followed. Thus, you may substitute the *grounds of stale beer* for the yeast, and a mixture of oatmeal (or of potatoes) and linseed meal for the flour.

Yeast, or the *fermentum cerevisiæ*, somewhat approaches gluten in its nature; it is a viscid substance, composed, according to F. Marcet, of—

Carbon	30·5
Oxygen	57·4
Nitrogen	7·6
Hydrogen	4·5
	100·0

I suspect, however, there is some error in this analysis, the quantity of oxygen being too large. I quote the analysis from Gmelin's *Handbuch der Chemie*. The most characteristic property of yeast is that of exciting fermentation. Hence its use in this preparation. Now one of the products of the process of fermentation is carbonic acid gas, which is supposed to be the active ingredient of this poultice.

Effects and Uses.—It is applied to fœtid and sloughing sores, as an antiseptic and stimulant: it destroys the fœtor, often checks the sloughing, and assists the separation of the dead part. I have frequently heard patients complain of the great pain it causes.

WATER.

History.—By the ancients, water was regarded as an elementary substance, and as a constituent of most other bodies. This opinion, apparently supported by numerous facts, was held until the middle of the last century, when the Hon. Mr. Cavendish proved that this liquid was a compound of two other bodies—oxygen and hydrogen. It is, however, only doing justice to Mr. Watt, to say that he had previously inferred that this was the composition of water, but was deterred from publishing his opinion in consequence of some of Dr. Priestley's experiments being apparently opposed to it.

Native State.—(*a.*) *In the inorganized kingdom.*—In the *atmosphere*, water exists in two states—either as a vapour, which is supposed to communicate the blue colour to the sky, or in a vesicular form, constituting the clouds. Three-fourths of the whole *surface of the globe* are aqueous; and the average depth of the ocean is calculated at between two or three miles. Now as the average height of dry land above the surface of the sea is less than two miles, it is evident that if the present dry land were distributed over the bottom of the ocean, the surface of the globe would present a mass of waters a mile in depth. Water is also found in some minerals in a solid state, constituting what are called *hydrates*.

(*b.*) *In the organized kingdom.*—Water is an essential constituent of vegetables and animals. The only exception that can be urged against this statement, is, that some *musci*, and also some *polygastrica*, may be dried without losing their vitality, although, while in this state, they give no sign of life, but may be restored by moistening them.

Preparation of pure water.—Absolutely pure water may be procured by combining its elements; but for all practical purposes, it is obtained pure by the distillation of common water. The purest natural water is snow and rain water; then follow river, spring, and well waters.

Properties of water.—Pure water has the following properties:—At ordinary temperatures it is a transparent liquid, usually described as being both odourless and colourless; but it is well known that the camel can scent water at a considerable distance, so that to this animal it is odorous; and as regards its colour, we know that all large masses of water have a

bluish-green colour, though this is usually said to arise from foreign matters. When submitted to a compressing force equal to 30,000lbs. on the square inch, 14 volumes of this liquid are condensed into 13 volumes; so that it is elastic. At the temperature of 60° Fahr. it is about 814 times heavier than atmospheric air: but being the standard to which the gravities of solids and liquids are referred, its specific weight is usually said to be 1·. When cooled below 32°, it crystallizes, and forms ice; the fundamental form of whose crystal is the rhombohedron. It evaporates at all temperatures, but at 212° boils, and is converted into steam. It unites with both acids and bases, but without destroying their acid or basic properties. Thus the crystallized vegetable acids, tartaric, citric, and oxalic, are atomic combinations of water with acids. Potassa fusa and slacked lime may be instanced as compounds of water and basic substances: these are called *hydrates*. It is a chemical constituent of some crystallised salts; for example, alum, sulphate of soda, and sulphate of magnesia. It rapidly absorbs some gases—as fluoride of boron, ammonia, &c. It is neither combustible nor a supporter of combustion.

Characteristics.—In the liquid state, it is recognized by being tasteless, and neither combustible nor a supporter of combustion: it is miscible with alcohol, but not with the fixed oils; if potassium be thrown on it in the open air, the metal takes fire. Lastly, water may be decomposed into oxygen and hydrogen by the galvanic agency. The most delicate test of aqueous vapour in any gas, is fluoride of boron (commonly called fluoboric acid gas), which produces white fumes with it.

Composition.—The composition of water is determined both by analysis and synthesis. If this liquid be submitted to the influence of a galvanic battery, it is decomposed into two gases—namely, one volume of oxygen, and two volumes of hydrogen gases. These gases, in the proportions just mentioned, may be made to recombine by heat, electricity, or spongy platinum; and water is the result.

Atomic composition.			Per centage composition.
1 atom of oxygen..	= 8	..	88·8
1 atom of hydrogen	= 1	..	11·1
1 atom of water....	9		99·9

It is composed of 1 volume of hydrogen, and half a volume of oxygen, which unite and condense into 1 volume of aqueous vapour.

Constituents.		Results.
Hydr. = 1	Oxyg. = 8	Aqueous vapour = 9

Tests of its purity.—Pure distilled water ought to remain unchanged on the addition of any of the following substances:—solutions of the alkalies, lime water, oxalic acid, the barytic salts, nitrate of silver, and solution of soap. If any turbidness, milkiness, or precipitate, be occasioned by any one of the above, we may infer the existence of some impurity in the water.

Physiological effects and uses.—In a *dietetical* point of view, water serves at least three important purposes in the animal economy; namely, it repairs the loss of the aqueous part of the blood, caused by the action of the secreting and exhaling organs; secondly, it is a solvent of various alimentary substances, and, therefore, assists the stomach in the act of digestion, though, if taken in very large quantities, it may have an opposite effect, by diluting the gastric juice; thirdly, it is probably a nutritive agent, that is, it assists in the formation of the solid parts of the body.

In a *therapeutical* point of view, we employ it for several purposes—thus, sometimes as a medium for communicating or abstracting heat from the body; sometimes as a diluent, as in poisoning by acrid substances; sometimes to promote the activity of the exhaling or secreting organs; lastly, at other times it seems useful by its impulse, or pressure. In some of the modes of employing it remedially we attain more than one of these objects; thus in cold affusion the water acts both by its temperature and impulse.

1. *Effects of ice, snow, and ice cold water.*—The temperature of these agents is not higher than 32° F. When brought in contact with a living part, they produce two series of effects—the first of which may be denominated *direct*, *primary*, or *immediate*; while the second may be termed *indirect*, *secondary*, or *mediate*, since they are developed by the vital actions merely, after the cold agent has ceased to abstract heat. (*a.*) *Of the primary effect*.—When ice is applied to the body, it abstracts heat, causes pain, reduces the volume of the part, and diminishes vital action; and if applied for a sufficient period occasions mortification,—an effect which is hastened by the previously weakened condition of the part. If applied to a large surface of the body, and for a sufficient length of time, the

processes of secretion, circulation, and respiration, are checked, and stupefaction, followed by death, ensues.

The primary effect of ice or snow applied *externally* is much greater than when either of these agents is swallowed The reason of this will be obvious presently.

(*b*.) *Secondary effects.*—If, however, the application be of a temporary nature, more especially if the subject be young and robust, reaction follows the removal of the cold agent. The vascular action of the part is increased, the pulse becomes full and more frequent, and the animal heat is restored to its proper degree, or is even increased beyond its natural standard. These effects, more or less modified, are observed both from the internal and external employment of ice.

When taken *internally*, the sensation of cold which it produces is not so obvious as that occasioned by its external application (in consequence, probably, of the stomach being accustomed to the contact of cold substances); and the effect is more temporary, from the greater heat of the internal parts, by which the ice is sooner melted, and the resulting liquid quickly raised to the temperature of the body. When, however, it is taken in sufficient quantity, the effects are of the same general kind as those already described, namely, a sensation of cold in the epigastrium, sometimes attended with shivering; diminished frequency of pulse; temporary contraction of the alimentary canal; diminution of irritability, and of secretion. Employed in small quantities, these effects are not at all perceived, or are only momentary; and the second stage, or that of reaction, almost immediately follows. A feeling of warmth at the epigastrium soon succeeds that of cold, and this extends shortly over the whole body: the secretions of the alimentary canal, of the kidneys, and of the skin, are increased; and the circulation is accelerated. Sometimes these secondary effects are attended with those of a morbid character; thus inflammation of the stomach is occasionally brought on by the employment of ice.

Uses.—Sometimes we administer ice *internally*, for the purpose of obtaining its primary effects; thus, in *hæmorrhages* from the stomach, we use it for the purpose of causing contraction of the vessels of the gastric surface, and thereby of checking or stopping the sanguineous exhalation. So also in violent hæmorrhage from the lungs or nose, ice-cold water, taken into the stomach, has been beneficial. In most cases, however, we use it on account of its secondary effects. Thus, in relaxed and atonic conditions of the stomach—in dyspepsia and cardialgia—to check vomiting—and to allay spasmodic pain. In those forms of fever denominated putrid, the internal use of small quantities of ice is sometimes beneficial.

Ice is sometimes employed, *externally*, to check hæmorrhage, more especially when the bleeding vessel cannot be easily got at and tied. Thus after operations about the rectum (more especially for piles and fistula) hæmorrhage sometimes occurs to a most alarming extent; and in such cases our principal reliance must be on cold. In two instances that have fallen under my own observation, I believe the lives of the patients were preserved by the introduction of ice within the rectum. In many other cases of hæmorrhage, the external application of cold (either in the form of ice or ice-cold water) is exceedingly useful. Thus, applied to the chest in dangerous pulmonary hæmorrhage, to the abdomen in violent floodings, it is oftentimes most beneficial. In some of these cases, especially in uterine hæmorrhage, more benefit is obtained by pouring cold water from a height, than by the mere use of ice. I shall allude to this hereafter.

Pounded ice, tied up in a bladder, has been applied to *hernial tumors*, to diminish their size and facilitate their reduction; but notwithstanding that the practice has the sanction and recommendation of Sir Astley Cooper, it is, I believe, rarely followed, not having been found successful; and if too long continued, may cause gangrene. In this, as well as in other cases where ice or snow cannot be procured, you may substitute a freezing mixture. For this purpose, five ounces of muriate of ammonia, five ounces of nitre, and a pint of water, are to be placed in a bladder, and applied to the part. Ice has also been applied in *prolapsus* of the rectum or vagina, when inflammation has come on which threatens mortification.

In *inflammation of the brain*, ice, pounded and placed in a bladder, may be applied to the head with a very beneficial effect. In *fever* also, where there is great cerebral excitement, with a hot dry skin, I have seen it advantageously employed. In *apoplexy* also it might be useful. In the *retention of urine* to which old persons are liable, ice-cold water applied to the hypogastrium is sometimes very effective, causing the evacuation of this secretion.

In the above-mentioned local uses of ice, we either apply it directly to the part, or enclose it in a bladder: the latter is to be preferred, since the patient is not wetted with the melted water, while the effect is less violent.

In the last place, I must notice the employment of ice or snow in the form of

friction. Whenever used in this way, the ultimate object in view is the production of the secondary effects, or those which constitute the stage of reaction. Thus this practice has been resorted to in diminished sensibility of the skin, in the rheumatism or gout of old and enfeebled persons, in order to produce excitement of the skin; but its most common use is as an application to parts injured by cold. The affection thus induced is called *pernio*, or the *chilblain*; and the parts which are thus affected are said to be *frost-bitten*. The feet, hands, tip of the nose, and pinna of the ear, are the organs most frequently attacked. Now, with the view of preventing the mortification and other ill consequences arising from the application of cold, you must most carefully avoid sudden changes of temperature. The frost-bitten part, or the chilblain, should be rubbed with snow or pounded ice, or bathed in ice-cold water, very gradually raising the temperature of the applications until the part acquires its natural heat.

The further consideration of the effects and uses of water must be left until our next lecture.

OBSERVATIONS ON THE HEART'S ACTION AND SOUNDS.

By Charles Cowan, M.D.

Notwithstanding all that has been done and written for the purpose of elucidating the mode of the heart's action, and the true causes of its sounds, no one can deny that the question continues to be involved in considerable difficulty, and that various contradictory hypotheses still find their respective supporters. Much research and anatomical ingenuity have been expended in unravelling the complicated structure of this important organ, leaving to our successors rather the proper application of the knowledge we possess, than space for much additional discovery. Its movements, so far at least as they can be studied by ocular inspection on the living, though mutilated animal, have been watched with scrupulous accuracy, and its sounds both in health and disease, so vigilantly inspected by but a lately appreciated sense, that we may almost despair of any very important novelty being detected by those who are continuing the investigation. There is, however, one department of the subject, which we think has not sufficiently arrested the attention of observers, viz. an accurate appreciation of the physical conformation of the cardiac cavities, as well as of their valvular appendages, and a strict association of these with the hydrostatic conditions of the circulation. Hypotheses have been set forward, with apparent facts for their basis, which, when impartially scrutinised, may be referred back for their origin to the very theory they are supposed to originate: conjectures have been founded upon experiments either wholly artificial and of more than questionable accuracy, or made on the living animal when the physiological integrity of the organ was seriously impaired: and when we reflect on the numerous elements of the problem attempted to be solved, and the difficulty of submitting them all to the test of rigorous demonstration, it must cease to be a matter of surprise that differences of opinion continue to prevail.

In the following observations we shall endeavour to direct attention to considerations which we believe are not without importance when analysing the possible causes of the heart's sounds, and we do so the more willingly, since we are satisfied that any suggestion we may offer will be impartially canvassed by those who are now engaged in the arduous task of untying the gordian knot of this anatomical and physiological puzzle.

The ingenious researches of M. Bouillaud, in his recent work on diseases of the heart, have first clearly pointed out the fact that the ventricular cavities consist of an auricular and vascular portion; the former immediately continuous with the auriculo-ventricular opening on either side, and the latter with the aorta and pulmonary arteries. We have repeatedly verified the reality of this description, both in the heart of man, the ox, and sheep; and our only surprise has been, that so palpable an arrangement could have been hitherto almost entirely overlooked*.

Let us briefly avail ourselves of M. Bouillaud's description. The cavity of

* To estimate the accuracy of the succeeding remarks, the student should have an opened healthy heart before him. The ventricular cavities should be exposed, by cutting through the aorta and pulmonary artery.

each ventricle, he says, is composed of two very distinct regions: in the right side, the pulmonary is united to the auricular by a kind of angle, the sinus of which is directed upwards. In the left, the aortic and auricular regions are parallel to one another, or nearly so, and take a vertical direction. They are separated by the right or anterior lamina of the bicuspid valve, and by two large fleshy columnæ, which, projecting in the interior of the left ventricle, rise by numerous fasciculi from the posterior paries; the one outwards, towards the junction of the anterior surface of the ventricle, with its posterior forming the left border of the heart; the other inwards, at the point of union of the posterior surface with the interventricular partition. It is below, backwards, and to the outside of this natural division, or bridge, that the auricular portion is placed, whereas the aortic region, larger than the other, is situated above, forwards, and inwards. These regions communicate with one another at the interval which separates the two voluminous columnæ mentioned.

From this arrangement it will be seen, in the first place, that the ventricular cavity, taken as a whole, is not placed (as the majority of descriptions would lead us to suppose) *immediately beneath* the auriculo-ventricular opening, but that the latter corresponds to only one, and that the smaller portion of the ventricles, which we have seen, in the left side, communicates with the aortic portion, between the two fleshy pillars, to which all the chordæ tendineæ are attached. The blood, therefore, in its descent from the auricle, cannot drop, as it were, into a vacuum previously formed for its reception by the active ventricular dyastole (Hope—Pigeaux), but must *gradually* pass downwards through the auricular portion, and from thence into the aortic portion, through the communicating space to which we have already alluded.

The theory, therefore, of one of the sounds depending on the shock of the blood against the apex, in its descent from the auricle, is, we think, refuted by an examination of these physical conditions. Besides, the blood must enter the ventricle from the first moment a vacuum begins to be formed; and it is evident that the portion of the ventricle which is most muscular, and consequently most powerfully contracted, will first expand, whether the cause of its expansion be either active or passive. Now the muscular structure of the ventricle is more developed in the auricular than in the aortic portion; the former, therefore, will first open, admitting the blood from the auricle, which from thence will successively occupy the remaining portions of the cavity. The idea of the ventricle being *empty and dilated*, for however short a moment of time, cannot, we think, be regarded as even possible; since the slightest augmentation of the cavity after the completion of the diastole, must necessarily involve a proportionate descent of the blood from the auricle; the valves presenting no resistance whatever in a downwards direction. The conditions of a shut cavity are, in fact, such that we do not hesitate to say that the ventricular diastole *could* not take place, if the ingress of the blood were impossible; the latter follows the augmentation of the cavity in the direction and in the manner we have described, and the ventricle is successively filled, without that shock and agitation of the fluid which is generally believed to take place at the moment to which we are referring. We need not, therefore, be surprised if no *sound* is generated by the descent of the blood into the ventricle, this fluid maintaining a constant and intimate relation with the gradually expanding walls of the cavity. All contrary hypotheses involve a want of this correspondence between the descending fluid and the dimensions of the cavity it is filling—a want, we believe, physically impossible, and which we could not conceive to exist without materially interfering with the regularity and efficiency of the heart's action.

An attentive examination of the ventricles, particularly of the left, will prove that the act of contraction almost obliterates the auricular portion of the cavity, and that the region corresponding to the sigmoid valves is conical in its form, smooth in its surface, and continuous with the calibre of the aorta; into which, therefore, the blood is propelled in a direct and equable manner, without those conflicting and counteracting currents, those violent molecular collisions, on which Dr. Hope and others have so much insisted.

Another important consideration, when analysing the heart's action, is the fact that at no one moment is there an empty

space, either in the cavities of this organ or in the vessels communicating with them; the line of blood being invariably unbroken, with the exception of the temporary intervention of the valves. It is true that all conceivable variations in the relative amount of fluid in the different cavities alternately exist, but this increase or decrease is invariably accompanied with corresponding variations in the containing parietes. Both theory and observation prove that the heart, by contracting, never expels the whole of its contents, the exit of the latter being uniformly opposed by the resistance of the fluid which is without; and the idea of the blood, either from the auricles or ventricles, passing into successively emptied spaces, would, as we before remarked, not only violate physical conditions, and involve a perpetual waste of power, but be irreconcileable with the undoubtedly constant, though regularly accelerated, progress of the circulating fluid.

The blood from the pulmonary veins, is, in a state of health, *perpetually* entering the auricular cavity; for during the moment of systole its progress cannot be materially interrupted, both on account of the superior dimensions of the ventricular opening, contrasted with the pulmonary orifices, from the more favourable direction of the former for the effects of gravitation, and still more in consequence of the active dilatation of the ventricle itself, which forces, as it were, a particular direction upon the current, and acts more or less on the contents of the veins, as well as on those of the auricle. It is also evident, that the fresh quantity of blood propelled by each ventricular systole into the aorta, is not simply projected forwards, as would necessarily be the case were that vessel in the condition of an unyielding and empty tube, but it also re-expands the collapsing arterial tunics, by forming a sudden increase to their previous contents; thus exciting their elasticity, by which the force originally impressed by the ventricular contraction is perpetuated, and a continuous current is sustained by the reaction of the vascular parietes on the gradually diminishing fluid, until a fresh impulse and supply renew the original conditions, and the same operation is repeated. These reflections are equally applicable to the right side of the heart and its corresponding vessels; we may, therefore, safely conclude that the vascular and cardiac parietes are at all times in direct contact with their contents, on the same principles that the pulmonary and costal pleura never cease to be approximated, notwithstanding the changes which are continually taking place in the volume of the lungs.

Let us now apply these and other considerations to the action of the valves attached to the auriculo-ventricular openings. They are generally described as membranous laminæ, hanging loosely in the cavity of the ventricles, which, during the systole of the latter, are mechanically thrown upwards by the pressure of the blood; their retroversion into the auricles being impeded by the tendinous filaments attached to their edges. There are, however, several circumstances connected with the physical conformation of the heart, in a state of health, rendering, we think, this generally adopted mode of describing the action of the valves both vague and unsatisfactory. In the first place, we have shown that the auriculo-ventricular opening corresponds to the smaller or auricular portion of the ventricular cavity, and that during the systole of the latter, this region is almost obliterated; the opening itself is in consequence diminished, becomes nearly excluded from the aortic portion of the cavity, from which it is, in fact, separated by the anterior lamina of the bicuspid valve. In the second place, the two powerful muscular columnæ, to which all the chordæ tendineæ are attached, contract in common with the walls of the ventricle itself, and, from the radiated nature of their connexion with the valves, the latter are necessarily pulled downwards and inwards; their edges approximating to a common centre, and the whole forming the figure of an inverted cone, whose apex corresponds to the auricular portion of the ventricle. The valves are therefore *muscularly tightened* from the first moment of ventricular contraction; they are every where raised from the muscular parietes on which they passively repose during the systole, and their functions are completed by the fluid pressure in the ventricle bringing a greater or less portion of their upper surfaces into immediate and accurate apposition. This is very different from the usually received opinion of their being mechanically flapped upwards by the blood, and their progress suddenly

arrested by the limits of the chordæ tendineæ; an operation purely mechanical, sudden, and abrupt in its effects, and which would inevitably strongly react on the blood in the auricle, where we should expect it to produce venous regurgitation; as is actually the case when extensive dilatation occasions unnatural distension of the valvular surface*.

On the other hand, the mode in which we have supposed the valves to execute their functions is regular and uniform, produces no agitation or shock on the blood, and cannot, we think, be productive of sound in any way distinct from what results from the contraction of the muscular fibres to which the chordæ tendineæ are attached,—a sound which, if existing, can only form a part of, and must necessarily be confounded with, what results from the contraction of the ventricle as a whole. The strain upon the tendons attached to the valves, it must be recollected, is gradual, proportionate to the force and duration of the muscular contraction, and would take place in an empty as well as a full heart, minus the force exerted by the compressed fluid, which we have shown, by reference to the relations of the auriculo-ventricular opening to the aortic portion of the cavity, can only be actively exerted on a very small portion of the valves.

The hypothesis, therefore, that the first sound of the heart (Bouillaud, Rouannet, &c.) depends on the reaction of the blood on the mitral and biscuspid valves, is, we think, but very partially, if at all, correct, these valves being principally tightened by the muscular contraction, which, with the exception of instances of extreme dilatation, is never instantaneous. In the latter case, where the action of the heart is sudden, though weak, it is possible that the equally sudden tension of the tendinous attachments of the valves, considered in connexion with the increased surface exposed to the action of the fluid, may be the source of some trifling addition to the resulting sound.

It should also be remembered that the valves, when functionally active, are in contact with the blood both above and below; and that when driven upwards or downwards, the retiring surface never corresponds to an empty space, but is forcing before it a greater or less quantity of fluid, and they are therefore not favourably situated for the production of sonorous vibrations.

M. Bouillaud considers that M. Rouannet has shown himself somewhat too exclusive when ascribing the first sound *solely* to the play of the mitral and bicuspid valves, and thinks that we should take into the account the *sudden projection* of the sigmoid valves against the aorta and pulmonary artery. Now this imaginary cause of sound could only be efficient on the supposition that the space immediately above the valves was unoccupied, whereas we think that the preceding reflections have tended to prove that the interval between their upper surfaces and the arterial parietes is filled by the blood in common with every other portion of the cavity, and the valves, when thrown upwards by the passage of the ventricular contents, have first to expel the portion of fluid separating them from the artery, thus rendering their contact with the latter necessarily gradual, and in proportion unfavourable to the production of sound. The same reasoning will also apply to the supposition of this sagacious observer, of sound being produced by the sudden striking of the mitral and bicuspid valves against each other; for, as in the preceding example, the interval between these surfaces is occupied with blood until the moment of contact, while the fluid displaced by their approach retires into a full though distensible space, and offers throughout a certain resistance, which is opposed to the idea of sudden and abrupt collision. Indeed, under any circumstances, the sudden contact of membranous laminæ like the valves, immersed in a fluid, appears to us utterly inadequate for the production of appreciable sonorous vibrations.

The analogy, which some have strongly insisted upon, between the mitral and bicuspid valves and those of pneumatic or hydraulic pumps, is, we think, at best, very incomplete, if not wholly illusory. The solid structure of the latter would alone, where a question of sound is at issue, form a glaring and

* The accommodating power of the valves to the varying dimensions of the auriculo-ventricular opening, may be easily demonstrated by an examination of their physical structure, and is quite in harmony with the explanation we have given of their action; since the portion of the inverted cone which is compressed, may diminish with the increasing space, until all contact ceases, and the function of the valve becomes impossible.

essential distinction. Their play is also arrested by materials more solid and more capable of sonorous vibrations than the valves themselves; they are closed by the reaction of the fluid, are wholly unconnected with the passive parietes of the cavity they temporarily limit,—conditions which forbid any thing like a just and accurate comparison with the membranous and muscularly attached valves of the heart.

On the other hand, the analogy is in some of its leading features capable of being maintained with regard to the sigmoid valves; and it is still further supported by the results, viz. the production of a sound recognized to be valvular in its character by all.

We have thus successively directed attention to the form of the ventricular cavities, to their division into an auricular and vascular portion, to the respective relations of these to the auriculo-ventricular opening, to the hydrostatic conditions of the heart and large vessels, to the structure and mode of acting of the mitral and biscuspid valves, and, we hope, satisfied the mind that a correct estimate of the physical conditions, regulating both the heart and its contents, is of primary importance in any attempt we may engage in to elucidate either its action or its sounds; and, we think, proved that in some of the hypotheses hitherto advanced, these conditions have not been sufficiently attended to.

We have also successively excluded the descent of the blood from the auricle into the ventricle, the agency of conflicting currents and molecular collisions, and the shock of the blood either against the apex or larger vessels, as causes of sonorous vibrations; and by the method of exclusion have reduced ourselves to the admission, that the first sound is principally, if not wholly, produced by the contraction of the muscular parietes of the ventricles.

The fact of sound being developed by muscular contraction, was proved by the ingenious researches of Dr. Wollaston and others; and attempts to make this cause active in the production of the cardiac sounds may be traced in the writings of Harvey, Senac, Haller, Bichat, Corvisart, Laennec, &c.; but to Dr. Williams is justly due the credit of having made a scientific application of the fact, and of founding his investigations upon a careful and sagacious examination of the heart's form, functions, and contents. We cannot help thinking that this view of a long-debated question will ultimately prevail, when names shall be disassociated from facts; but while expressing our individual opinion, we are not forgetful of our liability to err; and the intention of the preceding observations has not been to prejudge a confessedly difficult question, but to fix the attention of observers upon certain data of the problem which cannot be safely omitted in our efforts to attain its satisfactory solution.

An experiment illustrative of some of the preceding statements is the following:—Immerse an Indian rubber bottle, about the size of the left ventricle, and with a proportionate orifice, under water, and supply the contracting power of the heart by external pressure with the stethoscope, applied at the same time to the ear. It will be found that the most sudden and forcible expulsion of the contents will fail to produce any appreciable sound depending on the compressed and rapidly ejected fluid, but whatever is heard may be distinctly traced either to the agitation on the surface of the water in the reservoir, or to the Indian rubber itself. Indeed, this last source of sound is equally active when the bottle is compressed in air, and has evidently no other origin than the parietes themselves. The elastic property of the bottle may very well represent the active dilatation of the ventricle, on whatever cause it may really depend; and if compressed under water, and allowed suddenly to expand, by quickly returning the stethoscope (contact being always preserved) *no sound* indicates the entrance of the external fluid; there is no rushing, or shock, or agitation, appreciable by the ear, and the diastole, in this instance, is certainly quite as sudden as that of the ventricles. The absence of sound, as in the case of the heart, depends upon there never being, at any moment, a space unoccupied by fluid, the entrance of the latter exactly accompanying the dilating walls of the cavity, the rapidity of whose diastole is wholly regulated by the greater or less size of the communicating orifice. When the opening is artificially closed, the elasticity of the bottle, though considerable, is incapable of producing the diastole, which can only take place in proportion as

the consequent empty space becomes filled by air or fluid. The entrance of the latter may be said rather to accompany than follow the expanding parietes. If a small quantity of air be retained in the bottle, both the entrance and exit of the fluid generate sounds. We are immediately sensible of agitation, bubbling, and conflicting currents, which persist while any air remains, but entirely cease when the latter is expelled, and fluid contact restored. We have already insisted on the application of these facts to the heart's action and sounds, and need not again revert to them.

Bath, March 5th 1836.

CASE OF

PARTIAL SPONTANEOUS HUMAN COMBUSTION,

WITHOUT ANY FATAL RESULT.

By James Overton, M.D.
Of Tenessee.

The subject of the following case is a gentleman about 35 years of age, middle size, light hair, hazel eyes, sanguineo-lymphatic temperament, of habits entirely temperate in the use of stimulating drinks of any kind, fermented or alcoholic, with a constitution considerably enfeebled from long and zealous devotion to the sedentary and exhausting labour of scientific investigation. In early life he was very subject to derangements in the functions of the stomach and bowels; and at the present time suffers frequently from different modifications of these maladies, as costiveness, occasional diarrhœa, acidity of the stomach, heart-burn, &c. &c., with their usual train of sympathetic affections, involving parts of the organism at a distance from the primary seats of diseases into a participation of their suffering.

At the time of the occurrence of the accident, he was afflicted with acidity of the stomach, and by an unusual and irritating quantity of the matter of urea in the secretion of the kidneys; for the relief of which he was in the habitual use of aperients, antacids, &c.

Mr. H., Professor of Mathematics in the University of Nashville, was engaged as usual in his recitation room, in attendance upon the morning exercises of his class, till eleven o'clock in the forenoon. He then buttoned his surtout coat close around him, and walked briskly thus clothed to his residence, a distance of about three-fourths of a mile, taking exercise enough to produce a glow of warmth on the surface of the body, without inducing fatigue, but feeling at the same time his usual acidity of the stomach, for which he resolved to take some soda as a remedy within a short time. Having arrived at his lodging, he pulled off his over-coat and kindled a fire, by placing a few pieces of dry wood on three burning coals which he found in the fire-place, of the magnitude of two-inch cubes each; and immediately left the fire, and retired to a remote part of the room, and made his observations on the weight and temperature of the atmosphere, as indicated by the barometer and thermometer, which were suspended in that situation. He then took the dew-point by the thermometer. These operations, together with the registration of their results, occupied about thirty minutes. This having been accomplished, he went immediately into the open air, made observations on the hygrometer, and was beginning his observations upon the velocity and direction of the winds. He had been engaged in this latter process about ten minutes, his body all the while sheltered from the direct impression of the wind, when he felt a pain as if produced by the pulling of a hair, on the left leg, and which amounted in degree to a strong sensation. Upon applying his hand to the spot pained, the sensation suddenly increased, till it amounted in intensity to a feeling resembling the continued sting of a wasp or hornet. He then began to slap the part by repeated strokes with the open hand, during which time the pain continued to increase in intensity, so that he was forced to cry out from the severity of his suffering. Directing his eyes at this moment to the suffering part, he distinctly saw a light flame, of the extent at its base of a ten cent piece of coin, with a surface approaching to convexity, somewhat flattened at the top, and having a complexion which nearest resembles that of pure quicksilver. Of the accuracy in this latter feature in the appearance of the flame, Mr. H. is very confident, notwithstanding the unfavourable circumstances amidst which the observation must have been made. As soon as he perceived

the flame, he applied over it both his hands open, united at their edges, and closely impacted upon and around the burning surface. These means were employed by Mr. H. for the purpose of extinguishing the flame by the exclusion of the contact of the atmosphere, which he knew was necessary to the continuance of every combustion. The result was in conformity with the design; for the flame immediately went out.

As soon as the flame was extinguished, the pain began to abate in intensity, but still continued, and gave the sensation usually the effect of a slight application of heat or fire to the body, which induced him to seize his pantaloons with one of his hands, and to pinch them up in a conical form over the injured part of the leg, thereby to remove them from any contact with the skin below. This operation was continued for a minute or two, with the design of extinguishing any combustion which might be present in the substance of his apparel, but which was not visible at the time.

At the beginning of the accident the sensation of injury was confined to a spot of small diameter, and in its progress the pain was still restricted to this spot, increasing in intensity and depth to a considerable extent, but without much, if any, enlargement of the surface which it occupied at the beginning. A warmth was felt to a considerable distance around the spot primarily affected, but the sensation did not by any means amount in degree to the feeling of *pain*. This latter sensation was almost, if not entirely, confined to the narrow limits which bounded the seat of the first attack; and this sensation was no otherwise modified during the progress of the accident, than by its increasing intensity and deeper penetration into the muscles of the limb, which at its greatest degree seemed to sink an inch or more into the substance of the leg.

Believing the combustion to have been extinguished by the means just noticed, and the pain having greatly subsided, leaving only the feeling usually the effect of a slight burn, he untied and pulled up his pantaloons and drawers, for the purpose of ascertaining the condition of the part which had been the seat of his suffering. He found a surface on the outer and upper part of the left leg, reaching from the femoral end of the fibula in an oblique direction, towards the upper portion of the gastrocnemii muscles, about three-fourths of an inch in width, and three inches in length, denuded of the scarf-skin, and this membrane gathered into a roll at the lower edge of the abraded surface. The injury resembled very exactly in appearance an abrasion of the skin of like extent and depth, often the effect of slight mechanical violence, except that the surface of it was extremely *dry*, and had a complexion more livid than that of wounds of a similar extent produced by the action of mechanical causes.

The condition of the pantaloons and drawers was next carefully inspected. The left leg of the drawers, at a point exactly corresponding with the part of the leg which had suffered injury, and at a point accurately correspondent to the abraded surface, were burnt entirely through their substance. They were not in the slightest degree scorched beyond this limit, the combustion appearing to have stopt abruptly, without the least injury to any portion of the drawers, which had not been totally consumed by its action. The pantaloons were not burnt at all; but their inner surface opposite to, and in contact with, the burnt portion of the drawers, was slightly tinged by a thin frost-work of a dark yellow hue. The material of this colour, however, did not penetrate the texture of the pantaloons, which were made of broad cloth, but seemed to rest exclusively upon the extremities of the fibres of wool which were the materials of its fabric. The colouring matter was entirely scraped off with the edge of a penknife, without cutting the woolly fibres, after which there remained upon the garment no perceptible trace of the combustion with which they had been in contact. The pantaloons may be said with entire propriety to have suffered no injury of any kind from the accident. The drawers, which were composed of a mixture of silk and wool, were made tight and close at the ankle, and tied with tape over a pair of thick woollen socks, in such a manner as to prevent even the admission of air to the leg through their inferior opening. Considering the injury not to be of a serious character, Mr. H. bestowed upon its treatment no particular care or attention, but pursued his usual avoca-

tions within doors and in the open air, which was very cold, until the evening of the succeeding day. At this time the wound became inflamed and painful, and was dressed with a salve, into the composition of which the rosin of turpentine entered in considerable proportion. This treatment was continued for four or five days, during which time the wound presented the usual aspect of a burn from ordinary causes, except in its greater depth and more tardy progress towards cicatrization, which did not take place till after thirty-two days from the date of the infliction of the injury. The part of the ulcer which healed last was the point of the inception and intensity of the pain at the time of attack, and which point was evidently the seat of deeper injury than any other portion of the wounded surface.

About the fifth day after the accident, a physician was requested to take charge of the treatment, and the remedies employed were such chiefly as are usual in the treatment of burns from other causes, except that twice a week the surface of the ulcer was sprinkled over with calomel, and a dressing of simple cerate applied above it. In the space between the wound and the groin there was a considerable soreness of the integuments to the touch, which continued during the greatest violence of the effects of the accident, and then gradually subsided, The cicatrix is at this time, March 24th, entire; but its surface is unusually scabrous, and has a much more livid aspect than that of similar scars left after the infliction of burns from common causes. The dermis seems to have been less perfectly regenerated than is usual from burns produced by ordinary means, and the circulation through the part is manifestly impeded, apparently in consequence of atony of its vessels, to an extent far beyond any thing of a similar nature to be observed after common burns.

Since the wound has healed the health of the patient has been as perfect as usual; and while the wound continued open, his ordinary occupations were interrupted by a week's confinement only to his chamber. The accident occurred on the 5th of January of the present year, the day intensely cold, and the thermometer standing at only eight degrees above zero, sky clear and calm, and the barometrical admeasurement of the atmosphere being 29·248 inches.

Such is the history of the case of partial spontaneous combustion, which has recently occurred in this city. The facts have been stated as nearly as practicable in the words of the sufferer himself, and are consequently entitled to all the credit attributable to any statement of a similar character, which is or can be supplied by the annals of the profession*.

ACCIDENTAL POISONING OF THREE NEGROES WITH CANTHARIDES.

RECOVERY.

By James Maxwell, Esq.
Surgeon to the Annotto Bay Marine Hospital.

Three healthy robust negro men, on Fort Stewart Estate, had a bottle of rum brought to them by a young man who stole it from the overseer's house, in which six drachms of finely powdered cantharides had been macerated eight hours previously, to apply to the ringbone of a horse. The person who stole it tasted it, but not relishing the draught, carried it to his friends, and informed them that he had found a bottle of bitters, which the white people occasionally used, and as he was not fond of bitters, they might share it amongst them. This happened about 8 P. M. in fine moonlight, and it was divided as equally as possible, by each person putting the bottle to his head, and taking what he considered to be his share. R. Pollock had eaten a hearty supper before he partook of it; the other two drank it upon empty stomachs, and ate their supper immediately afterwards. Shortly after they complained of sharp lancinating pain of stomach, burning sensation of the throat, with great nausea, which increased, and in a couple of hours they were seized with violent retching; the contents of their stomachs were mixed with blood, mucus, and froth.

The kernels of six antidotes (*Feuiella cordifolia*) were boiled in a pint of water, and given to each by the black dispenser, which acted as an emetic.

17th.—I saw them early next morn-

---

* Amer. Journ. Med. Sciences, Nov. 1835.

ing. They are all complaining of excruciating burning pain in the region of the stomach; surface covered with cold clammy sweat, sense of constant burning of the throat, most intense at the top of the œsophagus, and descending along that passage to the stomach. There is great difficulty in swallowing, and to use the significant expression of one of them, his throat is on fire. There is great depression of the vital powers—they are incessantly moaning, and consider death to be inevitable; pulse accelerated about twenty beats in a minute, and rather weak. The breathing is not difficult, nor do they complain of any irritation of the urinary organs; no pain or tension of the abdomen: the bowels have not acted since they took the poison. The vomiting recurs at intervals, and they eject frothy mucus in great quantity, tinged with a vermilion colour. They are regularly salivated, spitting incessantly a mixture of mucus and saliva of a pink colour. The throat of each was examined, and found to be swollen; had an erysipelatous blush of inflammation, with turgid veins running across the fauces. To be perfectly satisfied that every particle of the powder was removed, I administered twenty grains of the sulp. of zinc to each, which acted instantaneously; they drank copiously of warm water, and after their stomachs were settled, three ounces of fine olive oil was given to each, which they retained. Enemata of the infusion of ochro, (*Hibiscus esculentus*,) with castor oil, ordered to be exhibited frequently, and the infusion to be drunk ad libitum.

The contents of the bottle were kept for my inspection; I had the dregs strained through blotting paper, dried in the sun, and ascertained that they had swallowed three drachms of the powder, and the whole of the rum, in which the cantharides had been macerated.

1 P.M.—They have had no recurrence of vomiting. One of them has had a copious alvine dejection, unmixed with blood. The symptoms continue the same as in the morning, with the exception of the stomach, which is less irritable. Two ounces of fine castor oil prescribed for each.

Evening visit.—The oil has operated on all; no blood has been passed by stool; they spit mucus and saliva tinged with blood incessantly. They complain of unremitting acute burning pain of stomach, with great difficulty of swallowing; thirst not urgent. Pulse of Pollock and Buchanan, 100. Mackintosh 80; no strangury. Blooded to eighteen ounces. Applic. emplast. lyttæ. regioni gastricæ. The enemata were directed to be given occasionally, and the ochro tea to be used as common drink.

18th.—R. Pollock's blood exhibited no buffy coat; oil operated freely, and since the emetic has had no irritation of stomach. There is neither blood in his stools nor urine, but he now complains of severe strangury, and the urine comes away in small quantities. The gastric symptoms are not so urgent; throat still painfully affected, inflamed and covered with coagulable lymph. He is constantly spitting a frothy matter mixed with blood; great thirst; no heat of skin; pulse 104, regular and full; tongue highly furred, with red edges. There is no fœtid smell of the breath; the gums are red and swollen, and he states the pain to be most severe at the top of the œsophagus, diminishing as it descends to the stomach.

George Buchanan.—Pain in the region of the stomach abated; throat very painful, with tumefaction of the tonsils, and relaxation of the uvula; the palate is suffused with a slight vermilion blush, deepest towards the fauces. The irritation of the bladder not so great as in Pollock; pulse 108, full; tongue furred and red at the edges; great difficulty of swallowing, with occasional eructations of sour frothy mucus, tinged red.

R. Mackintosh.—Gastric pain moderated; throat very painful, with difficulty of swallowing; tonsils swollen; uvula lengthened as in cases of catarrh; foul tongue with red edges; pulse 104; no fever; strangury very troublesome; continues to spit constantly, with an occasional eructation of frothy mucus, which he says is as sour as "lime-juice." The oil was repeated—fomentations to the region of the bladder, with opiate clysters, and warm bath.

19th.—Pollock.—Pain of stomach much relieved; throat swollen, and on the back part of the fauces there is an aphthous ulcer the size of a sixpence, covered with a whitish adherent crust; another of the same description on the side of the right tonsil. Sublingual

glands slightly inflamed and tumefied; gums red, with a copious secretion of saliva, which causes his mouth to stream as if he was under a course of mercury. Pulse 98, soft and full; strangury excessively severe; he passes his urine guttatim, and, to use his own expression, it burns him " like a pepper."

Mackintosh.—Describes the pain of stomach to be rather severe to-day; pulse 120, with thirst; no febrile heat; gums and inside of the mouth inflamed and ulcerated, and he says that he feels exactly the same as he did when lately salivated with mercury, only has no coppery taste in his mouth; throat still inflamed; difficulty of swallowing great; strangury troublesome.

Buchanan.—Feels better; throat still inflamed; pulse 100; completely salivated, with ulcerated gums; strangury much alleviated.

20th.—There is an amelioration of all the symptoms: the strangury has left Buchanan; the other two are still slightly affected with it; the salivation continues in all.

21st.—They are improving.

24th.—Strangury gone; salivation abating; throat and mouth getting better. From this time they gradually recovered, and in two weeks were perfectly well.

The recovery of these persons from the effects of a highly corrosive substance, may be considered a fortunate circumstance, and in a great measure may be attributed to the speedy ejectment of the poison from the stomach. Not less than a drachm of cantharides, mixed with about six ounces of rum, could have been taken by each of them, but as they filled their stomachs with their favourite supper meal, its effects were not so immediately palpable as it otherwise would have been. They admitted that the stolen liquor had rather a nauseous taste, but as it was given to them as bitters used by the white people, they shared the prize, and soon afterwards began to suspect that they had been imposed upon. The pain increased rapidly, but, conscious of their guilt, they were afraid to call for assistance till they could no longer conceal it, but so soon as severe vomiting commenced, they suspected that they had drank a poisonous liquid, became alarmed, and told the truth.

The antidote, a favourite remedy amongst negroes for all such accidents, was administered, and its over-dose acted as a powerful emetic, relieving the stomach of its entire contents. Not satisfied with what had been done previous to my arrival, I immediately gave an emetic, to ensure the complete ejectment of the poison, and directed large quantities of the bland mucilaginous infusion of ochro to be liberally used, with oil to sheath the coats of the stomach from the escharotic effects of the cantharides.

Magendie has warned us against exciting the activity of the absorbents by venesection, in cases of poisoning, and following the recommendation of that distinguished physiologist, I abstained from abstracting blood, till I had reason to think that the powdered cantharides were effectually removed by vomiting and purging. It was not till towards night, when the gastric symptoms assumed an alarming aspect, and threatened active inflammation, that I had recourse to the usual efficient means of subduing it. The throat was early affected with inflammation, and the red excoriated state of the tongue may have been occasioned by a few particles of the powder having lodged there.

It is a singular circumstance, that previous to venesection, not one of them had the least irritation of the urinary organs; but very soon afterwards they were seized with a very severe form of spasmodic strangury, attended by severe scalding, long before it could be presumed that the blisters could effect such a result.

It is well known to those conversant with negroes, how partial they are to blisters, for the most trifling ailments, and how little susceptible they are of strangury; for in ninety-nine cases out of a hundred, that highly painful affection is unknown amongst them from the absorption of blister-flies. It is reasonable, therefore, to infer, that the application of the blisters had little, if any, share in exciting the vesical irritation, but that the agency of the absorbents was increased by lessening the circulating fluids, so as to produce the phenomena in question.

I may here remark, how fallacious are all those agents, so confidently recommended for alleviating the excruciating sufferings from strangury. I never found camphor, either sprinkled on the blister, or given in large doses,

of the least utility. The only remedies which offer any positive relief in severe cases of strangury, are anodyne clysters, flannel wrung out in hot water, to which laudanum has been added and applied over the pubis, with the administration of an opiate, where circumstances will admit*."

CASE OF

DISLOCATION AND FRACTURE OF THE SPINE;

TERMINATING FAVOURABLY.

By Gardiner Dorrance, M.D.
Of Amherst, Massachusetts.

In this journal, for May, 1835, a case of fractured spine is reported, in which depression of the spinous process was removed by an operation. The case proved fatal; but the operator thinks an elevation of the depressed process furnishes the only hope for the patient, and therefore recommends it.

About six years since, Amos Marsh, of Sunderland, while at work in the woods, was struck by a falling tree, and bent to the ground. I saw him soon after he was removed to his house. I found him in bed, saying, that both his thighs were broken. Finding them straight and firm, I suspected loss of sensation in them from injury of the spinal cord. Turning him on his side, I found an angle at the eleventh dorsal vertebræ, of forty-five degrees.

It looked like so easy a thing to make the spine straight, that I could hardly resist the inclination to put it so; and the by-standers were impatient at my hesitation to do it. I supposed there was partial dislocation of the vertebræ, which any attempt at reduction would probably make a perfect one. I knew, too, that dislocation could not take place without fracture of the spinous or transverse process, and that loose spiculæ of bone would very possibly be driven into the spinal marrow, and cause instant death. A consulting physician, who saw the patient some hours after, was anxious to attempt a reduction; and when dissuaded from that, proposed cutting down and removing the broken and probably depressed fragments of bone. It was, however, concluded to trust the patient to nature, using bleeding and low diet, to prevent, as far as possible, inflammatory action in the injured part.

Mr. Marsh had for a number of weeks almost perfect paralysis of the lower limbs, and of the lower abdominal viscera. Urine was drawn off by the catheter, and the bowels moved by stimulating injections. By degrees, sensibility and mobility returned to the limbs, and the bladder and rectum resumed their functions. In four months the patient walked with crutches, and in six with a staff. In less than a year he resumed his trade, that of a cooper, and he now performs as much labour, sometimes in his shop, and sometimes in the field, as most men of his age. There is a stooping of his back, and a sideway motion to his gait. The vertebræ are not in place, though more so than at first, and I believe much more so than art could have placed them.

The palsy of the parts below the injury shows that the spinal marrow was compressed, either by displaced vertebræ, or by the depression of their spinous processes. Nature has by some means gradually removed the compression. In the hurry and agitation of such an accident, the physician wants some rule of practice to guide him. From the fatality or permanent paralysis of the lower extremities, which have attended all the cases I have known of, where reduction of dislocation or removal of depression have been attempted, I consider the favourable result in the case of Mr. Marsh may encourage us to wait and hope. The curative powers of nature are often greater than we are disposed to believe them*.

SPASMODIC ASTHMA:

WHETHER RELIEVED BY DESCENT IN A DIVING BELL.

To the Editor of the Medical Gazette.

Sir,

There was lately pointed out to me at Portsmouth, a man who has been engaged in raising various valuable stores out of vessels which have sunk in the

* Jamaica Physical Journal, May, 1835; and American Journal of Medical Sciences.

* Amer. Journ. Med. Sciences, March, 1835.

channels leading into the harbour; and a circumstance was related of him which has excited so much my curiosity, that I am anxious, through the medium of your valuable journal, to get at the particulars from some medical practitioner resident near the spot.

It appears that the man was originally a pilot, and from his childhood suffered from spasmodic asthma; but that since he commenced his present occupation, in fact after his third submarine trip, the disease has *totally* disappeared. Now that the disease was *bonâ fide* spasmodic asthma, Dr. Bree's disease, is the first fact that I wish clearly to ascertain; next, that after he had been three times immersed in the condensed atmosphere of the diving-bell, a complete remission of the symptoms ensued.

I need not offer any apology for troubling you; the least glimpse of anything which can mitigate so very disagreeable a disease is too important to be overlooked.—I am, sir,

Your obedient servant,

R. TEMPLETON.

Woolwich, March 22, 1836.

ANALYSES AND NOTICES OF BOOKS.

"L'Auteur se tue à allonger ce que le lecteur se tue a abréger."—D'ALEMBERT.

A Practical Essay on the History and Treatment of Beriberi. By Assistant-Surgeon JOHN GRANT MALCOLMSON, Madras Medical Establishment.

Essay on the Origin, Progress, and Treatment of Cholera; with Remarks on Berriberri and Diet. By JAMES BANKIER, M.D. of the Royal Navy, Madras. 1835.

BERIBERI, the very remarkable disease of which an account is given in the above essays, has for some years attracted a large share of attention from our brethren in India; except cholera, no malady has given rise to more difference of opinion either as to its pathology or its treatment. The former of the works before us contains by much the more full and satisfactory history of beriberi, Dr. Bankier having only appended some remarks upon this disease to a volume professedly upon cholera.

Mr. Malcolmson has both enjoyed extensive opportunities of investigation, and has brought to the task an intelligent and cultivated mind: his essay was printed by order of the government at Madras, and as a copy has by good fortune fallen into our hands, we are sure our readers will be glad to be put in possession of information which probably very few, if any of them, would otherwise be able to obtain. Nor let it be supposed that what follows relates only to a disease which is limited to tropical climates, and therefore cannot come under our observation in temperate regions;—cholera has shewn the fallacy of trusting to such grounds of exemption; besides which, beriberi bears a very close resemblance on the one hand to paralysis, and on the other to rheumatism; presenting as curious a subject of study and investigation as any we are acquainted with in the whole range of nosology.

Beriberi [or Berriberri] is attended by a peculiar affection of the lower extremities, sometimes acute and sometimes chronic—often extending to other parts, particularly the chest. The following is a general account of the symptoms:—

"It usually commences gradually, with a feeling of numbness, sense of weight and slight weakness and stiffness below the middle of the thighs, sometimes preceded by muscular pains. There is slight œdema of the feet and legs, especially along the tibiæ, often found to come on after the other symptoms. The walk is unsteady and tottering even when the patient is not aware of weakness in the limbs, which are occasionally tremulous; spasms occur in the calves and soles of the feet, sometimes becoming general, and occasionally shooting to the chest and larynx, obstructing respiration and speech. The want of power often rapidly increases to almost total palsy, especially of the extensor muscles, and, in a few cases, the patient after slight indisposition suddenly loses the use of his legs. Rigidity and various painful affections of the nerves accompany the paralytic symptoms; and there is sometimes pain along the spine, commonly at the two last lumbar vertebræ. In some cases the disease goes no further, and a cure is effected: but, more frequently, the numbness extends upwards towards the abdomen, there is general sense of lassitude and aversion to motion, and the

hands, arms, and chest, (and in a few cases even the neck and lips) are gradually benumbed. There is oppression and weight at præcordia, dyspnœa on slight exertion, diffused and irregular pulsation in the cardiac region, and the face and hands are puffy and œdematous. The patient is often found dead in bed, or sinks after several fainting fits or throbbings at the heart; or the œdema rapidly increases and extends up the trunk, violent dyspnœa and inability to lie down in bed comes on, with anxiety, cold sweats, cold extremities, rapid feeble pulse, urgent thirst, and partial suppression of urine. At the commencement the urine is always scanty, of a deep red colour, without cloud or sediment, and possessing very peculiar properties; in some old cases it becomes copious, turbid, and pale, with a large white deposit, and is passed, with pain, from an irritable bladder. The stomach is irritable in many bad cases, and pain and tenderness in the epigastrium is sometimes complained of; there is, in a few, pain in the abdomen, or a sense of heat is diffused over it and the chest. Effusion takes place into the chest, and more rarely into the abdomen, and there are now and then some signs of inflammation of the pleura or bronchi. In the early stage, the pulse may be full, hard, and frequent, or little altered; when the face is puffy, and there is weight and oppression at the præcordia, it is quick, often irregular, and usually small, although it is occasionally strong.

"Various dyspeptic symptoms occur; the bowels are often costive, the stools green and variously disordered, and the eyes are often tinged yellow. The skin is rather cold, unless there is pyrexia, which is often present in the evening. The disease is sometimes fatal in a few hours, but is often chronic, and in these, the patient is liable to sudden death, to rapid aggravation of the symptoms, or supervention of new and more formidable ones, by which he is soon carried off; and if he survives these, he may live for a long time, bed-ridden, dropsical, and a true paralytic."

Of the causes of the disease so very little is known that we need scarcely do more than allude to them. It prevails more among the Mussulmauns than the Hindoos, and evidently runs in families, but it is not suspected of being contagious. Something, however, seems to have been made out by Mr. Malcomson as to the pathology of beriberi, which he has rendered it probable consists in disease of the lower portion of the spinal cord; indeed, he has given some dissections which clearly prove the parts to have undergone a kind of wasting. He says, describing such a case, "the substance of the cord was perhaps softer than usual, and the nerves of the cauda equina appeared red, but on examination it was found that this arose from an almost total decay of the white nervous matter, allowing the vessels of the membrane to shine through, and not from any unusual vascularity. There were no marks of previous severe inflammation of the membranes." This state of the spinal cord will satisfactorily account for the paralytic condition of the lower extremities, as well as for the remarkable changes which the urinary function undergoes.

The paralysis is thus described—

"Palsy appears to be the most constantly present of all the muscular symptoms, generally coming on slowly, but now and then very rapidly, the knees being suddenly so weakened, that the patient on awaking from sleep has been unable to rise without assistance; in the majority of recent cases spasmodic rigidity is also present, and in a few, the flexor muscles were permanently contracted. The recti muscles of the abdomen, in one instance, felt hard and contracted, the patient comparing them to sticks. The cramps are most distressing in the calves of legs and soles of feet, and in one example the muscles of the back were thrown into such rigid contraction as to give the appearance of opisthotonos."

And again, in a report by Dr. Herklots, a surgeon in the Indian army:—

"Though the patients are sometimes first affected with a sense of stiffness of the joints, previous to any other symptom supervening, yet in the disease as it usually occurs here, the patient generally first complains of pain, occasionally confined to the joints but more frequently affecting the muscles of the legs and feet; (or he is first of all affected with spasms); to these in a few days succeed œdema, then numbness, spasms, diminution of muscular power, &c. But this is not the course the disease invariably follows; at times the patient gets up from his sleep of a morning with a slight numbness in his feet, which some-

times very gradually, at other times rapidly ascends upwards, occasionally accompanied with œdema, which then keeps pace with the numbness, extending in some cases throughout the whole body. At other times, again, the patient goes to bed in perfect health, and awakes in the morning, to his great surprise, with a weakness or total loss of power in the motion of his limbs. A few days after, the patient complains of more or less violent spasmodic contractions of the muscles and tendons, in the generality of cases confined to the hamstring muscles, calves of the legs, or tendines achilles; but sometimes affecting all the muscles of both the upper and lower extremities, and in a few rare instances, almost every muscle in the body. In one case, the patient complained of spasm at the pit of the stomach; in another, of a feeling of hardness in the calves towards the evenings, which grew soft again in the mornings following; during this period sometimes, the patient complains of pain in the affected parts, or of all the *joints* of the body or throughout the whole system; at other times only of soreness on pressure.

"The diminution or loss of power of voluntary motion occurs in very different degrees; in the case of Cumboo, the patient had not the slightest power to move himself; could not raise an arm or a finger, much less turn himself from one side to the other: in this case it was something more than paraplegia; it consisted of total loss of power (we may say) of almost every muscle in the body. More frequently, however, the weakness is in the hip, knee, ankle, finger, or toe joints, either singly or in combination. If œdema is present, these commonly don't show themselves till the swelling goes off; and as the latter symptom gradually disappears, the former progressively increases. If the loss of muscular power exists in the loins or hip-joints, the patient is unable to get off his cot or move his lower extremities; if lifted up by a couple of people he is like a piece of dead weight, perfectly unable to afford the smallest support to his body by his legs. If the loss of power is not quite so great, when raised by assistants, it is as much as he can do to lift his legs alternately and place them forward as in progression. When the loss of power exists in the knee joints, it is then only that the patient has the gait of the sheep; and if in that case it exists in a still severer degree the patient has a tottering in his walk; and th ugh he uses a stick as a prop, he is every moment in danger of falling, unless he obviates the tendency by particular attention, for kis knees give way under him. The loss of power is sometimes confined to the ankle-joints; in which case, as the patient lifts his legs off the ground, the feet dangle from the ankles, as a broken bone does from a fractured part; the patient has no power to bend the feet, and on resting the body on one foot it bends outwards and gives way under the weight; in several of these cases, the patients felt exactly as if, at every step, some one gave them a push from behind and they were in danger of stumbling. Loss of muscular power in the finger and toes is generally most severe in the thumbs and great toes; these have in several instances been perfectly immoveable. Sometimes all the fingers and toes of both hands and feet have lost their power of motion, (the patients being perfectly unable to bend their fingers so as to approximate them with the palms of their hands, or raise their toes off the ground); while at other times, only one or more are so so affected. Some of these have also acquired, in a few cases, a considerable degree of stiffness, and they could not be brought in contact."

This will serve as a description of the characteristic symptoms of this singular disease.

The changes in the urine are analogous to those which take place in other cases of spinal disease. It is usually more or less turbid when voided; but sometimes becomes more so after having stood for some time. The presence of ammonia soon becomes evident. The complication of affections of the heart and dropsy are elaborately detailed, and we know of no account of this disease in which nearly so much information regarding it is to be found; our space, however, only admits farther of a short analysis of the treatment, the account of which is far from satisfactory—not as to Mr. Malcolmson's details, but as to the general results of the remedies adopted.

Bleeding, which has been very strongly recommended by some, is held by our author to require very great caution, and only to be admissible at the onset of the disease; if the case be chronic, "the relief from bleeding is little mani-

fested, notwithstanding the hardness of the pulse." Mercury seems only to be useful when there exist inflammatory symptoms, requiring bleeding: the nervous symptoms are increased by it, and the general inference deduced from actual experience is much against it.

Purgatives are often of essential service, and of these the compound powder of jalap has been found to answer best.

Diuretics are of much assistance in removing the œdema, and especially in preventing the spread of the anasarca upwards; but "to this their usefulness is limited." Of diuretics the supertartrate of potass is most strongly recommended; and this, it will be observed, is in keeping with the purgative above recommended. Stimulants, particularly laudanum in combination with ether and ammonia, are to be diligently employed where there are paroxysms of dyspnœa coming on suddenly, especially if they be of spasmodic character, and attended with feeble pulse: the extremities and trunk are also to be rubbed with stimulating liniments. Cinchona has no power upon the proper symptoms of beriberi, but is sometimes useful in those cases in which ague is combined with them. Counter-irritation constitutes a very important part of the treatment. Blisters to the spine are spoken of with more commendation than cupping, or than other forms of exciting cutaneous inflammation.

Exercise and change of air do very little for the patient, and no more for his convalescence than on the general principle of tending to remove the debility which remains after any severe disease.

Galvanism, from want or imperfection of instruments, has been used but seldom, and the results are only such as show the propriety of making farther trials of this agent.

In conclusion we may remark, that the work contains a great deal of original and valuable information, but that it is very indifferently arranged, and embarrassed by digressions,—imperfections which the author might remove in a future edition, without much trouble to himself, and with great advantage to the reader.

The subject is interesting, and one about which we have very little information of a satisfactory nature—at least in this country.

Examen des Doctrines Médicales et des Systèmes de Nosologie de MM. Laennec, Louis, Andral, Lallemand, Bouilland, &c. Par M. F. J. V. Broussais. Deux tomes. Bruxelles. Dulau.

We have here a handsome reprint, in two very neat little volumes, of the celebrated critique by the founder of what is called *physiological medicine* in France. The name of Broussais is famous far and wide; yet the appearance of the *Examen* in its present popular shape cannot fail to extend the author's celebrity further still. The work itself is well known, being an able *resumé* of the views of almost all the eminent French nosologists of modern times, shewing how far they coincide with the Broussaian principles. Prefixed to the critical portion of the work we have a lucid exposition of the doctrines of the author, stated in 468 propositions, or aphorisms; so that the whole may be looked upon as a compendium of physiology, pathology, and therapeutics, peculiarly French.

MEDICAL GAZETTE.

"Licet omnibus, licet etiam mihi, dignitatem *Artis Medicæ* tueri; potestas modo veniendi in publicum sit, dicendi periculum non recuso."

Cicero.

HOW TO DEAL WITH QUACKERY.

We are not very sanguine, nor ever have been, about the possible extirpation of quackery from this or any other country. Let laws do their utmost—let pains and penalties be enacted, till there scarcely seem a loop-hole left for the most clever charlatan to gain admittance into the community,—still, as long as there are knaves and dupes in the world, charlatanism, under that or some other name, must flourish. Perhaps when Astræa returns with another golden age, quackery will be seen and heard of no more: but we fancy we must wait patiently until then.

It is rather amusing to notice the

grand scheme of a worthy contemporary of ours, by which he intends to give a complete *coup de grace* to quackery in England. Medical practitioners throughout the country are to enter into a solemn league and covenant to give the rampant monster no quarter; they are to have a grand central Board in the metropolis, always sitting, attended by well-paid functionaries, for the despatch of business; and that business is chiefly to consist in the gathering of information against the enemy, publishing that information, and disseminating it throughout the land in the shape of tracts, like those scattered abroad with such signal success by the Anti-gin-drinking societies. For this laudable purpose, and in furtherance of so wise an expedient, all the legally qualified medical men in England are to *subscribe*, and to form a body, the ramifications of which may be found everywhere, — the whole to be most appropriately designated by the imposing title of the Anti-Medical Quackery Society.*

A more ridiculous project, we believe, has rarely been devised. Legitimate practitioners, forsooth, are to form themselves into a regular *union* for the suppression of charlatanism, and to don the title of the Quackery Society—anti-medical, too. Was ever such stupid short-sighted blundering? Why, if the great body of quacks were themselves to combine against the profession, they could not adopt a more appropriate title than the Anti-medical Quackery Society. Yet such is the sort of union of practitioners seriously recommended by our contemporary, and for the organization of which a liberal subsidy is to be raised. Who but the wiseacre who suggests the scheme is ignorant of what would be the result of such a combination? A rich harvest to every daring empiric, bold enough to face the league of medical practitioners. To those other merits and qualifications which ground his present claims to public patronage, would then be added that most captivating one—of persecution. The quack would immediately hold the respectable rank of a martyr to the public cause, and would reap his profits accordingly. The practitioner, on the other hand, acting in concert with the Anti-quackery Society, would stand in the odious light of a monopolist—an enemy to improvements in science—and, worse than all, a self-interested opponent of what would be insisted on as the people's right to choose whom they please for their medical attendants. A brighter prospect could not be desired by quacks, charlatans, and empirics of every description, than this sort of conspiracy against them by regular practitioners. The tables would be completely turned: the Morisons, the Eadys, the successors of St. John Long, and the whole tribe of mountebanks, would then be in all their glory---raised to a pitch of importance, which they never before even dreamed of. Yet the wight who has found out this wonderful scheme of putting down quackery — by instituting his Anti-Medical Quackery Society—cannot see so plain a result. Can any mole be blinder?

It is too absurd to waste time in pointing out the silliness of such a project. Quackery can never be suppressed by authority, by persecution, or by force of law. The experiment has been tried again and again. There are strong laws against quackery in France; yet no where does the charlatan thrive with more baleful luxuriancy. In countries, too, such as Prussia and Austria, where the form of government is in a great measure despotic, at least decidedly military, enactments have been made for the extirpation of quackery;

* See Lancet, March 12, 1836.

yet all to no purpose. Certain simple-minded persons, however, think that the object might be accomplished in *this* free country—where it is the jealous pride of all ranks to do as they will with their own—and particularly, to be "doctored" in whatever way they think proper!

What, then, it may be said,—is nothing to be done to check the monstrous evil? Are the growth and spread of quackery to proceed without any effort to control them? Our views on this head have often been stated to our readers. We are the last to advocate anything like a passive indifference on the subject, and more than once have we maintained that the prominent position occupied by the charlatans of the day is mainly owing to the apathy of the regular practitioner. This, however, is far from holding that medical men should combine, in the form of quackery or anti-quackery societies. It by no means follows that because we would have the legitimate member of the profession up and stirring for the maintenance of his rights and the repression of intruders, we should therefore urge him into the extreme foolish predicament of *conspiring* to put down his opponents—conspiring with his brethren in the face of the public—and thereby giving the strongest possible hold to the obnoxious party to secure their usurped position.

What we have all along recommended is this—that medical men should no longer make a merit of their contemptuous indifference towards quackery: reason there is none why their voices should not be uplifted on every occasion where charlatanism in any shape comes before them; and they should remember that if *they* are silent, there is no other source of censure to keep the mischief in abeyance.

The proper mode, therefore, of proceeding, naturally suggests itself: in the first place, it would seem advisable to put off that apathetic bearing which is so detrimental to the cause; and, secondly, for each member of the profession *individually* to exert himself within the sphere of his particular influence. Let the legitimate practitioner avail himself of the occasion, whenever it offers, of shewing up charlatanism in its true light; let him point out the dangers which attend the destructive use of nostrums; and, above all, let him clearly demonstrate the folly and wickedness of those who pretend to cure all diseases, in all constitutions, and in all circumstances, by one universal remedy. It is in this way only that that sort of knowledge can be diffused, which, if anything can, will put quackery to the rout. It is useless to expect aid from the legislature, encouragement from the press, or any immediate support from the "expanded intellect" of the age. *Aide-toi* should be the maxim of every medical man, when he has quackery to deal with; and the true way of putting the maxim into practice, is not by seeking vicarious assistance, but by using every rightful personal exertion.

Another rule of conduct we would also beg to suggest, though it is properly, perhaps, only a corollary of the preceding; and that is, never to give countenance to any *patent* nostrum—never to grant permission to a patient asking our leave to take, or continue to take, any pills, boluses, cordials, essences, or plasters, sold stamped in the shops as specifics. We are convinced that the easiness with which medical men are induced to give their consent, and to tolerate such practices, has a potent effect in the extension of the mischief.

Such are the short and easy methods which we recommend for dealing with the quack nuisance. We have long since advocated the plan; and are led to recur to it now, partly on account of

the formidable advances lately made by the evil in question, and partly because we perceive a foolish guide attempting to mislead the profession. To all such as might be simple enough to fall into the snare, we beg to repeat our warning: if they would contribute to the suppression of quackery, let them really take the matter into "their own hands;" let them employ *personally* their best zeal and diligence, but take heed how they patronize anti-quackery unions.

PARLIAMENTARY MEDICAL COMMITTEE.

We understand that the Medical Committee will be revived, in order to enable Mr. Warburton to report upon the evidence taken during the last parliament. That gentleman is again engaged on the subject, and is collecting further information. We hear that some difference of opinion exists between him and the government as to the new arrangements connected with the medical profession.

APPOINTMENT OF DUPUYTREN'S SUCCESSOR.

M. SANSON.

The important professorship of *Clinique Externe* has at length been committed to M. Sanson, after a well-contested *concours* of about two months' duration. This gentleman was all through the popular favourite, and acquitted himself in every stage of the contest with marked success. Yet the mode in which the judges voted for his appointment is curious. At the first *tour de scrutin*, MM. Marjolin, Roux, Lisfranc, and Murat, voted for M. Blandin; MM. Velpeau, Richerand, P. Dubois, and J. Cloquet, for M. Berard; MM. Chomel, Gerdy, and Reveillé Parise, for M. Sanson. But the second *tour* brought all M. Berard's votes to M. Sanson; M. Murat also gave his vote in M. Sanson's favour: so that the election was carried by eight to three against M. Blandin. It is worth adding, that M. Lisfranc supported the latter candidate throughout. Such is a specimen of the *concours*.

M. PARENT DU CHATELET.

Medical science has suffered a severe loss in the death of this gentleman, which took place recently at Paris, from an affection of the brain. M. Parent du Châtelet was chiefly distinguished in the department of public *hygiène;* his works insured for him a high and extended celebrity; and his reputation, founded on his persevering and indefatigable labours, will long remain permanent and solid.

CRUSHING THE STONE IN THE BLADDER.

To Sir Benjamin C. Brodie, Bart.

My dear Sir Benjamin,

I am very much obliged to you, and I shall do what you suggest.

In our day it is very difficult to perform our duty to the hospital pupils, and to be on our guard lest we hurt some one's feelings by having our unpremeditated expressions printed.

Ever truly yours,

Charles Bell.

Brook-Street,
March 23, 1836.

On reading your note a second time, I think you should permit me to send it to the Gazette, it is so creditable to the Baron.

To Sir Charles Bell, K.H., &c. &c.

My dear Sir Charles,

I have been reading your very interesting lecture on the operation of crushing stones in the bladder, in the last number of the Medical Gazette; and I think it right to trouble you with the following observations on one or two points referred to in it.

In the case which I attended with Dr. Hume, and in which we afterwards called you to assist us in consultation, Baron Heurteloup used, not the three-clawed instrument, which you so justly reprobate, but the curved sliding forceps, similar (as I apprehend) to those which you recommend, and which you employed in the operation described in your lecture. Unfortunately the steel had not been properly tempered, and, in consequence, instead of completing the work of crushing the stone, the blades bent. I am sure that you will agree with me in thinking, that it would be hard to throw the entire blame of such an accident on the operator. I have never heard of a similar accident having occurred since.

The first person who actually applied

the curved sliding forceps to the purpose of crushing stones in the bladder, was Baron Heurteloup. This I know to have been the case; and I cannot but think that the profession and the public are very much indebted to him for this very great improvement in the operation. In fact, he made that easily practicable, which was the next thing to being impracticable in M. Civiale's operation with the straight three-clawed forceps.

The principal improvement made by Mr. Weiss is that of appling the screw instead of the hammer, for the purpose of crushing the stone; and in my judgment a great improvement it is; but still the principle of the operation is the same, wheth r it be performed with Mr. Weiss's screw, or Baron Heurteloup's hammer.

Being fully assured as I am, that it is your earnest wish to deal justly and generously by every one, I do not doubt that you will excuse the liberty which I take, as an old friend, in correcting these mistakes into which you have accidentally fallen.

Believe me to be always,
Yours most truly,
B. C. Brodie.

14, Saville Row,
March 22, 1836.

INTERVIEW

OF A

DEPUTATION OF THE BUCKS MEDICAL ASSOCIATION WITH LORD JOHN RUSSELL.

PROTEST AGAINST THE REPORT OF THE POOR-LAW COMMISSIONERS.

To the Editor of the Medical Gazette.

Sir,

I beg permission to forward you, for early insertion in your journal, an abstract of the minutes of a meeting of the Bucks Medical Association, a copy of a Protest drawn up at the desire of that meeting, and a brief account of the reception and proceedings of a deputation which waited on Lord John Russell with the Protest.

I have the honour to be, sir,
Your most obedient servant,
Robert Ceely,
Hon. Sec.

Aylesbury, March 19, 1836.

At a meeting of the Bucks Medical Association, held at Aylesbury, on the 23d November last, — Richard Steel, Esq., Berkhampstead, in the chair,—it was resolved —

"That a Protest against the 25th section of the first Annual Report of the Poor-Law Commissioners should be drawn up by the committee, which, after signature by members of the profession *in* and *near* the county of Bucks, should be presented by a deputation to Lord John Russell."

It was also resolved—

"That Mr. Nathaniel Rumsey, of Beacon field; Mr. William Robarts, of Burnham; and Mr. Robert Ceely, of Aylesbury, do form the deputation for presenting the said Protest."

In compliance with these resolutions, the following Protest was drawn up, and received the signatures of 115 medical practitioners, including those of several physicians:—

To the Right Hon. Lord John Russell, His Majesty's Principal Secretary of State for the Home Department, &c. &c.

We, the undersigned, practitioners in medicine and surgery, in and near the county of Buckingham, beg permission to submit to your lordship our PROTEST against certain statements contained in the 25th section relative to medical relief) of the first annual report of the Poor-law Commissioners for England and Wales; on the following grounds:—

1. Because those statements are calculated unjustly to impress the public mind with sentiments of disapprobation, jealousy, and suspicion, towards the medical profession.

2. Because they are intended unfairly to reconcile the community to the adoption of a system of "medical relief" incompatible with a humane consideration for the sick poor, and subversive of the proper ends of medical exertion.

3. Because, instead of impugning the character of the medical profession in general, and of the class of parochial surgeons in particular, candour and justice would have made some mention of the vast amount of their laborious and gratuitous services.

4. Because the measures adopted "as a check to the general expense of medical relief" are not warranted by the previous well-known inadequacy of the remuneration for medico-parochial duties; neither are they calculated "to secure to the paupers the best treatment."

5. Because the omission from the old medical contracts, of any provision for

non-parishioners, arose from the absence of any legal claim for such provision, and from the consequent want of concert and reciprocity of arrangement among parishes, and not from any "expressed or complied condition" with the contractors.

6. Because we are satisfied that there is no ground for alleging, that the charges for non-parishioners, "in the great majority of instances," were at the "highest rates," but that, on the contrary, they have been much below what professional usage and public consent have long and equitably sanctioned.

7. Because, if in very rare instances, exorbitant charges were made for non-parishioners, adequate protection existed; while, on the other hand, our moderate claims for such cases, promptly attended without a written authority, (to avoid serious inconvenience to the patient from delay,) have been in a great proportion of instances dishonourably refused, and, therefore, irrecoverable.

8. Because the alleged disgraceful collusion with inferior parish officers is unknown to us, and we believe can be completely disproved by the profession at large; which is entitled to require not only the ground of such a charge, but the exposure of any perpetrator of so nefarious a practice.

9. Because the inference drawn in the report, that a medical education recently acquired at the schools is equivalent to the knowledge resulting from long practice and experience, is not sanctioned by reflection, courtesy, or justice; but is strangely opposed to universal practice and opinion.

10. Because right feeling and sound policy alike dictate that medico-parochial duties, from their variety, importance, extent, and great responsibility, should be entrusted to those who have previously established their moral and professional character, and have local ties in the neighbourhood.

11. Because it is not true that "the interests of the public and of the profession" are consulted by the system of medical contracts by "tender," since it affords no evidence of the general fitness of the "tenderer" for so important an office.

12. Because although it is asserted "that the candidate in fixing his own terms consults his own interest," yet it cannot be admitted "that he considers the interests and advantages of his profession;" especially, when influenced by the inducement of "obtaining more profitable practice," unjustifiably held out in the report, he is led to attempt an invasion of the private rights and justly acquired interests of his medical brethren.

13. Because the mode of obtaining the appointment, and the degrading conditions of its tenure, divest it of all the supposed "credit," and render it to the experienced and established practitioner merely a choice of evils.

14. Because the "inducements to the acquisition of the appointment," by so reprehensible a mode, are calculated to allure a succession of unknown and needy adventurers, rather than to encourage established and experienced practitioners.

15. Because the assumed analogy between the duties and advantages of an "appointment to any of the chief medical institutions of the country," and those of a medico-parochial office, is entirely fictitious.

16. Because lawful associations for the maintenance of private rights, and the protection of legitimate interests, arbitrarily assailed by authority, ought not to be libelled with the opprobrious epithet of "combinations."

17. Because we are prepared to prove that the system of "medical relief," adopted so much to the satisfaction of the Poor-law Commissioners, is lamentably deficient, as a prompt, humane, and effective provision for the sick poor.

18. Because such a provision can be devised only by the aid of those who have been long and practically acquainted with the subject; and we, having known and deprecated the abuses of the old system, venture to claim a right to express our opinion, that it is not consistent with policy or justice to attempt the partial removal of those abuses, by the introduction of a new system abounding with still greater evils, and fraught with injury to the poor of a nation long celebrated for its justice and philanthropy.

Clarance, Thaxted, Essex; John Green Bishop, Maidenhead; Charles Williams, Maidenhead; Richard Goolden, Maidenhead; John Westell, Maidenhead; Matthew Cooper, Windsor.

The deputation, which was kindly accompanied by Sir William L. Young, Bart. M.P., and William Rickford, Esq. M.P., had the honour of an interview with Lord John Russell, on Thursday last, the 17th instant, at the Home Office.

After stating to his Lordship the strong feelings excited in the profession by the tenor of the 25th section of the Commissioners' Report, the deputation proceeded to explain the most important points in the Protest. They then detailed the various grievances existing under the arrangements of the Commissioners relative to "medical relief," as they affected the sick poor, the community, and the profession.

They particularly dwelt on the evils arising out of the appointment, in many instances, of a reduced and insufficient number of medical officers to greatly extended districts;—on the various modes of contracting, especially by tender;—on the general inadequacy of compensation allowed;—on the injuries inflicted on practitioners who declined to accede to the terms and conditions imposed;—on the unjust and injurious subjection of the medical to the relieving officer;—on the utter disregard of the representations and advice of medical men;—on the unmerited and degrading treatment they have generally received from the authorities;—and on the injury that must inevitably accrue to the poor, to the public, and to medical science.

Facts were then stated in illustration and confirmation of the several points alluded to.

The deputation disclaimed being under the influence of factious or unworthy motives; strongly insisted on the sacrifices continually made by the profession in behalf of the needy and indigent portion of the community; and declared the willingness of medical practitioners to acquiesce in arrangements not involving a compromise of the respectability of the profession, or the sacrifice of its just interests.

They contended and proved that the evils arising out of the present scheme of medical relief are of such magnitude and importance as to claim his Lordship's attention; and they were willing to hope that this earnest appeal for his Lordship's interference would be successful in procuring the substitution of a measure founded on liberal and enlightened principles.

Sir William Young, though approving of the general operation of the New Poor-Law Amendment Act, thought the medical arrangements under it stood in great need of revision.

His Lordship, having perused the Pro-

test, and partially attended to the observations and arguments of the deputation, stated, "*that he had not heard of such complaints from any other quarter;*" but promised to see the Commissioners, and make inquiry into the subject.

The deputation assured his Lordship that the medical journals teemed with such complaints, and that he might take the present manifestation of them as a sample of the general feelings of the profession. They accounted for the delay in the presentation of this their Protest; begged permission to leave with his Lordship a concise "statement of the complaints of medical practitioners against the provisions for medical relief adopted by the Poor-Law Commissioners;" and thanking his Lordship for his polite attention, withdrew.

SUGAR POISONED WITH OXIDE OF LEAD.

By C. T. Jackson, M.D.

During the past winter and spring season, a number of persons, said to amount to upwards of a hundred in number, in the town of Calais, Maine, have suffered from a disease of the bowels, of a violent character, resembling *colica pictonum* of the severest kind. Three of the individuals have died in consequence of this disease, after a protracted and most distressing illness; several others are still in a very critical state, and have suffered more or less from paralysis of the extremities. Through the kindness of one of the sufferers, I have been favoured with the names of forty-eight individuals who are still sick with this disease.

The cause of this distressing malady has been carefully examined into by Dr. S. S. Whipple, of Calais, and through his exertions suspicions were finally fixed upon the sugar which had been used in the families of those who suffered; and it was ascertained that the only article of which they had all partaken, was sugar obtained from one importing house at St. Stephens, N. B. It was furthermore observed, that those persons in the families where the disease prevailed, who did not make use of sugar, escaped altogether, while those who indulged most freely in its use suffered the most severely. Thus the chain of evidence was complete against the sugar, and the disease, supposed at first to be an epidemic, is in the end proved to arise from poison. Five or six of those persons who were subject to this colic, set out for Boston for the purpose of obtaining medical advice; one, a young lady by the name of Darling, died on board the packet, under the most distressing symptoms, attended with paralysis of the limbs. The other passengers are undergoing medical treatment in this city, and still bear the marks of great suffering and extreme emaciation, the countenance in every one whom I have seen showing that peculiar expression which accompanies disease of the abdominal viscera.

I have minutely examined four of the sufferers, and from them have learned the foregoing particulars. It appears that the sugar was brought from Barbadoes late last autumn, and was sold by an importer at St. Stephens, who supplied the trade at Calais. It was also ascertained that the captain of the ship who brought out this sugar had a small adventure of the same kind, and that he, and those to whom he sold his sugar, suffered from this disease.

After collecting the above evidence against the suspected sugar, it was thought advisable to make a chemical analysis of it. Four parcels, consisting of about a pound each, were put in my hands by Mr. Lee and Captain Rodgers, with a request that I should make an analysis of each of them, and ascertain positively whether they contained poison or not.

The parcels were marked Nos. 1, 2, 3, and 4, and were subjected to analysis in the order of their numbers.

My suspicions and those of Dr. Whipple were fixed on oxide of lead as the poisonous ingredient, and the results of the analysis prove that this opinion was well founded.

They also prove that a small quantity of this poison, when taken daily, although no immediate disturbance is felt, produces great derangement of the system, and induces a most dangerous and painful disease, which lingers long in the constitution after the use of the deleterious article has been suspended. How often do people exclaim that certain articles are not poisonous, because they have sometimes partaken of them with impunity, when we know that if persevered in, disease and death must be the consequence of their temerity!

I annex the subjoined extract from my laboratory notes.

June 7th, 1835.—Four parcels of brown sugar were handed to me by Captain Rodgers and Mr. Thomas Lee, for chemical analysis. They are marked Nos. 1, 2, 3, and 4, and weigh about a pound each. No. 1 is evidently from a different lot from the other samples. It is of a lighter yellow colour, and coarse grained; while the others are much darker and smaller grained, and in lumps of a still deeper colour. There is nothing peculiar in the taste or appearance of any of the samples

that would cause any suspicion to be raised against the quality of the sugar.

Analysis.—The object of the analysis is to determine if the sugar contains any oxide or salt of lead or copper.

Five hundred grains of the sugar No. 1, burned to cinders in a platina capsule, the cinders crushed to powder in a Wedgewood mortar, and then burned to ashes in the capsule. The ashes were placed in a green glass flask, and digested with nitric acid, and evaporated to dryness; then treated with water and filtered. The filtered solution was placed in a flask, and a current of sulphuretted and hydrogen gas passed through it until the liquor was saturated. No precipitate took place, from which it will appear that this sample does *not* contain any lead or copper.

I have since learned that this sugar was sent for the purpose of ascertaining if it were free from poison, and was not of the kind used by the family at the time they suffered from the disease.

Five hundred grains of No. 2, which came from the house of Mr. Lee, were treated exactly as No. 1; and when the sulphuretted hydrogen gas was passed through it, a copious precipitate of sulphuret of lead took place, which being collected on a filter, washed, dried, and weighed, amounted to 1·6 grains; equal to 1·38 grains metallic lead, equal to 2·337 grains oxide of lead. This will give nearly 38 grains of oxide of lead to the pound of sugar.

Five hundred grains of No. 3, treated in like manner, gave a precipitate of sulphuret of lead, the weight of which is precisely the same as that obtained from No. 2.

No. 4, sugar from Mr. Darling's family. Five hundred grains, treated like No. 1, gave, when sulphuretted hydrogen gas was passed through it, sulphuret of lead in equal weight to that from No. 2. The sulphuret of lead obtained from Nos. 2 and 4 was reduced before the blowpipe to metallic lead. A portion of each of the precipitates was examined by tests for copper, and none discovered.

The lead in this sugar may be either in the state of acetate, malate, or saccharate of the oxide of lead, the sugar combining with it so as to form a chemical combination. How this sugar became contaminated with lead, I am unable to say. There is no suspicion of criminal design attached to any one, and it is probable that leaden reservoirs were used for the syrup, on account of the comparative cheapness of the metal, and that the free acids in the juice of the cane corroded the lead, and thus produced the poison, which crystallized in combination with the sugar. The dreadful effects of this poison should by all means reach the sugar planters, who distribute so noxious an article to the people of many countries, and must produce consequences at which humanity shudders. If the planters continue to manufacture this poisonous compound, and send it abroad regardless of the consequences, after they learn how much suffering it has caused, (which I am not willing to suppose they will do), they will become criminal in the eye of British law, and liable to the severest penalties.

Indeed, we may feel assured, that as soon as they know the effects of their sugar, they will immediately examine into the source from whence the poison was derived, and prevent a continuance of the evil. Their own *interest* would cause this to be done, even if they were not impelled by higher motives; for their sugar would soon have a bad reputation, which would destroy its sale in the market. The researches into the cause of this disease eminently show the advantage of rational medicine over empiricism; for the empiric would never have traced the disease to its remote cause by a connected mode of research, and consequently would have been unable to learn the cause of the malady, and its method of cure. The symptoms in the cases all pointed to lead as their cause, and chemical analysis has confirmed the truth of this opinion. The cause is thus found out and removed; and rational medical treatment will soon restore the surviving sufferers to health.

It is surprising that *colica pictonum* is not a more frequent disease than it is, considering the numerous applications of lead to domestic use. Indeed, I have several times been able to trace the origin of this disease to the use either of leaden reservoirs for water, or leaden suction tubes in wells, where the water was charged with carbonic acid. Such wells are common in Boston, and I have several times been called to witness the effects of water charged with this gas, on lead pipe, which had been corroded entirely through in the course of two years after it was placed in the well. Whenever water contains carbonic acid, lead suction pipe should be carefully avoided, and block tin substituted in its place; for lead is not only soon destroyed by such water, but a dangerous poison is produced, capable of slowly undermining the most vigorous constitution*.

* Medical Magazine, June 15, 1835; and American Journal of Medical Sciences.

NEW METHOD OF OPERATING FOR CATARACT.

Dr. Jungken makes the following remarks:—Guided by experience, which has shown that the chrystalline lens is frequently absorbed when deprived of its capsule, and freely exposed to the action of the aqueous humor, I have been led to try a new method of operating, which, with less lesion of the parts than is required for extraction, is calculated, neverhteless, to give us surer results than follow the breaking down of the lens. The principle of this operation consists in removing the anterior part of the capsule, and bringing it away entirely from the eye, while the crystalline lens itself is left *in situ*, the whole of its anterior surface being thus exposed to the action of the aqueous humor.

The operation was performed, for the first time, on a weak and emaciated girl. The cornea was divided, by means of a cataract knife, near its external edge, at half a line from the sclerotica, by an incision of from three to four lines, directed parallel to its circumference. By this opening, a small fine penetrating needle was introduced through the pupil (which had been previously dilated) into the posterior chamber; the capsule was seized at its inner edge, and an attempt made to tear off round its circumference, with a view of extracting it through the wound. This last part of the operation succeeded but imperfectly, and it was necessary to introduce a small pincers, by means of which the capsule was removed in portions. The immediate consequences of the operation were unsatisfactory, but the lens was ultimately absorbed. The particulars are detailed in *Rust's Magazin.*

NITRO-MURIATIC ACID BATH.

M. Schlesinger has recently employed this remedy in chronic disease of the liver, as well as in a variety of cases dependent upon defective biliary secretion. His formula is—muriatic acid, ℥iij.; nitric acid, ℥ij.; water, ℥vj.; to be divided into three portions, one of which is to be mixed with from 15 to 50 lbs. of warm water. This is used as a foot-bath, for 20 to 25 minutes before going to bed. Gentle laxatives are used at the same time.—*Hufeland's Journal.*

TREATMENT OF EPILEPSY BY INDIGO.

M. Noble is at present engaged in experiments on the treatment of this disease by the above method. By aid of this substance administered gradually in doses of three or four drachms, under form of an opiate, three persons seriously affected with epilepsy have been cured. The first subject was a young man, aged 18 years. The fits occurred every eight or ten days, for ten years. Two months have now elapsed without their recurrence. The second person was a young woman, aged 20, who had been affected for sixteen years, and in whom the fits occurred ten or twelve times a day since the period of menstruation. In six days the fits disappeared under the treatment by opiate of indigo. The third subject was a woman, aged 58, suffering under epilepsy for twenty years; the fits occurring four or five times a day. In four days the treatment by the opiate of indigo triumphed over the disease. In the first patient the indigo, raised to three or four drachms, produced some spasms analogous to those produced by strychnine; with two others an active diarrhœa set in, when the medicine was carried to the above dose.—*Arch. Gén.* Nov. 1835; and *Dublin Journal.*

PROFESSOR DEWEES.

This eminent practitioner and teacher, who has for several years filled the obstetric chair in the University of Pennsylvania, with the highest honour to himself and advantage to the school, has been compelled by illness to resign his professorship. He is at present in the Island of Cuba, in the hope of benefitting his health by a winter's residence in a warm climate; and we are happy to state that recent letters from him afford the pleasing prospect of these hopes being realized.—*American Journal.*

DR. HOSACK.

The *American Journal of Medical Sciences* records the death of Dr. David Hosack, whose name was so long connected with the medical literature and practice of America. He died of apoplexy on the 22d of December last; and it is said that the fatal event was induced by the calamitous fire which desolated New York about that date.

ANATOMICAL WAX MODEL OF THE EYE.

At the Royal Institution, on Friday evening, Mr. Schloss, of Great Russell-Street, exhibited a very beautiful wax work of the human eye, enlarged to four diameters. It is not a mere section, vertical or horizontal, but the entire eye, with its membranes, all capable of demonstration by being taken to pieces. The material is of an elastic nature, transparent where it should be, and capable of being handled without any detriment. It appears to be well adapted for the lecture-room.

1835.—THERMOM.—Highest, 81·5, June 10. | Lowest, 16·0, Dec. 25. | RAIN, 33·445. | BAROM.—Highest, 30.55, Jan. 2 | Lowest, 28·70, Oct. 10.

GENERAL OBSERVATIONS.

THE mode of keeping these registers is as follows:—

At *Edmonton*, the warmth of the day is observed by means of a thermometer exposed to the north in the shade, standing about four feet above the surface of the ground; the extreme cold of the night is ascertained by a horizontal self-registering thermometer, in a similar situation. The daily range of the thermometer and barometer is known from observations made at intervals of four hours each, from eight in the morning till the same time in the evening. The weather and direction of the wind are the result of the most frequent observations. The rain is measured every morning at eight o'clock.

At *Cheltenham*, the temperature is ascertained by a horizontal self-registering thermometer, suspended about five feet from the ground, in a north-east aspect; and the observations made at eight o'clock A.M. The pressure of the atmosphere, and the direction of the winds, are registered at eight o'clock A.M., and eight o'clock P.M. The quantity of rain which has fallen is registered at eight o'clock A.M.

CHARLES HENRY ADAMS.

A GENERAL BILL

OF THE

BURIALS, WITHIN THE CITY OF LONDON, AND BILLS OF MORTALITY,

From Dec. 9, 1834, to Dec. 15, 1835.

DISEASES AND CASUALTIES OF THE YEAR.

Diseases.

Abscess	176
Age and Debility	2345
Apoplexy	437
Asthma	879
Cancer	101
Childbirth	277
Cholera	5
Consumption	3662
Constipation of the Bowels	16
Convulsions	1955
Croup	167
Dentition or Teething	445
Diabetes	8
Diarrhœa	36
Dropsy	810
on the Brain	700
on the Chest	85
Dysentery	5
Epilepsy	31
Erysipelas	52
Fever	420
(Intermittent or Ague)	7
(Scarlet)	445
(Typhus)	77
Fistula	7
Gout	93
Hæmorrhage	38
Heart, diseased	144
Hernia	18
Hooping-cough	652
Indigestion	15
Inflammation	1714
Bowels & Stomach	226
Brain	162
Lungs and Pleura	406
Influenza	1
Insanity	165
Jaundice	37
Jaw, locked	9
Liver, diseased	300
Measles	734
Miscarriage	12
Mortification	224
Paralysis	162
Rheumatism	24
Scrofula	12
Small-pox	863
Sore Throat and Quinsey	52
Spasm	71
Stone and Gravel	22
Stricture	12
Thrush	90
Tumor	38
Venereal	6
Worms	13
Unknown Causes	582
Stillborn	966

Casualties.

Drowned	109
Died by Visitation of God	45
Excessive Drinking	19
Found Dead	11
Killed by various Accidents	169
Murdered	3
Poisoned	10
Suicides	41

Buried { Males ...... 10,064 / Females .... 10,451 } Total 21,415

Of the number buried were,

Stillborn	966
Under 2 years of age	5416
2 and under 5 years	2319
5 and under 10	1011
10 and under 20	754
20 and under 30	1424
30 and under 40	1640
40 and under 50	1892
50 and under 60	1816
60 and under 70	1769
70 and under 80	1613
80 and under 90	685
90 and under 100	103
100	3
101	1
102, 104, 105	3

Decrease in the burials reported this year, 264.

APOTHECARIES' HALL.

LIST OF GENTLEMEN WHO HAVE RECEIVED CERTIFICATES.

March 24, 1836.

Samuel Gillett Gilbert, Blofield, Norfolk.
Henry Rickards, Hereford.
George Ambrose Cope, Melbourne, Derbyshire.
John Alfred Lush, Berwick, St. John, Wilts.
Thomas Fletcher Tyeman.
John Wordsworth Savage, Hull.
Robert Latten, Colchester.
John Gurney, Sheffield.

NEW MEDICAL WORKS.

Elements of Medical Jurisprudence. By Alfred S. Taylor, F.L.S., Lecturer on Medical Jurisprudence at Guy's Hospital. Vol. 1, 8vo. 15s.

Report on the Medical Management of the Native (Indian) Jails. By James Hutchinson, A.M., M.R.C.S. 8vo. Calcutta, 1835.

Elements of Agricultural Chemistry; in a Course of Lectures, by Sir H. Davy, Bart. LL.D. F.R.S. Fifth Edit. 8vo. 15s. bds.

Practical Observations on Midwifery. By James Hamilton, M.D., &c. Part I. 8vo. 7s. 6d. bds.

The Physical and Intellectual Constitution of Man considered By Edward Meryon. 8vo. pp. 240.

A Treatise on the Chemical, Medicinal, and Physiological Properties of Creosote; being the Harveian Prize Dissertation for 1836. By J. Rose Cormack. 8vo. pp. 154.

WEEKLY ACCOUNT OF BURIALS,

From BILLS OF MORTALITY, *Mar.* 22, 1836.

Age and Debility	43
Apoplexy	1
Asthma	11
Cancer	2
Childbirth	3
Consumption	51
